BODY CODE PLATE

DESCRIPTION

The Body Code Plate (Fig. 1) is located in the engine compartment on the plenum behind the right side strut tower (Fig. 2). There are seven lines of information on the body code plate. Lines 4, 5, 6, and 7 are not used to define service information. Information reads from left to right, starting with line 3 in the center of the plate to line 1 at the bottom of the plate.

DIGITS 7 THROUGH 23

Vehicle Identification Number

- (Refer to VEHICLE DATA/VEHICLE INFORMATION/VEHICLE IDENTIFICATION NUMBER - DESCRIPTION) for proper breakdown of VIN code.

IF TWO BODY CODE PLATES ARE REQUIRED

The last code shown on either plate will be followed by END. When two plates are required, the last code space on the first plate will indicate (CTD)

When a second plate is required, the first four spaces of each line will not be used due to overlap of the plates.

FASTENER IDENTIFICATION

DESCRIPTION

The SAE bolt strength grades range from grade 2 to grade 8. The higher the grade number, the greater the bolt strength. Identification is determined by the line marks on the top of each bolt head. The actual bolt strength grade corresponds to the number of line marks plus 2. The most commonly used metric bolt strength classes are 9.8 and 10.9. The metric strength class identification number is imprinted on the head of the bolt. The higher the class number, the greater the bolt strength. Some metric nuts are imprinted with a single-digit strength class on the nut face. Refer to the Fastener Identification and Fastener Strength Charts.

HOW TO DETERMINE BOLT STRENGTH

	Mark	Class
Hexagon head bolt	Bolt head No. 4 — 5 — 6 — 7 — 8 — 9 — 10 — 11 —	4T 5T 6T 7T 8T 9T 10T 11T
	 No mark	4T
Hexagon flange bolt w/washer hexagon bolt	No mark	4T
Hexagon head bolt	Two protruding lines	5T
Hexagon flange bolt w/washer hexagon bolt	Two protruding lines	6T
Hexagon head bolt	Three protruding lines	7T
Hexagon head bolt	Four protruding lines	8T

	Mark	Class
Stud bolt	 No mark	4T
	 Grooved	6T
Welded bolt		4T

95IN-4

FASTENER STRENGTH

FASTENER USAGE

DESCRIPTION

FASTENER USAGE

WARNING: USE OF AN INCORRECT FASTENER MAY RESULT IN COMPONENT DAMAGE OR PERSONAL INJURY.

Fasteners and torque specifications references in this Service Manual are identified in metric and SAE format.

During any maintenance or repair procedures, it is important to salvage all fasteners (nuts, bolts, etc.) for reassembly. If the fastener is not salvageable, a fastener of equivalent specification must be used.

THREADED HOLE REPAIR

Most stripped threaded holes can be repaired using a Helicoil®. Follow the vehicle or Helicoil® recommendations for application and repair procedures.

INTERNATIONAL SYMBOLS

DESCRIPTION

The graphic symbols illustrated in the following International Control and Display Symbols Chart are used to identify various instrument controls. The symbols correspond to the controls and displays that are located on the instrument panel.

METRIC SYSTEM

DESCRIPTION

The metric system is based on quantities of one, ten, one hundred, one thousand and one million.

The following chart will assist in converting metric units to equivalent English and SAE units, or vise versa.

TORQUE SPECIFICATIONS

VEHICLE IDENTIFICATION NUMBER

DESCRIPTION - VEHICLE IDENTIFICATION NUMBER

The Vehicle Identification Number (VIN) is located on the upper left corner of the instrument panel, near the left A-Pillar. The VIN consists of 17 characters in a combination of letters and numbers that provide specific information about the vehicle (Fig. 3). Refer to VIN Code Decoding Chart.

To protect the consumer from theft and possible fraud the manufacturer is required to include a Check Digit at the ninth position of the Vehicle Identification Number. The check digit is used by the manufacturer and government agencies to verify the authenticity of the vehicle and official documentation. The formula to use the check digit is not released to the general public.

VEHICLE CERTIFICATION LABEL

DESCRIPTION

A vehicle certification label is attached to the rear shutface of the driver's door (Fig. 4). This label indicates date of manufacture (month and year), Gross Vehicle Weight Rating (GVWR), Gross Axle Weight Rating (GAWR) front, Gross Axle Weight Rating (GAWR) rear and the Vehicle Identification Number (VIN). The Month, Day and Hour of manufacture is also included.

All communications or inquiries regarding the vehicle should include the Month-Day-Hour and Vehicle Identification Number.

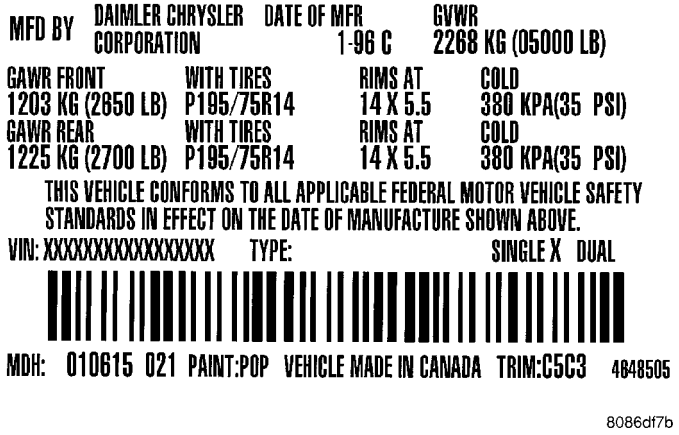

Fig. 4 VEHICLE CERTIFICATION LABEL - TYPICAL

E-MARK LABEL

DESCRIPTION

An E-mark Label (Fig. 5) is located on the rear shut face of the driver's door. The label contains the following information:

- Date of Manufacture
- Month-Day-Hour (MDH)
- Vehicle Identification Number (VIN)
- Country Codes
- Regulation Number
- Regulation Amendment Number
- Approval Number

VECI LABEL

DESCRIPTION

All models have a Vehicle Emission Control Information (VECI) Label. Chrysler permanently attaches

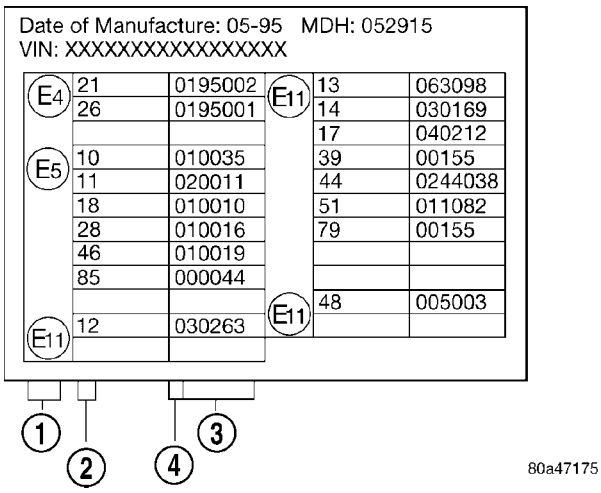

Fig. 5 E-MARK LABEL

1 - COUNTRY CODE
2 - REGULATION NUMBER
3 - APPROVAL NUMBER
4 - AMENDMENT NUMBER

the label in the engine compartment. It cannot be removed without defacing information and destroying the label.

The label contains the vehicle's emission specifications and vacuum hose routings. All hoses must be connected and routed according to the label.

MANUFACTURER PLATE

DESCRIPTION

The Manufacturer Plate (Fig. 6) is located in the engine compartment on the passenger side rear corner of the hood. The plate contains five lines of information:

1. Vehicle Identification Number (VIN)
2. Gross Vehicle Mass (GVM)
3. Gross Train Mass (GTM)
4. Gross Front Axle Rating (GFAR)
5. Gross Rear Axle Rating (GRAR)

INTERNATIONAL SYMBOLS

DESCRIPTION

DaimlerChrysler Corporation uses international symbols to identify engine compartment lubricant and fluid inspection and fill locations (Fig. 1).

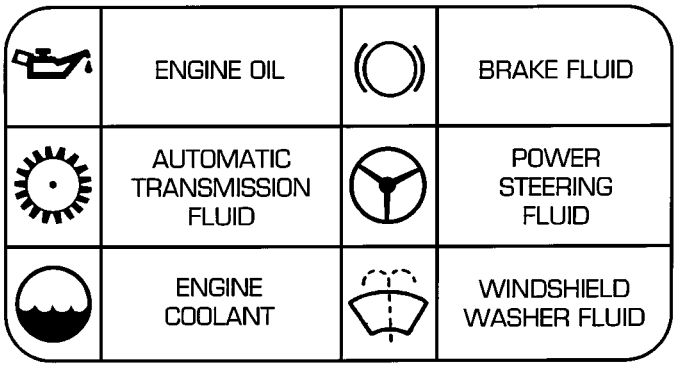

Fig. 1 INTERNATIONAL SYMBOLS

FLUID TYPES

DESCRIPTION

ENGINE OIL

WARNING: NEW OR USED ENGINE OIL CAN BE IRRITATING TO THE SKIN. AVOID PROLONGED OR REPEATED SKIN CONTACT WITH ENGINE OIL. CONTAMINANTS IN USED ENGINE OIL, CAUSED BY INTERNAL COMBUSTION, CAN BE HAZARDOUS TO YOUR HEALTH. THOROUGHLY WASH EXPOSED SKIN WITH SOAP AND WATER. DO NOT WASH SKIN WITH GASOLINE, DIESEL FUEL, THINNER, OR SOLVENTS, HEALTH PROBLEMS CAN RESULT. DO NOT POLLUTE, DISPOSE OF USED ENGINE OIL PROPERLY. CONTACT YOUR DEALER OR GOVERNMENT AGENCY FOR LOCATION OF COLLECTION CENTER IN YOUR AREA.

When service is required, DaimlerChrysler Corporation recommends that only Mopar® brand parts, lubricants and chemicals be used. Mopar® provides the best engineered products for servicing DaimlerChrysler Corporation vehicles.

Only lubricants bearing designations defined by the following organization should be used.

- Society of Automotive Engineers (SAE)
- American Petroleum Institute (API)
- National Lubricating Grease Institute (NLGI)

FLUID TYPES (Continued)

• Association des Constructeurs Européens d' Automobiles (European Automobile Manufacturers Association) (ACEA)

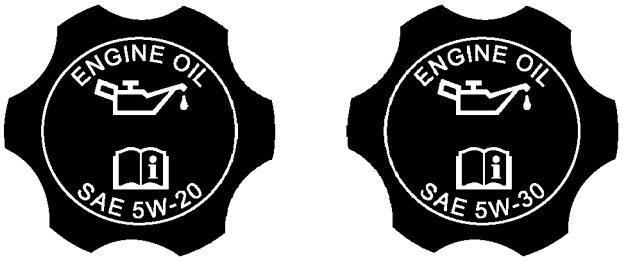
API CERTIFICATION AND LICENSE SYMBOL

9400-9

Fig. 2 API Certification Mark

Use an engine oil that is API Certified (Fig. 2) and Licensed to display the certification mark. MOPAR® provides engine oils that meet or exceed, Material Standard MS-6395 requirement.

SAE VISCOSITY



81364ec7

Fig. 3 5W-30 Oil Filler Cap

SAE 5W-20 and SAE 5W-30 engine oils are recommended for all operating temperatures. These engine oils are designed to improve low temperature starting and vehicle fuel economy. Refer to the engine oil filler cap for the preferred engine oil viscosity grade for each vehicle (Fig. 3). SAE viscosity grades are used to specify the correct viscosity oil for an engine. Use only Multi-Viscosity oils such as SAE 5W-20 or 5W-30. These are specified with a dual SAE viscosity grade which indicates the cold (5W) to hot (20, 30) temperature performance range of the oil.

ACEA CATEGORIES

For countries that use the ACEA European Oil Categories for service fill oils, use engine oils that meet the requirements of ACEA A1/B1, A2/B2, or A3/B3.

CONTAINER IDENTIFICATION

9400-9

Fig. 4 API Certification Mark

The Engine Oil Certification Mark was developed and trademarked by the API to refer customers to those engine oils preferred by the automobile manufacturers. This symbol means that the oil has been certified and licensed by the American Petroleum Institute (API). This certification mark will only be found on the front of the oil containers (Fig. 4). Those oils that do not display the "Mark" on the front of the container should not be used.

DiamlerChrysler only recommends API Certified engine oils that meet the requirements of Material Standard MS-6395. Use Mopar or an equivalent oil meeting the specification MS-6395.

SYNTHETIC ENGINE OILS

There are a number of engine oils being promoted as either synthetic or semi-synthetic. If you chose to use such a product, use **only** those oils that are certified by the American Petroleum Institute (API) to display the "Certification Mark" and show SAE viscosity grade recommended for each vehicle. Follow the service schedule that describes your driving type.

ENGINE OIL ADDITIVES/SUPPLEMENTS

The manufacturer **does not recommend** the addition of any engine oil additives/supplements to the specified engine oil. Engine oil additives/supplements should not be used to enhance engine oil performance. Engine oil additives/supplements should not be used to extend engine oil change intervals. No additive is known to be safe for engine durability and can degrade emission components. Additives can contain undesirable materials that harm the long term durability of engines and emission systems by:

• Increasing the level of Phosphorus and Sulfur in the engine oil. The API Certified Engine Oils control the Phosphorus and Sulfur contents of the oil to levels that reduce the contamination effect on the vehicles emission control system.

• Altering the viscosity characteristics of the engine oil so that it no longer meets the requirements of the specified viscosity grade.

• Creating potential for an undesirable additive compatibility interaction in the engine crankcase.

FLUID TYPES (Continued)

The engine oils contain a performance additive system carefully developed to optimize the oils performance in the engine. The addition of supplements may cause the oil to thicken prematurely, cause excessive deposit build-up and potentially shorten engine life.

ENGINE COOLANT

WARNING: ANTIFREEZE IS AN ETHYLENE GLYCOL BASE COOLANT AND IS HARMFUL IF SWALLOWED OR INHALED. IF SWALLOWED, DRINK TWO GLASSES OF WATER AND INDUCE VOMITING. IF INHALED, MOVE TO FRESH AIR AREA. SEEK MEDICAL ATTENTION IMMEDIATELY. DO NOT STORE IN OPEN OR UNMARKED CONTAINERS. WASH SKIN AND CLOTHING THOROUGHLY AFTER COMING IN CONTACT WITH ETHYLENE GLYCOL. KEEP OUT OF REACH OF CHILDREN. DISPOSE OF GLYCOL BASE COOLANT PROPERLY, CONTACT YOUR DEALER OR GOVERNMENT AGENCY FOR LOCATION OF COLLECTION CENTER IN YOUR AREA. DO NOT OPEN A COOLING SYSTEM WHEN THE ENGINE IS AT OPERATING TEMPERATURE OR HOT UNDER PRESSURE, PERSONAL INJURY CAN RESULT. AVOID RADIATOR COOLING FAN WHEN ENGINE COMPARTMENT RELATED SERVICE IS PERFORMED, PERSONAL INJURY CAN RESULT.

CAUTION: Use of Propylene Glycol based coolants is not recommended, as they provide less freeze protection and less boiling protection.

The cooling system is designed around the coolant. The coolant must accept heat from engine metal, in the cylinder head area near the exhaust valves and engine block. Then coolant carries the heat to the radiator where the tube/fin radiator can transfer the heat to the air.

The use of aluminum cylinder blocks, cylinder heads, and water pumps requires special corrosion protection. Mopar® Antifreeze/Coolant, 5 Year/100,000 Mile Formula (MS-9769), or the equivalent ethylene glycol base coolant with hybrid organic corrosion inhibitors (called HOAT, for Hybrid Organic Additive Technology) is recommended. This coolant offers the best engine cooling without corrosion when mixed with 50% Ethylene Glycol and 50% distilled water to obtain a freeze point of -37°C (-35°F). If it loses color or becomes contaminated, drain, flush, and replace with fresh properly mixed coolant solution.

The green coolant **MUST NOT BE MIXED** with the orange or magenta coolants. When replacing coolant the complete system flush must be performed before using the replacement coolant.

CAUTION: Mopar® Antifreeze/Coolant, 5 Year/100,000 Mile Formula (MS-9769) may not be mixed with any other type of antifreeze. Doing so will reduce the corrosion protection and may result in premature water pump seal failure. If non-HOAT coolant is introduced into the cooling system in an emergency, it should be replaced with the specified coolant as soon as possible.

TRANSMISSION FLUID

NOTE: Refer to the maintenance schedules in the Owner's Manual for the recommended maintenance (fluid/filter change) intervals for this transaxle.

NOTE: All transaxles have a common transmission and differential sump. Filling the transaxle accommodates the differential as well.

TRANSMISSION FLUID

Mopar® ATF+4 (Automatic Transmission Fluid-Type 9602) is required in the 4XTE automatic transaxles. Substitute fluids can induce torque converter clutch shudder.

Mopar® ATF+4 (Automatic Transmission Fluid-Type 9602) when new is red in color. The ATF is dyed red so it can be identified from other fluids used in the vehicle such as engine oil or antifreeze. The red color is not permanent and is not an indicator of fluid condition. As the vehicle is driven, the ATF will begin to look darker in color and may eventually become brown. **This is normal.** A dark brown/black fluid accompanied with a burnt odor and/or deterioration in shift quality may indicate fluid deterioration or transmission component failure.

G288 and T350 Manual transaxles require the use of Mopar® ATF+4 (Automatic Transmission Fluid)

FLUID ADDITIVES

DaimlerChrysler strongly recommends against the addition of any fluids to the transmission, other than those automatic transmission fluids listed above. Exceptions to this policy are the use of special dyes to aid in detecting fluid leaks.

Various "special" additives and supplements exist that claim to improve shift feel and/or quality. These additives and others also claim to improve converter clutch operation and inhibit overheating, oxidation, varnish, and sludge. These claims have not been supported to the satisfaction of DaimlerChrysler and these additives **must not be used.** The use of transmission "sealers" should also be avoided, since they may adversely affect the integrity of transmission seals.

FLUID TYPES (Continued)

FUEL REQUIREMENTS

Your engine is designed to meet all emissions regulations and provide excellent fuel economy and performance when using high quality unleaded gasoline having an octane rating of 87. The use of premium gasoline is not recommended. The use of premium gasoline will provide no benefit over high quality regular gasoline, and in some circumstances may result in poorer performance.

Light spark knock at low engine speeds is not harmful to your engine. However, continued heavy spark knock at high speeds can cause damage and immediate service is required. Engine damage resulting from operation with a heavy spark knock may not be covered by the new vehicle warranty.

Poor quality gasoline can cause problems such as hard starting, stalling and hesitations. If you experience these symptoms, try another brand of gasoline before considering service for the vehicle.

Over 40 auto manufacturers world-wide have issued and endorsed consistent gasoline specifications (the Worldwide Fuel Charter, WWFC) to define fuel properties necessary to deliver enhanced emissions, performance and durability for your vehicle. We recommend the use of gasolines that meet the WWFC specifications if they are available.

REFORMULATED GASOLINE

Many areas of the country require the use of cleaner burning gasoline referred to as “reformulated” gasoline. Reformulated gasoline contain oxygenates, and are specifically blended to reduce vehicle emissions and improve air quality.

We strongly support the use of reformulated gasoline. Properly blended reformulated gasoline will provide excellent performance and durability for the engine and fuel system components.

GASOLINE/OXYGENATE BLENDS

Some fuel suppliers blend unleaded gasoline with oxygenates such as 10% ethanol, MTBE, and ETBE. Oxygenates are required in some areas of the country during the winter months to reduce carbon monoxide emissions. Fuels blended with these oxygenates may be used in your vehicle.

CAUTION: DO NOT use gasoline containing METHANOL. Gasoline containing methanol may damage critical fuel system components.

MMT IN GASOLINE

MMT is a manganese-containing metallic additive that is blended into some gasoline to increase octane. Gasoline blended with MMT provide no performance advantage beyond gasoline of the same octane number without MMT. Gasoline blended with MMT reduce spark plug life and reduce emission system performance in some vehicles. We recommend that gasoline free of MMT be used in your vehicle. The MMT content of gasoline may not be indicated on the gasoline pump; therefore, you should ask your gasoline retailer whether or not his/her gasoline contains MMT.

It is even more important to look for gasoline without MMT in Canada because MMT can be used at levels higher than allowed in the United States. MMT is prohibited in Federal and California reformulated gasoline.

SULFUR IN GASOLINE

If you live in the northeast United States, your vehicle may have been designed to meet California low emission standards with Cleaner-Burning California reformulated gasoline with low sulfur. If such fuels are not available in states adopting California emission standards, your vehicles will operate satisfactorily on fuels meeting federal specifications, but emission control system performance may be adversely affected. Gasoline sold outside of California is permitted to have higher sulfur levels which may affect the performance of the vehicle’s catalytic converter. This may cause the Malfunction Indicator Lamp (MIL), Check Engine or Service Engine Soon light to illuminate. We recommend that you try a different brand of unleaded gasoline having lower sulfur to determine if the problem is fuel related prior to returning your vehicle to an authorized dealer for service.

CAUTION: If the Malfunction Indicator Lamp (MIL), Check Engine or Service Engine Soon light is flashing, immediate service is required; see on-board diagnostics system section.

MATERIALS ADDED TO FUEL

All gasoline sold in the United States and Canada are required to contain effective detergent additives. Use of additional detergents or other additives is not needed under normal conditions.

FUEL SYSTEM CAUTIONS

CAUTION: Follow these guidelines to maintain your vehicle’s performance:

- The use of leaded gas is prohibited by Federal law. Using leaded gasoline can impair engine performance, damage the emission control system, and could result in loss of warranty coverage.
- An out-of-tune engine, or certain fuel or ignition malfunctions, can cause the catalytic converter to

FLUID TYPES (Continued)

overheat. If you notice a pungent burning odor or some light smoke, your engine may be out of tune or malfunctioning and may require immediate service. Contact your dealer for service assistance.

- When pulling a heavy load or driving a fully loaded vehicle when the humidity is low and the temperature is high, use a premium unleaded fuel to help prevent spark knock. If spark knock persists, lighten the load, or engine piston damage may result.
- The use of fuel additives which are now being sold as octane enhancers is not recommended. Most of these products contain high concentrations of methanol. Fuel system damage or vehicle performance problems resulting from the use of such fuels or additives is not the responsibility of DaimlerChrysler Corporation and may not be covered under the new vehicle warranty.

NOTE: Intentional tampering with emissions control systems can result in civil penalties being assessed against you.

BRAKE FLUID

The brake fluid used in this vehicle must conform to DOT 3 specifications and SAE J1703 standards. No other type of brake fluid is recommended or approved for usage in the vehicle brake system. Use only Mopar® Brake Fluid or equivalent from a tightly sealed container.

CAUTION: Never use reclaimed brake fluid or fluid from an container which has been left open. An open container of brake fluid will absorb moisture from the air and contaminate the fluid.

CAUTION: Never use any type of a petroleum-based fluid in the brake hydraulic system. Use of such type fluids will result in seal damage of the vehicle brake hydraulic system causing a failure of the vehicle brake system. Petroleum based fluids would be items such as engine oil, transmission fluid, power steering fluid, etc.

POWER STEERING FLUID

The recommended fluid for the power steering system is Mopar® ATF+4 Automatic Transmission Fluid (MS-9602).

Mopar® ATF+4, when new, is red in color. ATF+4 is dyed red so it can be identified from other fluids used in the vehicle such as engine oil or antifreeze. The red color is not permanent and is not an indicator of fluid condition. As the vehicle is driven, ATF+4 will begin to look darker in color and may eventually become brown. **THIS IS NORMAL.** ATF+4 also has a unique odor that may change with age. Consequently, odor and color cannot be used to indicate the fluid condition or the need for a fluid change.

FLUID CAPACITIES

SPECIFICATIONS - FLUID CAPACITIES

DESCRIPTION	SPECIFICATION
Fuel Tank	57L (15 gal.)
Engine Oil* - 1.6L	4.3L (4.5 qts.)
Engine Oil* - 2.0L	4.3L (4.5 qts.)
Engine Oil* - 2.2L Diesel	7.0L (7.4 qts.)
Engine Oil* - 2.4L	4.8L (5.0 qts.)
Cooling System** - 1.6L, 2.0L, and 2.4L	6.2L (6.5 qts.)
Cooling System** - 2.2L Diesel	9.0L (9.5 qts.)
Automatic Transaxle - Estimated Service Fill	3.8L (4.0 qts.)
Automatic Transaxle - Overhaul Fill Capacity with Torque Converter Empty	8.1L (8.6 qts.)
Manual Transaxle - NV T350	2.4 - 2.7L (2.5 - 2.8 qts.)
Manual Transaxle - Getrag 288	2.2L Turbo Diesel: 2.0L (2.1 qts.)
	2.4L Turbo: 1.8L (1.9 qts.)
*(includes new filter)	
**(Includes heater and coolant recovery bottle filled to MAX level.)	

FLUID FILL/CHECK LOCATIONS

DESCRIPTION

The fluid check/fill point locations are located in each applicable service manual section.

LUBRICATION POINTS

DESCRIPTION

Lubrication point locations are located in each applicable Sections.

MAINTENANCE SCHEDULES

DESCRIPTION

MAINTENANCE SCHEDULE

There are three maintenance schedules that show **required** service for your vehicle.

First is Schedule **"B"- ALL ENGINES**. It is for vehicles that are operated under the conditions that are listed below and at the beginning of the schedule.

- Day and night temperatures are below 32° F (0° C).
- Stop and go driving.
- Extensive engine idling.
- Driving in dusty conditions.
- Short trips of less than 10 miles (16 km).
- More than 50% of your driving is at sustained high speeds during hot weather, above 90° F (32° C).
- Trailer towing.†◊
- Taxi, police, or delivery service (commercial service).†◊
- Off-road or desert operation.
- **If equipped for and operating with E-85 (ethanol) fuel.**

NOTE: If ANY of these apply to you then change your engine oil every 3,000 miles (5 000 km) and follow schedule "B - All Engines" of the ″Maintenance Schedules″ section of this manual.

NOTE: IF ANY of these apply to you then flush and replace the engine coolant every 102,000 miles (164,000 km) or 60 months, whichever comes first, and follow schedule "B—All Engines" of the ″Maintenance Schedules″ section of this manual.

NOTE: Most vehicles are operated under the conditions listed for Schedule ″B″ - ALL ENGINES.

Second is Schedule **"A"—NON TURBO**. It is for vehicles that are not operated under any of the conditions listed under Schedule ″B″—ALL ENGINES.

Third is Schedule **"A"—TURBO**. It is for vehicles that are not operated under any of the conditions listed under Schedule ″B″—ALL ENGINES.

Use the schedule that best describes your driving conditions. Where time and mileage are listed, follow the interval that occurs first.

CAUTION: Failure to perform the required maintenance items may result in damage to the vehicle.

At Each Stop for Fuel

- Check the engine oil level about 5 minutes after a fully warmed engine is shut off. Checking the oil level while the vehicle is on level ground will improve the accuracy of the oil level reading. Add oil only when the level is at or below the ADD or MIN mark.
- Check the windshield washer solvent and add if required.

Once a Month

- Check tire pressure and look for unusual wear or damage.
- Inspect the battery and clean and tighten the terminals as required.
- Check the fluid levels of coolant reservoir, brake master cylinder and transaxle and add as needed.
- Check all lights and all other electrical items for correct operation.
- Check rubber seals on each side of the radiator for proper fit.

At Each Oil Change

- Change the engine oil filter.
- Inspect the exhaust system.
- Inspect the brake hoses.
- Inspect the CV joints and front suspension components.
- Check the automatic transaxle fluid level.
- Check the manual transaxle fluid level and fill plug condition.
- Check the coolant level, hoses, and clamps.

SCHEDULE B - ALL ENGINES

Follow schedule "B" - All Engines if you usually operate your vehicle under one or more of the following conditions.

Change the automatic transmission fluid and filter every 60,000 miles (96 000 km) if the vehicle is usually operated under one or more of the conditions marked with an ◊.

Change the manual transaxle fluid every 48,000 miles (77 000 km) if the vehicle is usually operated under one or more of the conditions marked with an †.

- Day and night temperatures are below 32° F (0° C).
- Stop and go driving.
- Extensive engine idling.
- Driving in dusty conditions.
- Short trips of less than 10 miles (16.2 km).
- More than 50% of your driving is at sustained high speeds during hot weather, above 90° F (32° C).
- Trailer towing.†◊
- Taxi, police, or delivery service (commercial service).†◊

MAINTENANCE SCHEDULES (Continued)

- Off-road or desert operation.
- **If equipped for and operating with E-85 (ethanol) fuel.**

NOTE: If ANY of these apply to you then change your engine oil every 3,000 miles (5 000 km) and follow schedule "B - All Engines" of the "Maintenance Schedules" section of this manual.

NOTE: IF ANY of these apply to you then flush and replace the engine coolant every 102,000 miles (164,000 km) or 60 months, whichever comes first, and follow schedule "B—All Engines" of the "Maintenance Schedules" section of this manual.

If none of these apply to you, and your vehicle is equipped with a Non–Turbo Charged Engine then change your engine oil at every interval shown on schedule "A"—NON TURBO in the maintenance schedule section of this manual.

If none of these apply to you, and your vehicle is equipped with a Turbo Charged Engine change your engine oil at every interval shown on schedule "A"—TURBO in the maintenance schedule section of this manual.

Miles (Kilometers)	**3,000 (5 000)**	**6,000 (10 000)**	**9,000 (14 000)**	**12,000 (19 000)**	**15,000 (24 000)**	**18,000 (29 000)**

* This maintenance is recommended by the manufacturer to the owner but is not required to maintain the emissions warranty.

‡ This maintenance is not required if previously replaced.

Inspection and service should also be performed anytime a malfunction is observed or suspected. Retain all receipts.

WARNING: You can be badly injured working on or around a motor vehicle. Do only that service work for which you have the knowledge and the right equipment. If you have any doubt about your ability to perform a service job, take your vehicle to a competent mechanic.

MAINTENANCE SCHEDULES - GASOLINE ENGINES - EXPORT

There are three maintenance schedules that show **required** service for your vehicle.

First is **SCHEDULE A - NON TURBO-CHARGED ENGINES**. It is for vehicles that are not operated under any of the conditions listed under SCHEDULE B - ALL ENGINES.

Second is **SCHEDULE A - 2.4L TURBO-CHARGED ENGINES**. It is for vehicles that are not operated under any of the conditions listed under SCHEDULE B - ALL ENGINES.

Third is **SCHEDULE B - ALL ENGINES**. It is for vehicles that are operated under the conditions that are listed below and at the beginning of the schedule.

- Day and night temperatures are below 0° C (32° F).
- Stop and go driving.
- Extensive engine idling.
- Driving in dusty conditions.
- Short trips of less than 16 km (10 miles).
- More than 50% of your driving is at sustained high speeds during hot weather, above32° C (90° F).
- Trailer towing.†◊
- Taxi, police, or delivery service (commercial service).†◊
- Off-road or desert operation.
- **If equipped for and operating with E-85 (ethanol) fuel.**

NOTE: If ANY of these apply to you then change your engine oil every 5 000 km (3,000 miles) or 3 months, whichever comes first and follow SCHEDULE "B"—ALL ENGINES of the "Maintenance Schedules" section of this manual.

NOTE: IF ANY of these apply to you then flush and replace the engine coolant every 164,000 km (102,000 miles) or 60 months, whichever comes first, and follow SCHEDULE "B"—ALL ENGINES of the "Maintenance Schedules" section of this manual.

NOTE: Most vehicles are operated under the conditions listed for SCHEDULE "B"—ALL ENGINES.

If none of these apply to you, and your vehicle is equipped with a Non–Turbo Charged Engine then change your engine oil at every interval shown on schedule "A"—NON TURBO in the maintenance schedule section of this manual.

If none of these apply to you, and your vehicle is equipped with a Turbo Charged Engine change your engine oil at every interval shown on schedule "A"—TURBO in the maintenance schedule section of this manual.

Use the schedule that best describes your driving conditions. Where time and mileage are listed, follow the interval that occurs first.

CAUTION: Failure to perform the required maintenance items may result in damage to the vehicle.

At Each Stop for Fuel

- Check the engine oil level about 5 minutes after a fully warmed engine is shut off. Checking the oil level while the vehicle is on level ground will improve the accuracy of the oil level reading. Add oil only when the level is at or below the ADD or MIN mark.

MAINTENANCE SCHEDULES (Continued)

- Check the windshield washer solvent and add if required.

Once a Month

- Check tire pressure and look for unusual wear or damage.
- Inspect the battery and clean and tighten the terminals as required.
- Check the fluid levels of coolant reservoir, brake master cylinder, add as needed.
- Check all lights and all other electrical items for correct operation.
- Check rubber seals on each side of the radiator for proper fit.

At Each Oil Change

- Change the engine oil filter.
- Inspect the exhaust system.
- Inspect the brake hoses.
- Inspect the CV joints and front suspension components.
- Check the automatic transaxle fluid level.
- Check the manual transaxle fluid level and fill plug condition.
- Check the coolant level, hoses, and clamps.

SCHEDULE A - NON TURBOCHARGED ENGINES

Kilometers (Miles) [Months]	**12 000 (7,500) [6]**	**24 000 (15,000) [12]**	**36 000 (22,500) [18]**	**48 000 (30,000) [24]**	**60 000 (37,500) [30]**

Adjust the generator drive belt, 2.4L engines only.			X		
Flush and replace the engine coolant, at 60 months, if not replaced at 160 000 km.					X
Replace the **make-up filter.**			X		
Replace the **spark plugs and ignition cables.**			X		
Inspect tie rod end boot seals.			X		
Replace the air conditioning air filter.	X		X		X

MAINTENANCE SCHEDULES (Continued)

Kilometers **(Miles)** **[Months]**	**132 000** **(82,500)** **[66]**	**144 000** **(90,000)** **[72]**	**156 000** **(97,500)** **[78]**	**160 000** **(100,000)**	**168 000** **(105,000)** **[84]**
Change engine oil and engine oil filter.	X	X	X		X
Rotate tires.	X	X	X		X
Inspect the brake linings.		X			
Replace **air cleaner element filter.**		X			
Inspect the **PCV valve** and replace if necessary. * ‡		X			
Replace the **make-up filter** (located inside the air cleaner).		X			
Inspect tie rod end boot seals.		X			
Adjust the generator drive belt tension, 2.4L engines only.		X			
Replace the **spark plugs**.		X			
Flush and replace engine coolant, if it not replaced at 60 months.				X	
Replace the air conditioning air filter.		X			X

Kilometers **(Miles)** **[Months]**	**180 000** **(112,500)** **[90]**	**192 000** **(120,000)** **[96]**
Change engine oil and engine oil filter.	X	X
Rotate tires.	X	X
Inspect the brake linings.		X
Inspect the **PCV valve** and replace as necessary. * ‡		X
Inspect tie rod end boot seals.		X
Adjust the generator drive belt tension, 2.4L engines only.		X
Replace the **air cleaner filter.**		X
Replace the **spark plugs and ignition cables.**		X
Replace the **make-up air filter.**		X
Flush and replace the engine coolant, if not replaced at 160 000 km.		X
Replace air conditioning air filter.		X
Replace the **engine timing belt.**		X

NOTE: Under NO circumstances should the engine oil change interval exceed 12 000 km (7,500 miles) or 6 months, whichever come first.

* This maintenance is recommended bythe manufacturer to the owner but is not required to maintain the emissions warranty.

‡ This maintenance is not required if previously replaced.

Inspection and service should also be performed anytime a malfunction is observed or suspected. Retain all receipts.

MAINTENANCE SCHEDULES (Continued)

SCHEDULE A - 2.4L TURBOCHARGED ENGINES

NOTE: An initial engine oil and filter change at 8 000 km (5,000 miles) is required by the manufacturer. All other engine oil and filter changes should be done every 12 000 km (7,500 miles) thereafter.

Kilometers (Miles) [Months]	**8 000 (5,000) [6]**	**20 000 (12,500) [12]**	**32 000 (20,000) [18]**	**44 000 (27,500) [24]**	**56 000 (35,500) [30]**
Change engine oil and engine oil filter.	X	X	X	X	X

‡ This maintenance is not required if previously replaced.

Inspection and service should also be performed anytime a malfunction is observed or suspected. Retain all receipts.

MAINTENANCE SCHEDULES (Continued)

SCHEDULE B - ALL ENGINES

Follow schedule "B" if you usually operate your vehicle under one or more of the following conditions. Change the automatic transmission fluid and filter every 96 000 km (60,000 miles) if the vehicle is usually operated under one or more of the conditions marked with an ◊.

Change the manual transaxle fluid every 77 000 km (48,000 miles) if the vehicle is usually operated under one or more of the conditions marked with an †.

- Day and night temperatures are below 0° C (32° F).
- Stop and go driving.
- Extensive engine idling.
- Driving in dusty conditions.
- Short trips of less than 16.2 km (10 miles).
- More than 50% of your driving is at sustained high speeds during hot weather, above 32° C (90° F).
- Trailer towing.† ◊
- Taxi, police, or delivery service (commercial service).† ◊
- Off-road or desert operation.
- **If equipped for and operating with E-85 (ethanol) fuel.**

Kilometers (Miles)	**5 000 (3,000)**	**10 000 (6,000)**	**14 000 (9,000)**	**19 000 (12,000)**	**24 000 (15,000)**
Change engine oil and engine oil filter, if not replaced at 3 months.	X	X	X	X	X
Rotate tires.		X		X	
Inspect the brake linings.			X		
Inspect and replace, if required, the **make-up air filter.**					X
Inspect the **engine air cleaner filter**, replace as necessary. *					X
Replace the air conditioning air filter.					X

Kilometers (Miles)	**29 000 (18,000)**	**34 000 (21,000)**	**38 000 (24,000)**	**43 000 (27,000)**	**48 000 (30,000)**
Change engine oil and engine oil filter, if not replaced at 3 months.	X	X	X	X	X
Rotate tires.	X		X		X
Inspect the brake linings.	X			X	
Replace the **engine air cleaner filter.**					X
Inspect the **PCV valve** and replace, if necessary. *					X
Adjust the generator drive belt tension, 2.4L engines only.					X
Replace the **make-up air filter.**					X
Replace the **spark plugs**.					X
Inspect the tie rod ends and boot seal.					X
Replace the air conditioning air filter.					X

MAINTENANCE SCHEDULES (Continued)

Kilometers **(Miles)**	**53 000** **(33,000)**	**58 000** **(36,000)**	**62 000** **(39,000)**	**67 000** **(42,000)**	**72 000** **(45,000)**
Change engine oil and engine oil filter, if not replaced at 3 months.	X	X	X	X	X
Rotate tires.		X		X

Rotate tires.	X		X		X
Inspect the brake linings.			X		
Replace the **engine air cleaner filter.**					X
Inspect the **PCV valve** and replace, if necessary. * ‡					X
Change the automatic transaxle fluid and filter. ◊					X
Change the manual transaxle fluid.†	X				
Change the brake fluid. If your vehicle is used for trailer towing.	X				
Inspect the tie rod ends and boot seals.					X
Adjust the generator drive belt tension, 2.4L engines only.					X
Replace the **make-up air filter.**					X
Replace the **spark plugs and ignition cables.**					X
Replacer the air conditioning air filter.					X
Flush and replace the engine coolant, at 60 months, if not done 163 000 km.					X

Kilometers **(Miles)**	**101 000** **(63,000)**	**106 000** **(66,000)**	**110 000** **(69,000)**	**115 000** **(72,000)**	**120 000** **(75,000)**
Change engine oil and engine oil filter, if not replaced at 3 months.	X	X	X	X	X
Rotate tires.		X		X	
Inspect the brake linings.	X			X	
Inspect the **engine air cleaner filter.** and replace, if necessary. *					X
Inspect the **make-up air filter,** and replace as necessary.	X				
Replace the air conditioning filter.					X

MAINTENANCE SCHEDULES (Continued)

Kilometers (Miles)	**125 000 (78,000)**	**130 000 (81,000)**	**134 000 (84,000)**	**139 000 (87,000)**	**144 000 (90,000)**
Change engine oil and engine oil filter, if not replaced at 3 months.	X	X	X	X	X
Rotate tires.	X		X		X
Inspect the brake linings.		X			X
Replace the **engine air cleaner filter.**					X
Inspect the **PCV valve** and replace, if necessary. Not required if previously changed. * ‡					X
Inspect the tie rod ends and boot seals.					X
Adjust the generator drive belt tension, 2.4L engines only.					X
Replace the **make-up air filter.**					X
Replace the **spark plugs**.					X
Replace **engine timing belt.**					X
Replace the air conditioning air filter.					X

Kilometers (Miles)	**149 000 (93,000)**	**154 000 (96,000)**	**158 000 (99,000)**	**164 000 (102,000)**	**168 000 (105,000)**
Change engine oil and engine oil filter, if not replaced at 3 months.	X	X	X	X	X
Rotate tires.		X		X	
Inspect the brake linings.			X		
Inspect the **engine air cleaner filter** and replace as necessary. *					X
Change the manual Transaxle Fluid.†		X			
Flush and replace the engine coolant, if not done at 60 months.				X	
Change the brake fluid. If your vehicle is used for trailer towing.		X			
Inspect the **make-up air filter,** and replace as necessary.					X
Replace the air conditioning air filter.					X

MAINTENANCE SCHEDULES (Continued)

Kilometers (Miles)	173 000 (108,000)	178 000 (111,000)	182 000 (114,000)	187 000 (117,000)	192 000 (120,000)
Change engine oil and engine oil filter, if not replaced at 3 months.	X	X	X	X	X
Rotate tires.	X		X		X
Inspect the brake linings.		X			X
Inspect the **PCV valve** and replace, if necessary. Not required if previously changed. * ‡					X
Inspect the tie rod ends and boot seals.					X
Adjust the generator drive belt tension, 2.4L engines only.					X
Replace the air conditioning air filter.					X
Change automatic transaxle fluid and filter. ◊					X
Replace the **make-up air filter.**					X
Replace the **engine air cleaner filter.**					X
Flush and replace the engine coolant at 120 months, if not replaced at 163 000 km.					X
Replace the **spark plugs and ignition cables.**					X

* This maintenance is recommended by the manufacturer to the owner but is not required to maintain the emissions warranty.

‡ This maintenance is not required if previously replaced.

† This maintenance is required only for police, taxi, limousine type operation, or trailer towing.

◊ This maintenance is required only for police, taxi, limousine type operation, or trailer towing.

Inspection and service should also be performed anytime a malfunction is observed or suspected. Retain all receipts.

WARNING: You can be badly injured working on or around a motor vehicle. Do only that service work for which you have the knowledge and the right equipment. If you have any doubt about your ability to perform a service job, take your vehicle to a competent mechanic.

MAINTENANCE SCHEDULE - DIESEL ENGINES - EXPORT

There are two maintenance schedules that show the **required** service for your vehicle.

First is Schedule **"A"**. It is for vehicles that are not operated under any of the conditions listed under Schedule ″B″.

NOTE: Most vehicles are operated under the conditions listed for Schedule ″B″.

Second is Schedule **"B"**. It is for vehicles that are operated under the conditions that are listed below and at the beginning of the schedule.

- Extensive engine idling.
- Driving in dusty conditions.
- More than 50% of your driving is at sustained high speeds during hot weather, above 32° C (90° F).
- Trailer towing.
- Taxi, police, or delivery service (commercial service).

Use the schedule that best describes your driving conditions. Where time and mileage are listed, follow the interval that occurs first.

CAUTION: Failure to perform the required maintenance items may result in damage to the vehicle.

At Each Stop for Fuel

- Check the engine oil level, add as required.
- Check the windshield washer solvent and add if required.

MAINTENANCE SCHEDULES (Continued)

Once a Month

- Check the tire pressure and look for unusual wear or damage.
- Inspect the battery and clean and tighten the terminals as required.
- Check the fluid levels of coolant reservoir, brake master cylinder, power steering and transaxle and add as needed.
- Check all lights and all other electrical items for correct operation.

At Each Oil Change

- Replace the engine oil filter at each oil change.
- Inspect the exhaust system.
- Inspect brake linings, hoses and calipers.
- Inspect the CV joints and front suspension components.
- Check the coolant level, hoses, and clamps.
- Inspect engine accessory drive belts.

SCHEDULE A

Kilometers	20 000 km	40 000 km	60 000 km	80 000 km	100 000 km
Change engine oil and engine oil filter.	X	X	X	X	X
Rotate tires.	X	X	X	X	X
Inspect engine air filter element. Replace as necessary.	X		X		X
Replace engine air filter element		X		X	
Replace fuel filter.	X	X	X	X	X
Inspect the brake linings.	X	X	X	X	X
Inspect tie rod ends and boot seals.		X		X	
Replace air conditioning air filter.	X	X	X	X	X

Kilometers	120 000 km	140 000 km	160 000 km	180 000 km
Change engine oil and engine oil filter.	X	X	X	X
Rotate tires.	X	X	X	X
Inspect engine air filter element. Replace as necessary.		X		X
Replace engine air filter element	X		X	
Replace fuel filter.	X	X	X	X
Flush and refill engine coolant system.			X	
Inspect the brake linings.	X	X	X	X
Inspect tie rod ends and boot seals.	X		X	
Replace air conditioning air filter.	X	X	X	X

Inspection and service should also be performed anytime a malfunction is observed or suspected. Retain all receipts.

MAINTENANCE SCHEDULES (Continued)

SCHEDULE B

Follow schedule "B" if you usually operate your vehicle under one or more of the following conditions.

- Extensive engine idling.
- Driving in dusty conditions.
- More than 50% of your driving is at sustained high speeds during hot weather, above 32° C (90° F).
- Trailer towing.
- Taxi, police, or delivery service (commercial service).

Kilometers	10 000 km	20 000 km	30 000 km	40 000 km	50 000 km
Change engine oil and engine oil filter.	X	X	X	X	X
Rotate tires.		X		X	
Inspect engine air filter element. Replace as necessary.	X		X		X
Replace engine air filter element		X		X	
Replace fuel filter.		X		X	
Inspect the brake linings.	X	X	X	X	X
Inspect tie rod ends and boot seals.				X	
Replace air conditioning air filter.		X		X	

Kilometers	60 000 km	70 000 km	80 000 km	90 000 km	100 000 km
Change engine oil and engine oil filter.	X	X	X	X	X
Rotate tires.	X		X		X
Inspect engine air filter element. Replace as necessary.		X		X	
Replace engine air filter element	X		X		X
Replace fuel filter.	X		X		X
Change the manual transaxle fluid.			X		
Change the brake fluid.			X		
Inspect the brake linings.	X	X	X	X	X
Inspect tie rod ends and boot seals.			X		
Replace air conditioning air filter.	X		X		X

Kilometers	110000 km	120 000 km	130000 km	140000 km	150000 km	160000 km
Change engine oil and engine oil filter.	X	X	X	X	X	X
Rotate tires.		X		X		X
Inspect engine air filter element. Replace as necessary.	X		X		X	
Replace engine air filter element		X		X		X
Replace fuel filter.	X		X		X	
Flush and refill engine coolant system.						X
Change the manual transaxle fluid.						X
Change the brake fluid.						X
Inspect the brake linings.	X	X	X	X	X	X
Inspect tie rod ends and boot seals.		X				X
Replace air conditioning air filter.		X		X		X

MAINTENANCE SCHEDULES (Continued)

Inspection and service should also be performed anytime a malfunction is observed or suspected. Retain all receipts.

WARNING: You can be badly injured working on or around a motor vehicle. Do only that service work for which you have the knowledge and the right equipment. If you have any doubt about your ability to perform a service job, take your vehicle to a competent mechanic.

HOISTING

STANDARD PROCEDURE - HOISTING

Refer to Owner's Manual provided with vehicle for proper emergency jacking procedures.

WARNING: THE HOISTING AND JACK LIFTING POINTS PROVIDED ARE FOR A COMPLETE VEHICLE. WHEN THE ENGINE OR REAR SUSPENSION IS REMOVED FROM A VEHICLE, THE CENTER OF GRAVITY IS ALTERED MAKING SOME HOISTING CONDITIONS UNSTABLE. PROPERLY SUPPORT OR SECURE VEHICLE TO HOISTING DEVICE WHEN THESE CONDITIONS EXIST.

CAUTION: Do not position hoisting device on suspension components, damage to vehicle can result. Do not attempt to raise one entire side of the vehicle by placing a floor jack midway between the front and rear wheels. This practice may result in permanent damage to the body.

When properly positioned, a floor jack can be used to lift the vehicle and support the raised vehicle with jack stands (Fig. 5).

A floor jack or any lifting device, must never be used on any part of the underbody other then the described areas.

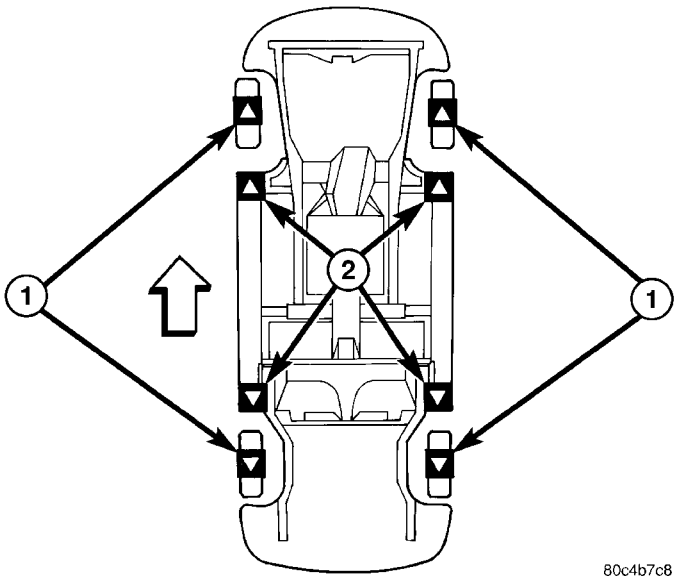

Fig. 5 Hoisting and Jacking Points

1 - DRIVE ON LIFT
2 - FRAME CONTACT LIFT (SINGLE POST)
2 - CHASSIS LIFT (DUAL POST)
2 - OUTBOARD LIFT (DUAL LIFT)
2 - FLOOR JACK

JUMP STARTING

STANDARD PROCEDURE - JUMP STARTING

WARNING: REVIEW ALL SAFETY PRECAUTIONS AND WARNINGS IN BATTERY/STARTING/CHARGING SECTIONS. DO NOT JUMP START A FROZEN BATTERY, PERSONAL INJURY CAN RESULT. DO NOT JUMP START WHEN MAINTENANCE FREE BATTERY INDICATOR DOT IS YELLOW OR BRIGHT COLOR. DO NOT JUMP START A VEHICLE WHEN THE BATTERY FLUID IS BELOW THE TOP OF LEAD PLATES. DO NOT ALLOW JUMPER CABLE CLAMPS TO TOUCH EACH OTHER WHEN CONNECTED TO A BOOSTER SOURCE. DO NOT USE OPEN FLAME NEAR BATTERY. REMOVE METALLIC JEWELRY WORN ON HANDS OR WRISTS TO AVOID INJURY BY ACCIDENTAL ARCING OF BATTERY CURRENT. WHEN USING A HIGH OUTPUT BOOSTING DEVICE, DO NOT ALLOW BATTERY VOLTAGE TO EXCEED 16 VOLTS. REFER TO INSTRUCTIONS PROVIDED WITH DEVICE BEING USED.

CAUTION: When using another vehicle as a booster, do not allow vehicles to touch. Electrical systems can be damaged on either vehicle.

JUMP STARTING (Continued)

TO JUMP START A DISABLED VEHICLE:

(1) Raise hood on disabled vehicle and visually inspect engine compartment for:

- Battery cable clamp condition, clean if necessary.
- Frozen battery.
- Yellow or white color test indicator, if equipped.
- Generator drive belt condition and tension.
- Fuel fumes or leakage, correct if necessary.

CAUTION: If the cause of starting problem on disabled vehicle is severe, damage to booster vehicle charging system can result.

(2) When using another vehicle as a booster source, park the booster vehicle within cable reach. Turn off all accessories, set the parking brake, place the automatic transmission in PARK or the manual transmission in NEUTRAL and turn the ignition OFF.

(3) On disabled vehicle, place gear selector in park or neutral and set park brake. Turn off all accessories.

(4) Connect jumper cables to booster battery. RED clamp to positive terminal (+) or remote terminal. BLACK clamp to negative terminal (-). DO NOT allow clamps at opposite end of cables to touch, electrical arc will result. Review all warnings in this procedure.

(5) On disabled vehicle connect RED jumper cable clamp to positive (+) remote terminal. (Fig. 6). Connect BLACK jumper cable clamp to engine ground.

(a) Pull the protective sleeve from the remote positive terminal labeled Position Jump Post Attachment.

(b) Connect RED jumper cable clamp to positive (+) remote terminal (Fig. 6).

(c) Connect BLACK jumper cable clamp to Negative Jump Post Attachment or engine ground as close to the ground cable attaching point as possible

(6) Start the engine in the vehicle which has the booster battery, let the engine idle a few minutes, then start the engine in the vehicle with the discharged battery.

CAUTION: Do not crank starter motor on disabled vehicle for more than 15 seconds, starter will overheat and could fail.

(7) Allow battery in disabled vehicle to charge to at least 12.4 volts (75% charge) before attempting to start engine. If engine does not start within 15 seconds, stop cranking engine and allow starter to cool (15 minutes), before cranking again.

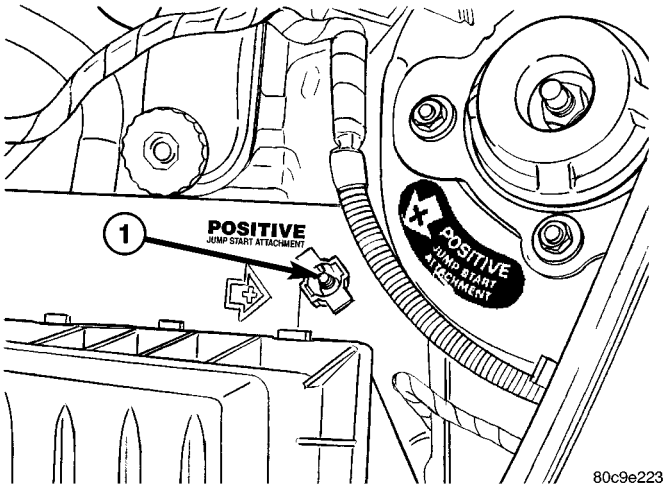

Fig. 6 POSITIVE JUMPER CABLE CLAMP CONNECTION

1 - BATTERY POSITIVE REMOTE TERMINAL

DISCONNECT CABLE CLAMPS AS FOLLOWS:

- Disconnect BLACK cable clamp from engine ground on disabled vehicle.
- Disconnect RED cable clamp from battery positive remote terminal.

TOWING

STANDARD PROCEDURE - TOWING

WARNING: DO NOT ALLOW TOWING ATTACHMENT DEVICES TO CONTACT THE FUEL TANK OR LINES, FUEL LEAK CAN RESULT. DO NOT LIFT OR TOW VEHICLE BY FRONT OR REAR BUMPER, OR BUMPER ENERGY ABSORBER UNITS. DO NOT VENTURE UNDER A LIFTED VEHICLE IF NOT SUPPORTED PROPERLY ON SAFETY STANDS. DO NOT ALLOW PASSENGERS TO RIDE IN A TOWED VEHICLE. USE A SAFETY CHAIN THAT IS INDEPENDENT FROM THE TOWING ATTACHMENT DEVICE.

CAUTION: Do not damage brake lines, exhaust system, shock absorbers, sway bars, or any other under vehicle components when attaching towing device to vehicle. Do not attach towing device to front or rear suspension components. Do not secure vehicle to towing device by the use of front or rear suspension or steering components. Remove or secure loose or protruding objects from a damaged vehicle before towing. Refer to state and local rules and regulations before towing a vehicle. Do not allow weight of towed vehicle to bear on lower fascia, air dams, or spoilers.

TOWING (Continued)

To avoid damage to bumper fascia and air dams use of a wheel lift or flat bed towing device (Fig. 7) is recommended. When using a wheel lift towing device, be sure the unlifted end of disabled vehicle has at least 100 mm (4 in.) ground clearance. If minimum ground clearance cannot be reached, use a towing dolly. If a flat bed device is used, the approach angle should not exceed 15 degrees.

FRONT SUSPENSION

DESCRIPTION - FRONT SUSPENSION

This vehicle has a gas pressurized MacPherson strut type front suspension design (Fig. 1).

The front suspension consists of these major components:

- Hub (pressed into bearing)
- Bearing (pressed into steering knuckle)
- Lower control arm (2)
- Stabilizer bar
- Steering knuckle (2)
- Strut assembly (2)

Refer to individual components for additional information.

OPERATION - FRONT SUSPENSION

The front suspension allows each front wheel on a vehicle to adapt to different road surfaces and conditions without greatly affecting the opposite wheel and the ability to control the vehicle. Each side of the front suspension is allowed to pivot so the vehicle can be steered in the direction preferred.

When a vehicle strikes a bump, the force is transferred through the hub, bearing, and knuckle, into the strut assembly to absorb the force and dampen it. During steering maneuvers, the strut assembly (through a pivot bearing in the upper strut mount) and steering knuckle (through the lower ball joint mounted on the lower control arm) turn as an assembly.

WARNING

WARNINGS AND CAUTIONS

WARNING: DUST AND DIRT ACCUMULATING ON BRAKE PARTS DURING NORMAL USE MAY CONTAIN ASBESTOS FIBERS FROM PRODUCTION OR AFTERMARKET LININGS. BREATHING EXCESSIVE CONCENTRATIONS OF ASBESTOS FIBERS CAN CAUSE SERIOUS BODILY HARM. EXERCISE CARE WHEN SERVICING BRAKE PARTS. DO NOT SAND, OR GRIND BRAKE LINING UNLESS EQUIPMENT USED IS DESIGNED TO CONTAIN THE DUST RESIDUE. DO NOT CLEAN BRAKE PARTS WITH COMPRESSED AIR OR BY DRY BRUSHING. CLEANING SHOULD BE DONE BY DAMPENING THE BRAKE COMPONENTS WITH A FINE MIST OF WATER, THEN WIPING THE BRAKE COMPONENTS CLEAN WITH A DAMPENED CLOTH. DISPOSE OF CLOTH AND ALL RESIDUE CONTAINING ASBESTOS FIBERS IN AN IMPERMEABLE CONTAINER WITH THE APPROPRIATE LABEL. FOLLOW PRACTICES PRESCRIBED BY THE OCCUPATIONAL SAFETY AND HEALTH ADMINISTRATION (OSHA) AND THE ENVIRONMENTAL PROTECTION AGENCY (EPA) FOR THE HANDLING, PROCESSING, AND DISPOSITION OF DUST OR DEBRIS THAT MAY CONTAIN ASBESTOS FIBERS.

WARNING: DO NOT REMOVE THE STRUT SHAFT NUT WHILE STRUT ASSEMBLY IS INSTALLED IN VEHICLE, OR BEFORE THE COIL SPRING IS COMPRESSED WITH A COMPRESSION TOOL. THE SPRING IS HELD UNDER HIGH PRESSURE.

CAUTION: Only frame contact hoisting equipment can be used on this vehicle. It cannot be hoisted using equipment designed to lift a vehicle by the rear axle. If this type of hoisting equipment is used, damage to rear suspension components will occur.

CAUTION: At no time when servicing a vehicle can a sheet metal screw, bolt, or other metal fastener be installed in the shock tower to take the place of an original plastic clip. It may come into contact with the strut or coil spring.

CAUTION: Wheel bearing damage will result if after loosening the hub nut, the vehicle is rolled on the ground or the weight of the vehicle is allowed to be supported by the tires for a length of time.

STANDARD PROCEDURE - LUBRICATION

There are no serviceable lubrication points on the front suspension. The front lower ball joints have grease fittings which have had the head snapped off by the manufacturer after they have been filled. This has been done to eliminate the possibility of damaging the non-vented seals. Grease will not leak from the broken grease fittings. The ball joints are sealed for life and require no maintenance.

CAUTION: No attempt should be made to replace the ball joint grease fitting with a new fitting, then filling the ball joint with grease. Damage to the grease seal can result.

HUB / BEARING

DESCRIPTION

The wheel bearing and hub are pressed into the steering knuckle. (Refer to 2 - SUSPENSION/ FRONT/KNUCKLE - DESCRIPTION)

OPERATION

The wheel bearing and hub are pressed into the steering knuckle. (Refer to 2 - SUSPENSION/ FRONT/KNUCKLE - OPERATION)

DIAGNOSIS AND TESTING - WHEEL BEARING AND HUB

The wheel bearing is designed for the life of the vehicle and requires no type of periodic maintenance. The following procedure may be used for diagnosing the condition of the wheel bearing and hub.

With the wheel, disc brake caliper, and brake rotor removed, rotate the wheel hub. Any roughness or resistance to rotation may indicate dirt intrusion or a failed hub bearing. If the bearing exhibits any of these conditions during diagnosis, the hub bearing will require replacement. Do not attempt to disassemble the bearing for repair. If the wheel bearing is disassembled for any reason, it must be replaced.

Damaged bearing seals and the resulting excessive grease loss may also require bearing replacement. Moderate grease weapage from the bearing is considered normal and should not require replacement of the wheel bearing.

HUB / BEARING (Continued)

To diagnose a bent hub, (Refer to 5 - BRAKES/HYDRAULIC/MECHANICAL/ROTORS - DIAGNOSIS AND TESTING) for the procedure on measuring hub runout.

REMOVAL

The wheel bearing and hub are pressed into the knuckle. (Refer to 2 - SUSPENSION/FRONT/KNUCKLE - REMOVAL)

INSTALLATION

The wheel bearing and hub are pressed into the knuckle. (Refer to 2 - SUSPENSION/FRONT/KNUCKLE - INSTALLATION)

KNUCKLE

DESCRIPTION - STEERING KNUCKLE

The steering knuckle is a single casting with legs machined for attachment to the front strut assembly on the top, lower control arm ball joint on the bottom, and steering linkage on the trailing end (Fig. 1). The steering knuckle also has two machined, drilled and tapped legs on the leading end casting to support and align the front disc brake caliper adapter.

The knuckle supports the wheel bearing and hub (Fig. 1). The wheel hub is pressed into a sealed-for-life wheel bearing that is pressed into the steering knuckle. A retainer plate also holds the bearing in place. The hub supports the driveshaft outer constant velocity (C/V) joint. Each is splined and meshes in the center of the hub. The outer C/V joint is retained to the hub using a nut. The nut is locked to the outer C/V stub shaft using a nut retainer and cotter pin.

The wheel bearing is a Unit 1 type cartridge bearing that requires no maintenance. The wheel bearing can be serviced separately from the hub.

The hub has five studs pressed into its flange.

OPERATION - STEERING KNUCKLE

The steering knuckle pivots with the strut assembly between the lower ball joint and the pivot bearing in the strut assembly. The steering gear outer tie rod end connects to the trailing end of each knuckle, allowing the vehicle to be steered.

The center of the knuckle supports the hub, wheel bearing and axle shaft.

The hub and wheel bearing work together. The wheel bearing has internal bearings that allow the hub to rotate with the driveshaft and the tire and wheel assembly. The hub's five studs mount the tire and wheel to the vehicle.

DIAGNOSIS AND TESTING - STEERING KNUCKLE

The front suspension steering knuckle is not a repairable component of the front suspension. It must be replaced if found to be damaged in any way. If it is determined that the steering knuckle is bent when servicing the vehicle, no attempt is to be made to straighten the steering knuckle.

REMOVAL - STEERING KNUCKLE

NOTE: Before proceeding, review all Warnings and Cautions. (Refer to 2 - SUSPENSION/FRONT - WARNING)

(1) Apply the brakes and hold in place.

(2) Raise the vehicle. (Refer to LUBRICATION & MAINTENANCE/HOISTING - STANDARD PROCEDURE)

(3) Remove the front tire and wheel assembly.

(4) Remove the cotter pin, lock nut and spring washer from the hub nut (Fig. 2).

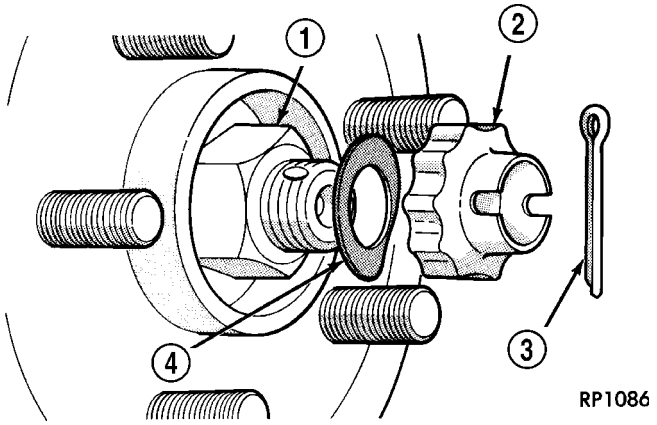

Fig. 2 Hub Nut

1 - HUB NUT
2 - NUT LOCK
3 - COTTER PIN
4 - SPRING WASHER

(5) While the brakes are applied, loosen and remove the hub nut on the end of the driveshaft (Fig. 2).

(6) Release the brakes.

(7) Remove the front disc brake caliper and adapter as an assembly, and the brake rotor from the steering knuckle. Refer to BRAKE ROTOR in the BRAKE section for the procedure.

(8) Remove the nut attaching the outer tie rod to the steering knuckle. To do this, hold the tie rod end stud with a wrench while loosening and removing the nut with a standard wrench or crowfoot wrench (Fig. 3).

KNUCKLE (Continued)

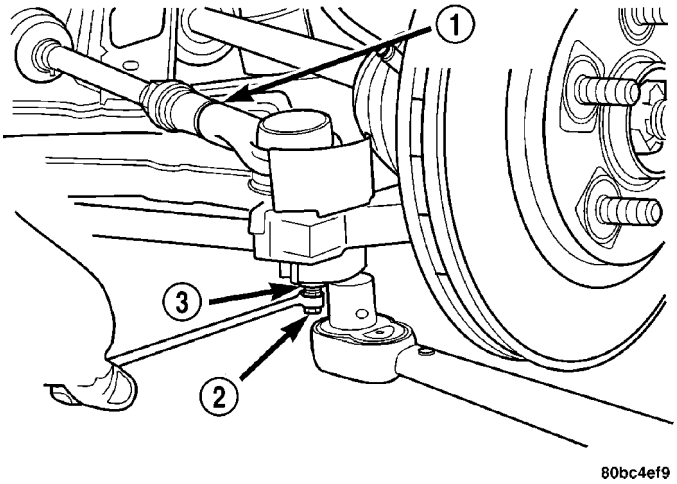

Fig. 3 Tie Rod Nut Removal/Installation

1 - OUTER TIE ROD
2 - STUD
3 - NUT

(9) Remove the tie rod end from the steering knuckle using Remover, Special Tool MB991113 (Fig. 4).

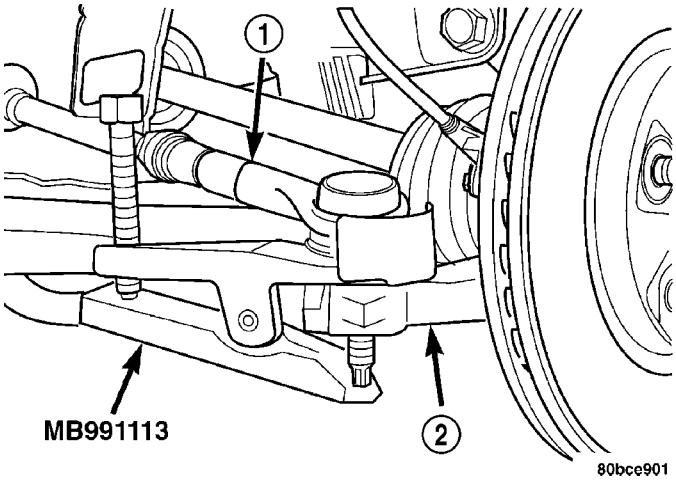

Fig. 4 Tie Rod Removal

1 - OUTER TIE ROD
2 - STEERING KNUCKLE

(10) Remove the tie rod heat shield.

(11) Remove the nut and pinch bolt clamping the ball joint stud to the steering knuckle (Fig. 5).

CAUTION: The strut assembly-to-steering knuckle attaching bolts are serrated and must not be turned during removal. Hold the bolts stationary in the steering knuckles while removing the nuts, then tap the bolts out using a pin punch.

(12) Remove the two bolts attaching the strut to the steering knuckle.

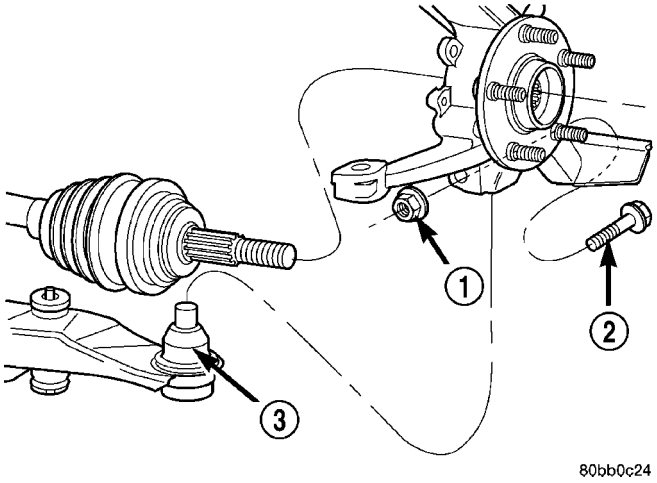

Fig. 5 Ball Joint Bolt And Nut

1 - NUT
2 - BOLT
3 - BALL JOINT

NOTE: Use caution when separating the ball joint stud from the steering knuckle, so the ball joint seal does not get cut.

(13) Separate the ball joint stud from the steering knuckle by prying down on lower control arm and up against the ball joint boss on the steering knuckle (Fig. 6).

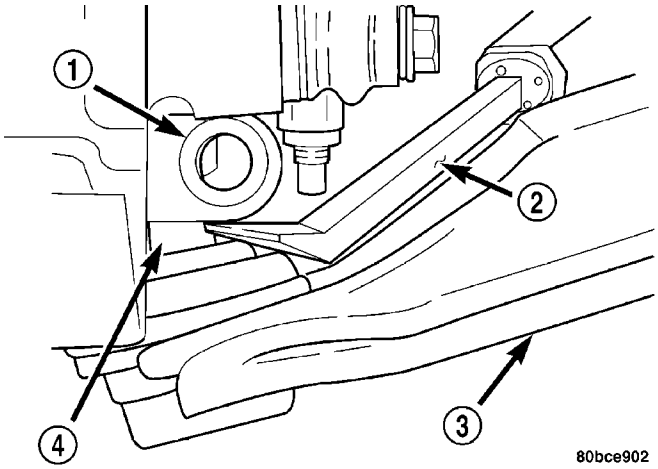

Fig. 6 Separate Ball Joint From Knuckle

1 - STEERING KNUCKLE
2 - PRY BAR
3 - LOWER CONTROL ARM
4 - BALL JOINT STUD

NOTE: Do not allow the driveshaft to hang by the inner C/V joint; it must be supported to keep the joint from separating during this operation.

(14) Pull the steering knuckle off the driveshaft outer C/V joint splines and remove the steering knuckle.

KNUCKLE (Continued)

NOTE: The cartridge type front wheel bearing used on this vehicle is not transferable to the replacement steering knuckle. If the replacement steering knuckle does not come with a wheel bearing, a new bearing must be installed in the steering knuckle. Installation of the new wheel bearing and hub must be done before installing the steering knuckle on the vehicle.

(15) If the wheel bearing and hub need removal, (Refer to 2 - SUSPENSION/FRONT/KNUCKLE - DISASSEMBLY). Do not reuse the wheel bearing.

DISASSEMBLY - STEERING KNUCKLE (WHEEL BEARING AND HUB)

NOTE: The removal and installation of the wheel bearing and hub from the steering knuckle is only to be done with the steering knuckle removed from the vehicle using the following procedure.

(1) Remove steering knuckle, hub, and wheel bearing as an assembly from the vehicle. (Refer to 2 - SUSPENSION/FRONT/KNUCKLE - REMOVAL)

(2) Three wheel studs across from one another require removal from the hub flange. Rotate the hub to align each wheel mounting stud with the notch in the bearing retainer plate before removal. Using Remover, Special Tool C–4150A (Fig. 7), press the three wheel mounting studs out of the hub flange. Remove the wheel mounting studs from the hub through the open notch (Fig. 8).

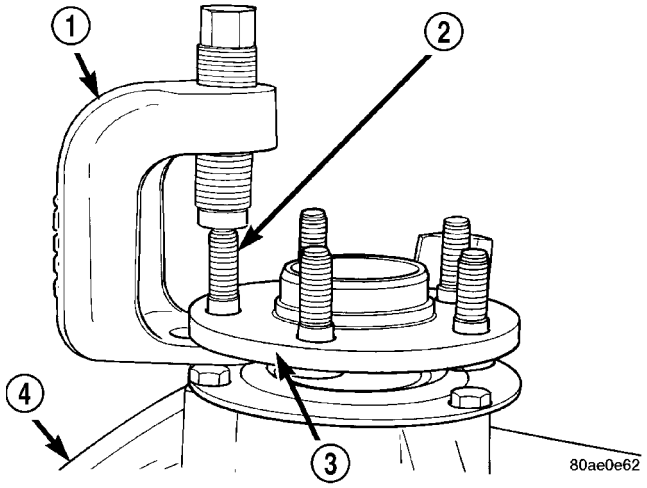

Fig. 7 Special Tool C-4150A

1 - SPECIAL TOOL 4150A
2 - WHEEL MOUNTING STUD
3 - HUB FLANGE
4 - STEERING KNUCKLE

(3) Rotate the hub so the stud mounting holes in the hub are facing in the direction shown in the figure (Fig. 9).

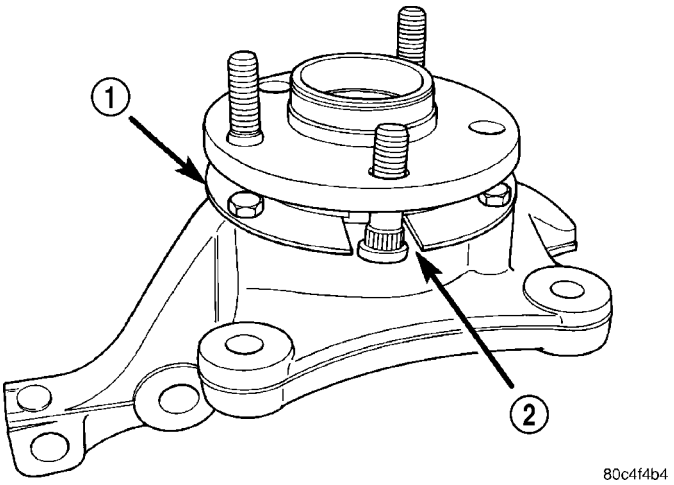

Fig. 8 Stud Removal From Hub

1 - BEARING RETAINER PLATE
2 - NOTCH

(4) Install the Bearing Splitter, Special Tool 1130, between the hub and the bearing retainer plate as shown (Fig. 9). Absence of the three wheel mounting studs allows the bearing splitter to be installed behind the flange. Hand tighten the nuts to hold bearing splitter in place on steering knuckle.

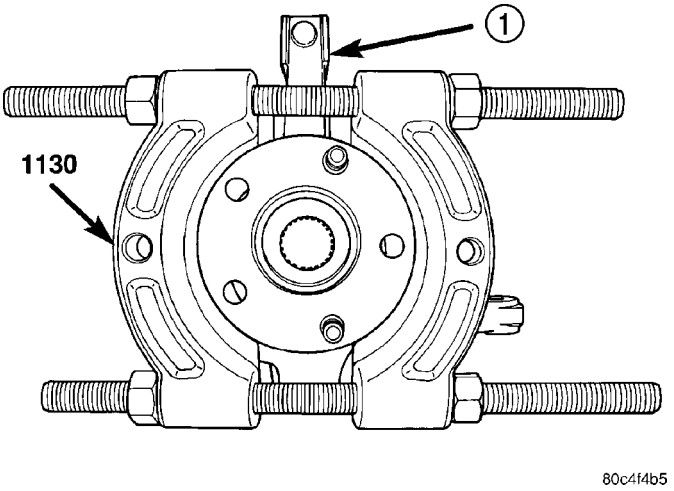

Fig. 9 Bearing Splitter Properly Installed

1 - KNUCKLE

(5) Place the steering knuckle face down in an arbor press supported by the bearing splitter as shown (Fig. 10).

(6) Position Remover/Installer, Special Tool 6644-2, on the small end of the hub (Fig. 10). Using the arbor press, remove the hub from the wheel bearing. The bearing race will normally come out of the wheel bearing with the hub as it is pressed out of the bearing.

(7) Remove the bearing splitter from the steering knuckle.

KNUCKLE (Continued)

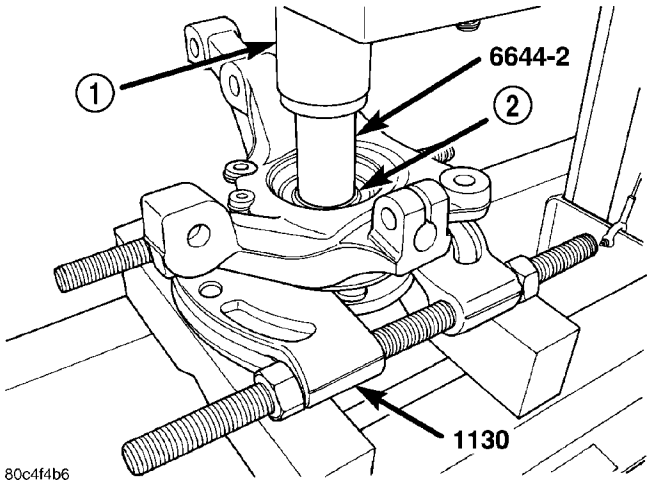

Fig. 10 Steering Knuckle Positioned In Press

1 - PRESS RAM
2 - HUB

(8) Remove the three bolts mounting the bearing retainer plate to the steering knuckle (Fig. 11). Remove the bearing retainer plate from the steering knuckle.

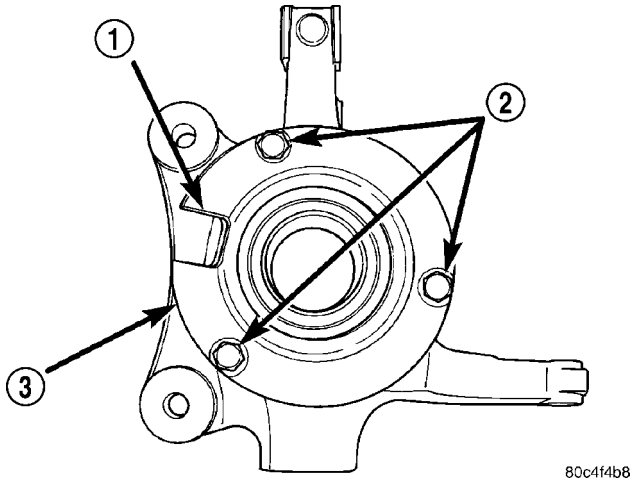

Fig. 11 Wheel Bearing Retainer Plate

1 - NOTCH
2 - BOLTS
3 - BEARING RETAINER PLATE

(9) Place the steering knuckle back in the arbor press face down as shown (Fig. 12). The press support blocks must not obstruct the bearing while it is being pressed out of the steering knuckle.

(10) Place Remover/Installer, Special Tool MB-990799 on the outer race of the wheel bearing (Fig. 12). Press the wheel bearing out of the steering knuckle.

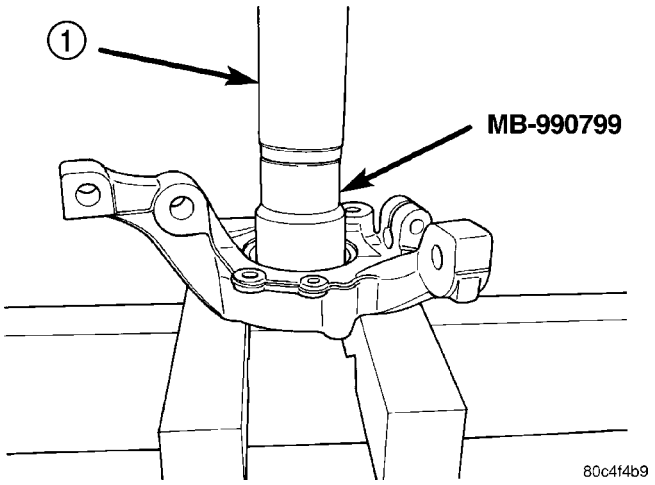

Fig. 12 Wheel Bearing Removal

1 - PRESS RAM

(11) Remove the bearing race that is still pressed onto the hub. To do so, install Bearing Splitter, Special Tool 1130, between the hub flange and the bearing race (Fig. 13). Place the hub, bearing race and bearing splitter in an arbor press as shown (Fig. 13). Place Remover/Installer, Special Tool 6644-2 on end of hub. Press the hub out of the bearing race.

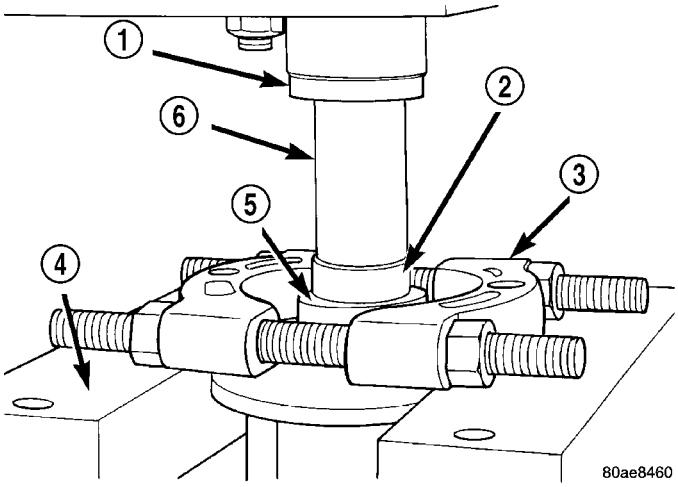

Fig. 13 Bearing Race Removal From Hub

1 - ARBOR PRESS
2 - HUB
3 - SPECIAL TOOL 1130

5 - BEARING RACE
6 - SPECIAL TOOL 6644–2

NOTE: For steering knuckle reassembly, (Refer to 2 - SUSPENSION/FRONT/KNUCKLE - ASSEMBLY).

KNUCKLE (Continued)

ASSEMBLY - STEERING KNUCKLE (WHEEL BEARING AND HUB)

(1) Wipe the bore of the steering knuckle clean of any grease or dirt with a clean, dry shop towel.

(2) Place the steering knuckle in an arbor press with Installer, Special Tool C-4698-2, supporting the steering knuckle (Fig. 14).

(3) Place the NEW wheel bearing into the bore of the steering knuckle. Be sure the wheel bearing is placed squarely into the bore.

(4) Place Installer, Special Tool 5052, on the outer race of the wheel bearing (Fig. 14). Press the wheel bearing into the steering knuckle until it is fully bottomed in the bore of the steering knuckle.

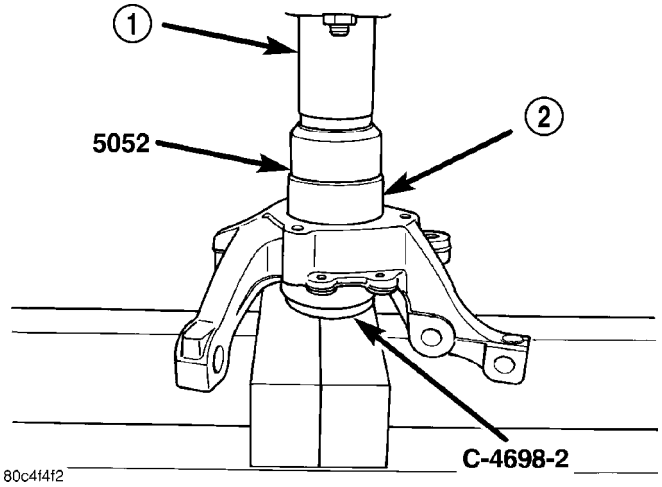

Fig. 14 Wheel Bearing Installation

1 - PRESS RAM
2 - BEARING

(5) Remove the knuckle from the press.

NOTE: Use only the original or identical replacement bolts to mount the bearing retainer plate to the steering knuckle.

(6) Noting the notch location, install the bearing retainer plate on the steering knuckle as shown (Fig. 11). Install the three bearing retainer mounting bolts. Tighten the bearing retainer plate mounting bolts to a torque of 28 N·m (250 in. lbs.).

(7) Install the previously removed wheel mounting studs back into the hub flange. To do so:

(a) Place the studs in the three holes in the hub flange.

(b) Place the hub in the arbor press supported by Special Tool C-4698-1, allowing the first stud to extend down into the tool (Fig. 15).

(c) Press the wheel mounting stud into the hub flange until it is fully seated against the back side on the hub flange.

(d) Remove the hub and tool from the press.

(e) Repeat the steps (b), (c) and (d) on the remaining two studs.

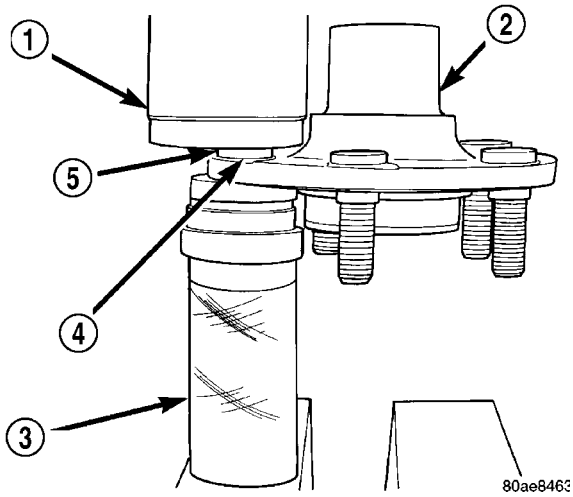

Fig. 15 Wheel Mounting Stud Installation

1 - ARBOR PRESS RAM
2 - HUB
3 - SPECIAL TOOL C-4698–1
4 - NO GAP IS ALLOWED BETWEEN STUD FLANGE AND HUB HERE
5 - WHEEL MOUNTING STUD

(8) Place the steering knuckle with the wheel bearing installed back in the arbor press with the smaller end of Remover/Installer, Special Tool MB-990799, supporting the inner race of the wheel bearing as shown (Fig. 16).

(9) Place the hub in the wheel bearing making sure it is square with the bearing inner race (Fig. 16). Press the hub into the wheel bearing until it is fully bottomed in the wheel bearing.

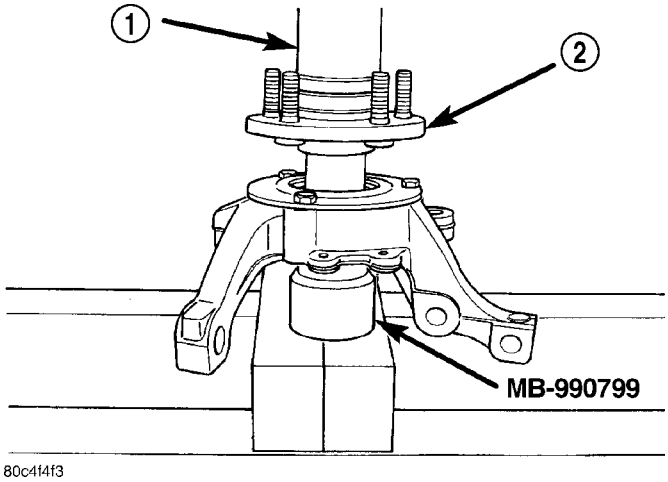

Fig. 16 Hub Installation

1 - PRESS RAM
2 - HUB

(10) Remove the steering knuckle and tools from the press.

(11) Verify the hub turns smoothly without rubbing or binding.

KNUCKLE (Continued)

(12) Install the steering knuckle on the vehicle. (Refer to 2 - SUSPENSION/FRONT/KNUCKLE - INSTALLATION)

INSTALLATION - STEERING KNUCKLE

(1) Slide the hub of the steering knuckle onto the splines on the driveshaft C/V joint.

(2) Install the steering knuckle onto the ball joint stud aligning the bolt hole in the knuckle boss with the notch formed in the side of the ball joint stud.

(3) Install a new ball joint stud pinch bolt and nut (Fig. 5). Tighten the nut to a torque of 95 N·m (70 ft. lbs.).

CAUTION: The strut assembly-to-steering knuckle attaching bolts are serrated and must not be turned during installation. Install the nuts while holding the bolts stationary in the steering knuckle.

(4) Position the lower end of the strut assembly in line with the upper end of the steering knuckle and align the mounting holes (Fig. 1). Install the two attaching bolts. The bolts should be installed with so that the nuts face towards the front of the vehicle once installed. Install the nuts. Holding the bolts in place tighten the nuts to a torque of 53 N·m (40 ft. lbs.) plus an additional 90° turn after the specified torque is met.

(5) Place the tie rod heat shield on the steering knuckle arm so that the shield is positioned straight away from the steering gear and tie rod end once installed. Align the hole in the shield with the hole in the steering knuckle arm.

(6) Install the outer tie rod ball stud into the hole in the steering knuckle arm. Start the tie rod attaching nut onto the stud. Hold the tie rod end stud with a wrench while tightening the nut with a standard wrench or crowfoot wrench (Fig. 3). To fully tighten the nut to specifications, use a crowfoot wrench on a torque wrench to turn the nut, and a wrench on the stud. Tighten the nut to a torque of 55 N·m (40 ft. lbs.).

(7) Install the brake rotor, disc brake caliper and adapter. (Refer to 5 - BRAKES/HYDRAULIC/MECHANICAL/ROTOR - INSTALLATION)

(8) Clean all foreign matter from the threads of the driveshaft outer C/V joint.

(9) Install the hub nut in the end of the driveshaft and snug it (Fig. 2).

(10) Have a helper apply the brakes. With vehicle brakes applied to keep brake rotor and hub from turning, tighten the hub nut to a torque of 244 N·m (180 ft. lbs.)

(11) Install the spring washer, lock nut and cotter pin on the hub nut (Fig. 2). Wrap the cotter pin ends tightly around the lock nut (Fig. 17).

(12) Install the tire and wheel assembly. Install the wheel mounting nuts and tighten them to a torque of 135 N·m (100 ft. lbs.).

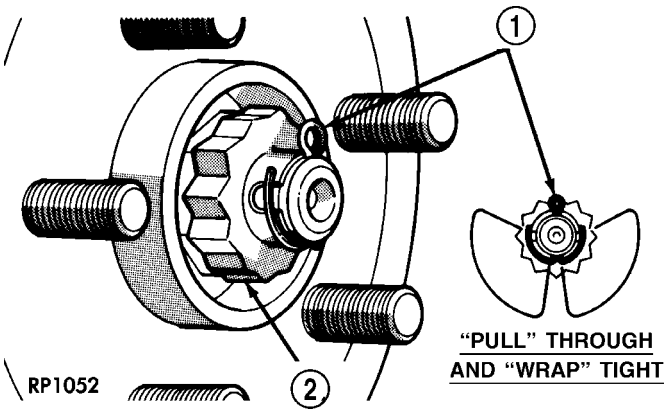

Fig. 17 Correctly Installed Cotter Pin

1 - COTTER PIN
2 - NUT LOCK

(13) Lower the vehicle.

(14) Set the front toe on the vehicle to required specification. (Refer to 2 - SUSPENSION/WHEEL ALIGNMENT - STANDARD PROCEDURE)

LOWER BALL JOINT

DIAGNOSIS AND TESTING - BALL JOINT

With the weight of the vehicle resting on the road wheels, grasp the headless grease fitting as shown (Fig. 18). With no mechanical assistance or added force, attempt to move the grease fitting. If the ball joint is worn, the grease fitting will move. If movement is noted, replace the ball joint.

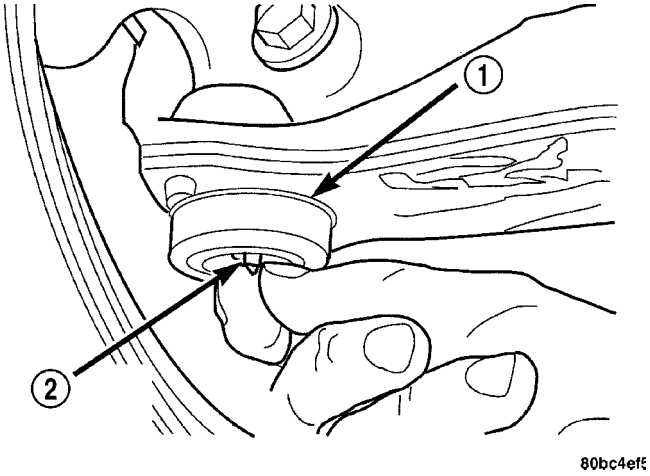

Fig. 18 Checking Ball Joint Wear

1 - BALL JOINT
2 - HEADLESS GREASE FITTING

CAUTION: No attempt should be made to service the headless grease fitting on the ball joint. It has been purposely snapped off by the manufacturer to avoid over-greasing.

LOWER BALL JOINT SEAL BOOT

REMOVAL

(1) Remove steering knuckle from vehicle. (Refer to 2 - SUSPENSION/FRONT/KNUCKLE - REMOVAL)

(2) Using a screwdriver or other suitable tool, pry seal boot off of ball joint (Fig. 19).

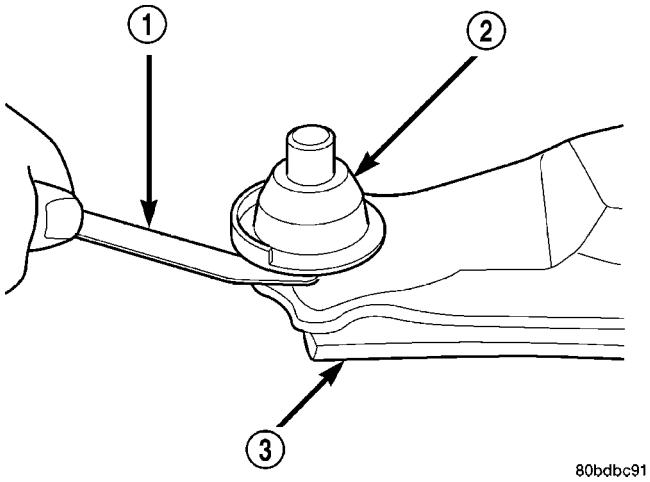

Fig. 19 Seal Boot Removal

1 - TOOL
2 - SEAL BOOT
3 - LOWER CONTROL ARM

INSTALLATION

(1) Wipe off used grease around ball joint stem.

CAUTION: When installing the sealing boot on the ball joint, position the upward lip on the seal boot outside perimeter outward, away from the control arm once installed (Fig. 20). It is there to help shield heat from the sealing boot.

(2) Place NEW ball joint seal boot over ball joint stem. Upward lip located on outside perimeter of seal boot must point outward, away from control arm once installed (Fig. 20).

(3) By hand, start sealing boot over sides of the ball joint.

(4) Position Installer, Special Tool 6758, over sealing boot outer diameter as shown (Fig. 20). By hand, apply pressure to top of Installer until seal boot is pressed squarely down against top surface of lower control arm.

(5) Remove tool.

(6) Remove headless grease fitting on ball joint and replace it with standard zirc-type grease fitting. Do not discard headless grease fitting.

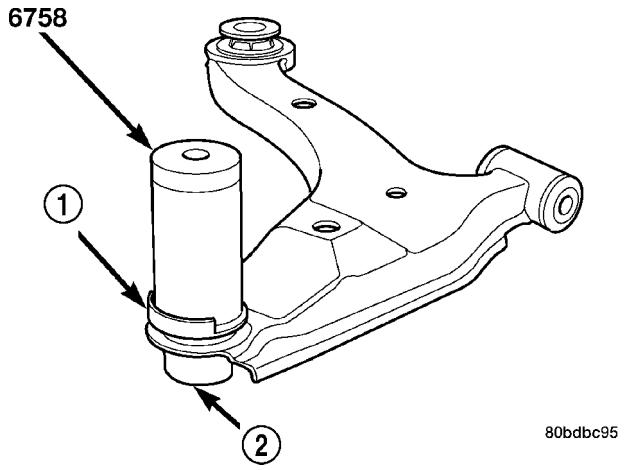

Fig. 20 Seal Boot Installation

1 - SEAL BOOT UPWARD LIP
2 - BALL JOINT

CAUTION: It is important to lubricate the ball joint before installation of steering knuckle to allow proper venting when the seal is filled. If the ball joint is lubricated after installation to knuckle, damage to the seal can occur.

(7) Using a hand operated pump grease gun, fill the ball joint seal boot with Mopar® Multi-Mileage Lube or equivalent until grease pushes out past ball joint stem. Wipe off overfill.

(8) Remove standard zirc-type grease fitting and reinstall headless grease fitting on ball joint to prevent future lubricating. See above caution.

(9) Install steering knuckle. (Refer to 2 - SUSPENSION/FRONT/KNUCKLE - INSTALLATION)

LOWER CONTROL ARM

DESCRIPTION

There is one lower control arm on each side of the vehicle. Each lower control arm is a stamped steel unit using rubber isolated pivot bushings to isolate it from the front suspension crossmember and frame of the vehicle (Fig. 1). The rear bushing can be serviced separately.

The front of the lower control arm is bolted to the front crossmember using a bolt through the center of the rubber pivot bushing. The rear of the lower control arm is mounted to both the front crossmember and the frame rail of the vehicle using a thru-bolt. The thru-bolt goes through both the crossmember and rear lower control arm bushing, threading directly into a caged nut in the frame rail of the vehicle.

The left and right lower control arms are interconnected through a linked rubber isolated stabilizer bar.

LOWER CONTROL ARM (Continued)

The outboard end of each lower control arm connects to the steering knuckle using a ball joint.

The lower control arm connects to the steering knuckle through a ball joint mounted at the outboard end of the arm (Fig. 1). The ball joint is pressed into the lower control arm and has a non-tapered stud with a notch for steering knuckle pinch bolt clearance. The ball joint stud is clamped and locked to the steering knuckle lower leg using a pinch bolt.

The ball joint is lubricated for life during the manufacturing process. Once lubricated for life, the grease fitting head is snapped off by the manufacturer. This is done to eliminate the possibility of lubrication later in the ball joints life thus damaging the non-vented ball joint seal boot.

The ball joint used on this vehicle is replaceable and can be serviced as a separate component of the lower control arm.

OPERATION

The lower control arm supports the lower end of the steering knuckle and allows for the up and down movement of the suspension during the jounce and rebound travel. The lower control arm ball joint connects the arm to the steering knuckle.

The ball joint is a pivotal joint on the lower control arm that allows the knuckle to move up and down, and turn with ease.

DIAGNOSIS AND TESTING - LOWER CONTROL ARM

Inspect the lower control arm for signs of damage from contact with the ground or road debris. If the lower control arm shows any sign of damage, look for distortion. Do not attempt to repair or straighten a broken or bent lower control arm. If damaged, the lower control arm stamping is serviced only as a complete component.

The serviceable components of the lower control arm are: the ball joint, the ball joint grease seal and the lower control arm rear isolator bushing. The front isolator bushing is not replaceable. If the front isolator bushing needs to be replaced, the entire lower control arm must be replaced.

Inspect both lower control arm isolator bushings for severe deterioration and replace lower control arm or rear bushing as required. Inspect the ball joint per the inspection procedure in this section of the service manual and replace as required. (Refer to 2 - SUSPENSION/FRONT/LOWER BALL JOINT - DIAGNOSIS AND TESTING).

REMOVAL - LOWER CONTROL ARM

NOTE: Before proceeding, (Refer to 2 - SUSPENSION/FRONT - WARNING).

(1) Raise the vehicle. (Refer to LUBRICATION & MAINTENANCE/HOISTING - STANDARD PROCEDURE)

(2) Remove the front tire and wheel assembly.

(3) Remove both stabilizer bar links from the vehicle (Fig. 21). Remove each link by holding the upper retainer/nut with a wrench and turning the link bolt.

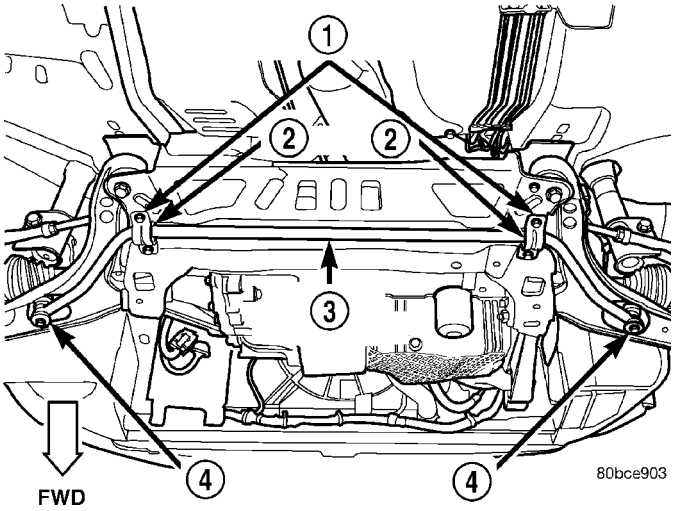

Fig. 21 Stabilizer Bar Links (Typical)

1 - STABILIZER BAR CUSHION RETAINERS
2 - CUSHIONS
3 - FRONT STABILIZER BAR
4 - STABILIZER BAR LINKS

(4) Rotate the forward ends of the stabilizer bar downward. It may be necessary to loosen the stabilizer bar cushion retainer bolts a little to ease any turning resistance.

(5) Remove the nut and pinch bolt clamping the ball joint stud to the steering knuckle (Fig. 22).

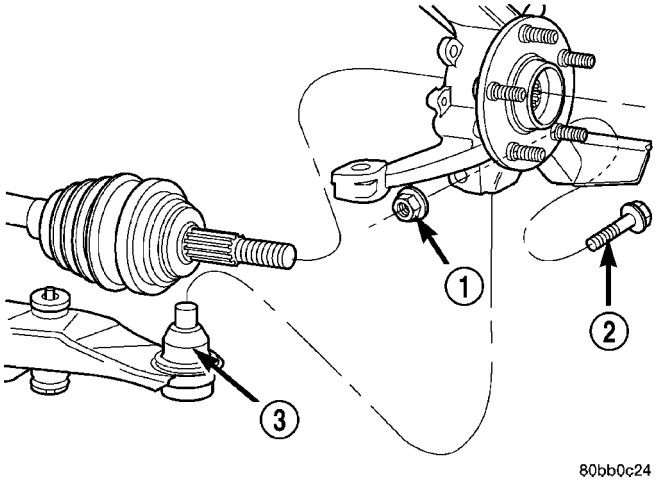

Fig. 22 Ball Joint Bolt And Nut (Typical)

1 - NUT
2 - BOLT
3 - BALL JOINT

LOWER CONTROL ARM (Continued)

CAUTION: After removing the steering knuckle from the ball joint stud, do not pull outward on the knuckle. Pulling the steering knuckle outward at this point can separate the inner C/V joint on the driveshaft. Refer to FRONT DRIVESHAFTS in the DIFFERENTIAL AND DRIVELINE group for further information.

NOTE: Use caution when separating the ball joint stud from the steering knuckle, so the ball joint seal does not get cut.

(6) Separate the ball joint stud from the steering knuckle by prying down on lower control arm and up against the ball joint boss on the steering knuckle (Fig. 6).

(7) If the right lower control arm is being serviced, perform the following:

(a) Remove the screws fastening the front fascia to the reinforcement as necessary in order to access the drive-belt splash shield forward fastener screw (Fig. 23).

(b) Remove the drive-belt splash shield fasteners (Fig. 23). Remove the shield.

(c) Remove the pencil strut from the right front corner of the crossmember and body of the vehicle (Fig. 24). Remove the washer behind the strut from the torque strut bolt.

(d) Remove the bolts mounting the engine torque strut in place (Fig. 24), then remove the engine torque strut from the vehicle.

LOWER CONTROL ARM (Continued)

DISASSEMBLY

DISASSEMBLY - LOWER CONTROL ARM (BALL JOINT)

NOTE: The removal and installation of the lower ball joint from the lower control arm is to be done with the lower control arm removed from the vehicle. (Refer to 2 - SUSPENSION/FRONT/LOWER CONTROL ARM - REMOVAL).

(1) Using a screwdriver or other suitable tool, pry the seal boot off of the ball joint (Fig. 26).

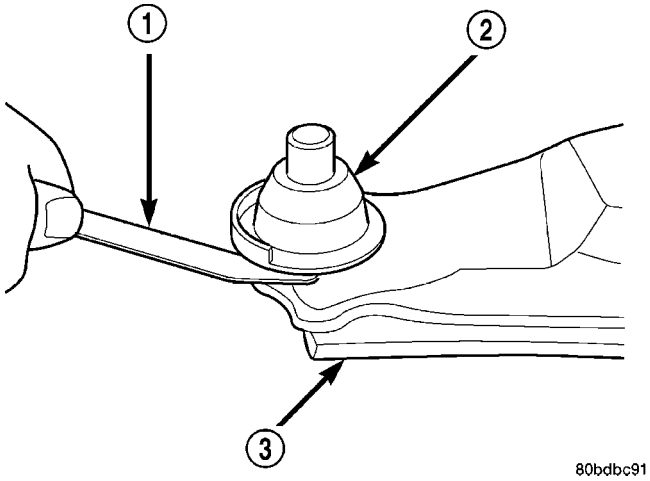

Fig. 26 Seal Boot Removal

1 - TOOL
2 - SEAL BOOT
3 - LOWER CONTROL ARM

(2) Position the Receiver, Special Tool 6908-2, on a hydraulic press to support the lower control arm (Fig. 27). Place the control arm on top of Tool 6908-2 so that the bottom of the ball joint sets into the Receiver cup.

(3) Place the larger end of the Adapter, Special Tool 6804, on top of the ball joint as shown (Fig. 27).

(4) Using the hydraulic press, press the ball joint completely out of the lower control arm, into the receiver.

(5) Remove the tools, ball joint and arm from the hydraulic press.

DISASSEMBLY - LOWER CONTROL ARM (REAR ISOLATOR BUSHING)

NOTE: The removal and installation of the rear isolator bushing from the lower control arm is only to be done with the lower control arm removed from the vehicle (Refer to 2 - SUSPENSION/FRONT/LOWER CONTROL ARM - REMOVAL). The front isolator bushing is not serviceable.

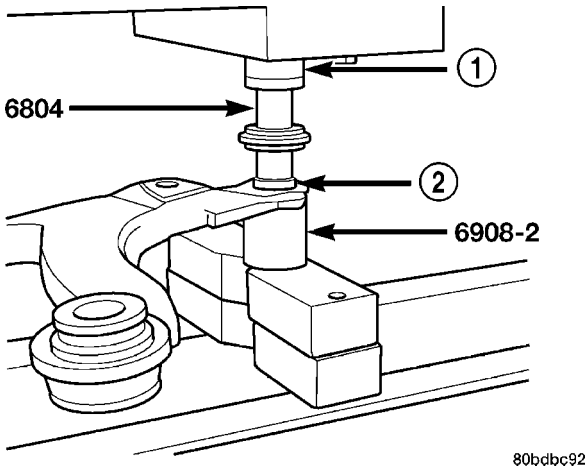

Fig. 27 Ball Joint Removal

1 - PRESS
2 - BALL JOINT

NOTE: To maintain better control when removing the rear isolator bushing, it works best to mount Ball Joint Press, Special Tool C-4212F, in a vise.

(1) Install the Receiver Cup, Special Tool 9356-4, into the cup of the Ball Joint Press, Special Tool C-4212F, and tighten the set screw (Fig. 29).

(2) Install the Remover, Special Tool 9356-2, on the tip of the Ball Joint Press screw-drive.

(3) Install the Reaction Plate, Special Tool 9356-3, over the end of the control arm so that the arrows on the Reaction Plate point toward the bushing flange on the bottom of the arm as shown (Fig. 28).

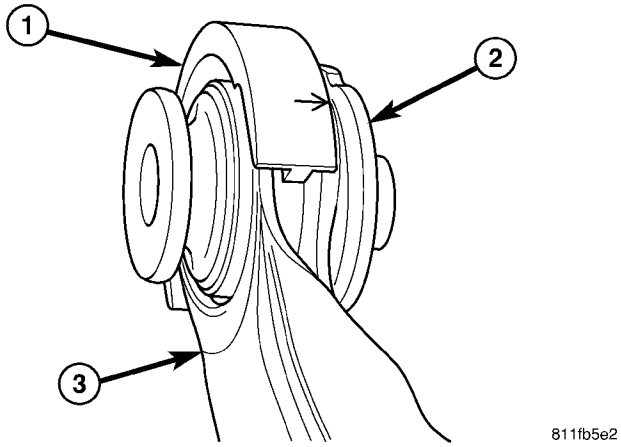

Fig. 28 Reaction Plate Installed On Arm

1 - REACTION PLATE 9356-3
2 - BUSHING FLANGE (BOTTOM OF ARM)
3 - LOWER CONTROL ARM

(4) Place the Reaction Plate (on the lower control arm) against the outer flange of the Receiver Cup as shown (Fig. 29). Line up the arrows on the Reaction Plate with that on the Receiver Cup and tighten the

LOWER CONTROL ARM (Continued)

Press screw-drive until the Remover contacts the outer circumference of the bushing (Fig. 29). Make sure the Remover contacts the bushing circumference evenly all the way around.

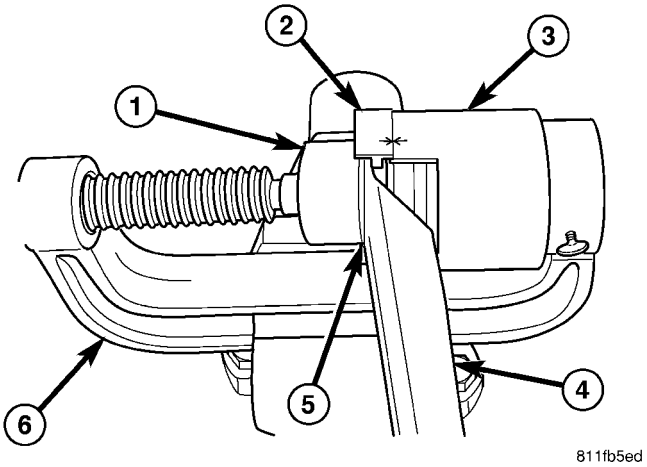

Fig. 29 Tools Positioned For Bushing Removal

1 - REMOVER 9356-2
2 - REACTION PLATE 9356-3
3 - RECEIVER CUP 9356-4
4 - LOWER CONTROL ARM
5 - BUSHING
6 - PRESS C-4212F

(5) Continue to tighten the screw-drive until the bushing is pressed completely out of the lower control arm.

(6) Back off the screw-drive and remove the lower control arm and isolator bushing. Remove the Reaction Plate from the arm.

ASSEMBLY

ASSEMBLY - LOWER CONTROL ARM (BALL JOINT)

CAUTION: When installing a ball joint in its mounting hole in the lower control arm, position the ball joint so the notch in the ball joint stud is facing the lower control arm front isolator bushing (Fig. 30). This will ease assembly of the ball joint to the steering knuckle when the installation of the pinch bolt is attempted.

(1) By hand, position ball joint into it's bore on the lower control arm (Fig. 30). To avoid binding upon installation, be sure the ball joint is not cocked in the bore.

(2) Position the Installer, Special Tool 6758, on a hydraulic press to support the lower control arm (Fig. 31). Place the control arm on top of Tool 6758 in the upside-down position, aligning the ball joint stud squarely with the Installer's cup.

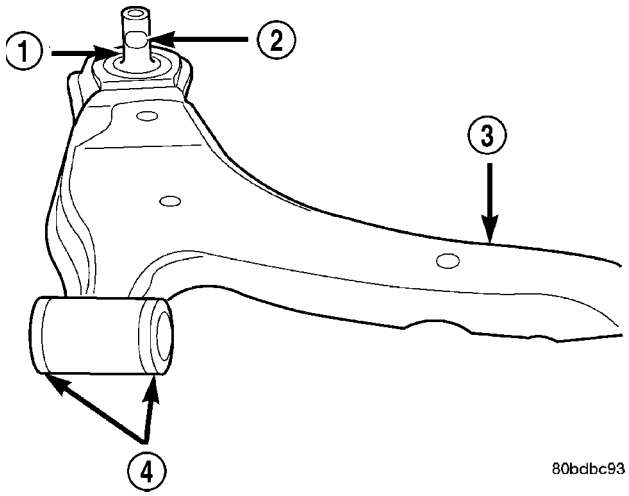

Fig. 30 Ball Joint Alignment

1 - BALL JOINT STUD
2 - NOTCH
3 - LOWER CONTROL ARM
4 - FRONT ISOLATOR BUSHING

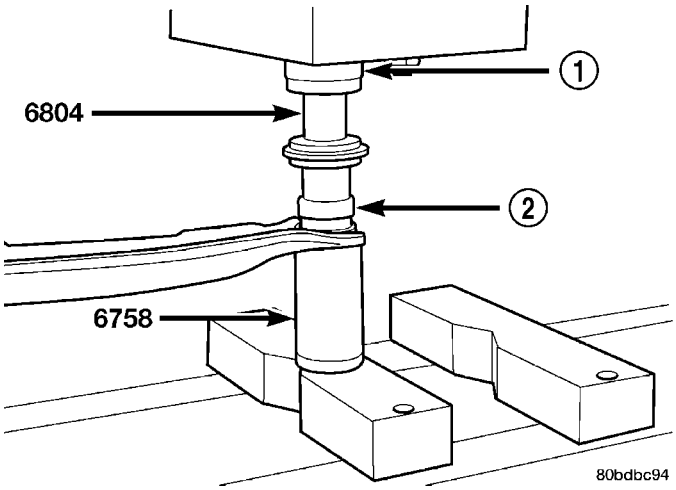

Fig. 31 Ball Joint Installation

1 - PRESS
2 - BALL JOINT

(3) Place the larger end of the Adapter, Special Tool 6804, on top of the ball joint as shown (Fig. 31).

(4) Using the hydraulic press, press the ball joint into the lower control arm until the shoulder on the ball joint bottoms against the lower control arm ball joint bore. Do not apply excessive pressure against ball joint and lower control arm once the ball joint bottoms.

(5) Remove the tools and arm from the hydraulic press.

LOWER CONTROL ARM (Continued)

CAUTION: When installing the sealing boot on the ball joint, position the upward lip on the outside perimeter of the seal boot outward, away from the control arm once installed (Fig. 32). It is there to help shield heat from the sealing boot.

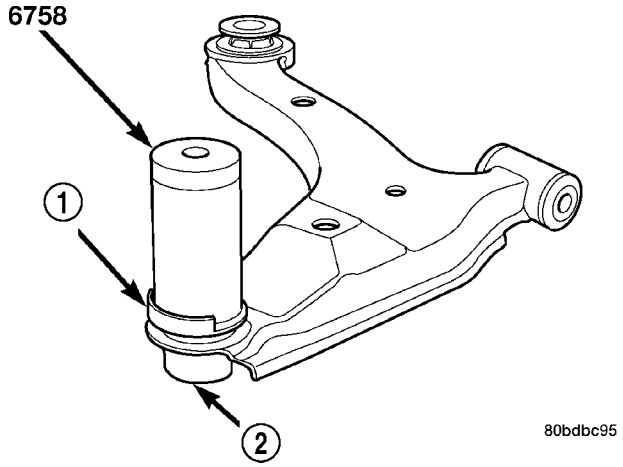

Fig. 32 Seal Boot Installation

1 - SEAL BOOT UPWARD LIP
2 - BALL JOINT

(6) Place a new ball joint seal boot over the ball joint stud. The upward lip located on the outside perimeter of the seal boot must point outward away from the control arm once installed (Fig. 32). Start the sealing boot over the sides of the ball joint by hand.

(7) Position the Installer, Special Tool 6758, over the sealing boot outer diameter as shown (Fig. 32). By hand, apply pressure to the top of the Installer until the seal boot is pressed squarely down against the top surface of lower control arm.

(8) Remove the tool.

(9) If not already installed, install standard zirc-type grease fitting in ball joint.

CAUTION: It is important to lubricate the ball joint before installation of steering knuckle to allow proper venting when the seal is filled. If the ball joint is lubricated after installation to knuckle, damage to the seal can occur.

(10) Using a hand-operated pump grease gun, fill the ball joint seal boot with Mopar® Multi-Mileage Lube or equivalent until grease pushes out past ball joint stem. Wipe off overfill.

(11) Remove standard zirc-type grease fitting and install headless grease fitting from original ball joint to prevent future lubricating. See above Caution. **Be sure to properly clean headless grease fitting prior to installation**.

(12) Install the lower control arm. (Refer to 2 - SUSPENSION/FRONT/LOWER CONTROL ARM - INSTALLATION).

ASSEMBLY - LOWER CONTROL ARM (REAR ISOLATOR BUSHING)

(1) Back the Ball Joint Press, Special Tool C-4212F, set screw outward so it does not extend out into the cup area (Fig. 33).

1 - SET SCREW
2 - CUP AREA

(2) Start the isolator bushing into the bottom of the lower control arm bushing bore by hand. Position the bushing so the voids in the rubber are aligned in relationship to the ball joint as shown (Fig. 34). Place the larger void toward the ball joint.

(3) Install the Installer, Special Tool 9356-1, on the tip of the Ball Joint Press screw drive.

(4) Place the lower control arm upper flange against the cup area of the Ball Joint Press and tighten the screw-drive until the Installer contacts the outer circumference of the bushing (Fig. 35). Make sure the bushing flange sits squarely in the step built into the Installer.

(5) Using hand tools, slowly tighten the screw-drive until the bushing bottoms in the lower control arm bushing bore. Do not overtighten the screw-drive; damage to the bushing, arm or tool can result.

(6) Back off the screw-drive and remove the control arm from the Ball Joint Press.

(7) Install the lower control arm on the vehicle. (Refer to 2 - SUSPENSION/FRONT/LOWER CONTROL ARM - INSTALLATION)

LOWER CONTROL ARM (Continued)

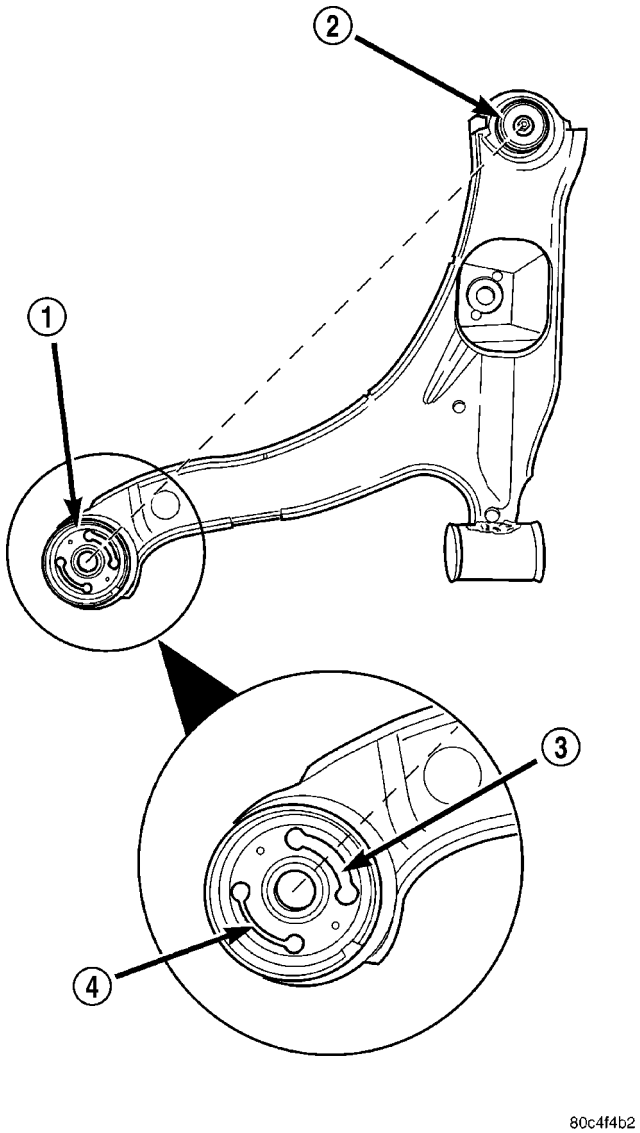

Fig. 34 Aligning Bushing With Ball Joint

1 - REAR ISOLATOR BUSHING
2 - BALL JOINT
3 - WIDE VOID
4 - NARROW VOID

INSTALLATION - LOWER CONTROL ARM

(1) Position the lower control arm into the crossmember (Fig. 25). Install, but do not fully tighten, the rear pivot bolt attaching the lower control arm to the front suspension crossmember and frame rail. Install, but do not fully tighten, the front pivot bolt attaching the lower control arm to the front suspension crossmember.

(2) With no weight on the lower control arm, tighten the lower control arm rear pivot (and suspension crossmember) bolt to a torque of 250 N·m (185 ft. lbs.), then tighten the lower control arm front pivot bolt to a torque of 170 N·m (125 ft. lbs.).

(3) Install the ball joint stud into the steering knuckle aligning the bolt hole in the knuckle boss with the notch formed in the side of the ball joint stud.

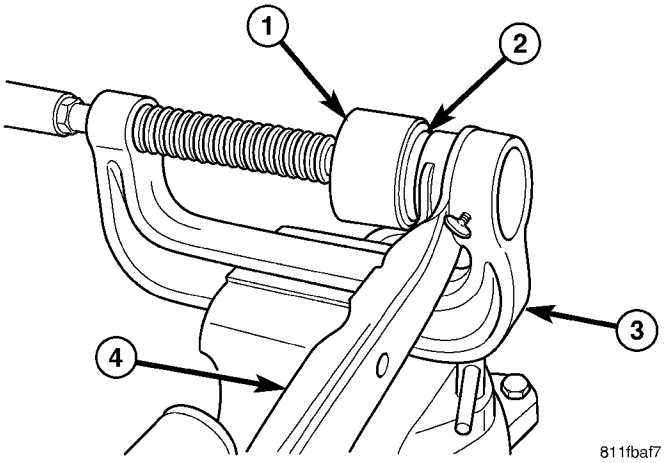

Fig. 35 Tools Positioned For Bushing Installation

1 - INSTALLER 9356-1
2 - BUSHING
3 - PRESS C-4212F
4 - LOWER CONTROL ARM

(4) If the right lower control arm has been serviced, perform the following:

(a) Install the engine torque strut (Fig. 24). To properly align and tighten the torque strut, (Refer to 9 - ENGINE/ENGINE MOUNTING/TORQUE STRUT - ADJUSTMENTS).

(b) Install the washer on the end of the stud extending from the torque strut bolt (Fig. 24).

(c) Install the pencil strut to the right front corner of the crossmember and body of the vehicle (Fig. 24). Tighten the pencil strut nuts to a torque of 52 N·m (38 ft. lbs.).

(d) Install the drive-belt splash shield and fasteners (Fig. 23).

(e) Install the screws fastening the front fascia to the reinforcement (Fig. 23).

(5) Install a new ball joint stud pinch bolt and nut (Fig. 22). Tighten the nut to a torque of 95 N·m (70 ft. lbs.).

(6) Rotate the forward ends of the stabilizer bar into mounting position.

(7) Clean the threads of the stabilizer bar link bolts, then apply Mopar® Lock And Seal or equivalent to the threads.

(8) Install both stabilizer bar links back on vehicle (Fig. 21). Start each stabilizer bar link bolt with bushing from the bottom, through the stabilizer bar, inner link bushings, lower control arm, and into the upper retainer/nut and bushing (Fig. 1). Do not fully tighten the link assemblies at this time.

(9) Lower the vehicle to ground level.

LOWER CONTROL ARM (Continued)

NOTE: It may be necessary to put the vehicle on a platform hoist or alignment rack to gain access to the stabilizer bar mounting bolts with the vehicle at curb height.

(10) Tighten each stabilizer bar link by holding the upper retainer/nut with a wrench and turning the link bolt. Tighten each link bolt to a torque of 29 N·m (260 in. lbs.).

(11) If previously loosened, tighten the stabilizer bar cushion retainer bolts to a torque of 25 N·m (220 in. lbs.).

STABILIZER BAR

DESCRIPTION

The stabilizer bar interconnects both front lower control arms of the vehicle and is attached to the front suspension crossmember (Fig. 1).

Attachment of the stabilizer bar to the front suspension crossmember is through 2 rubber-isolator cushion and retainers (Fig. 1). The stabilizer bar attachment to the lower control arm is done by utilizing an isolated stabilizer bar link at each arm. All components of the stabilizer bar are serviceable.

OPERATION

The stabilizer bar helps control vehicle body roll. Jounce and rebound movements affecting one wheel are partially transmitted to the opposite wheel of the vehicle through the stabilizer bar.

REMOVAL

NOTE: Before proceeding, (Refer to 2 - SUSPENSION/FRONT - WARNING).

(1) Raise the vehicle. (Refer to LUBRICATION & MAINTENANCE/HOISTING - STANDARD PROCEDURE)

(2) Remove both stabilizer bar links from the vehicle (Fig. 36). Remove each link by holding the upper retainer/nut with a wrench and turning the link bolt.

(3) Remove the stabilizer bar cushion retainer bolts and retainers (Fig. 36), and remove the stabilizer bar with cushions attached from the vehicle.

(4) To remove the cushions from the stabilizer bar, peel back each cushion at the slit and roll it off the bar.

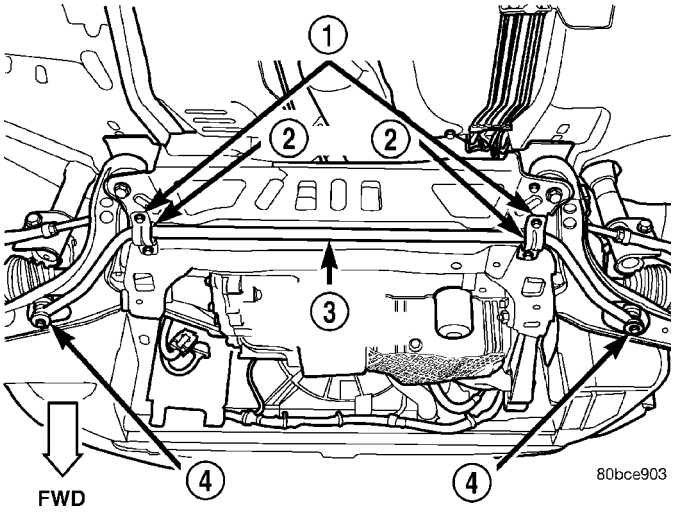

Fig. 36 Stabilizer Bar (Typical)

1 - STABILIZER BAR CUSHION RETAINERS
2 - CUSHIONS
3 - FRONT STABILIZER BAR
4 - STABILIZER BAR LINKS

INSPECTION

Inspect for broken, cracked or distorted stabilizer bar cushions and retainers. Inspect for worn or damaged stabilizer bar links (Fig. 1).

INSTALLATION

NOTE: Before stabilizer bar installation, inspect the cushions and links for excessive wear, cracks, damage and distortion. Replace any pieces failing inspection.

(1) If removed, install the stabilizer bar cushions on the stabilizer bar utilizing the slit in each cushion. Position the cushions at each end of the bar's straight beam, just before it begins to curve.

NOTE: Before installing the stabilizer bar, make sure the bar is not upside-down. The stabilizer bar must be installed with the curve on the outboard ends of the bar facing downward to clear the control arms once fully installed (Fig. 37).

(2) First, place the stabilizer bar in position on the front suspension crossmember. The slits in each cushion must point toward the front of the vehicle and sit directly on top of the raised beads formed into the stamping on the crossmember. Next, install the cushion retainers, matching the raised beads formed into the cushion retainers to the grooves formed into the cushions. Install the cushion retainer bolts, but do not completely tighten them at this time.

STABILIZER BAR (Continued)

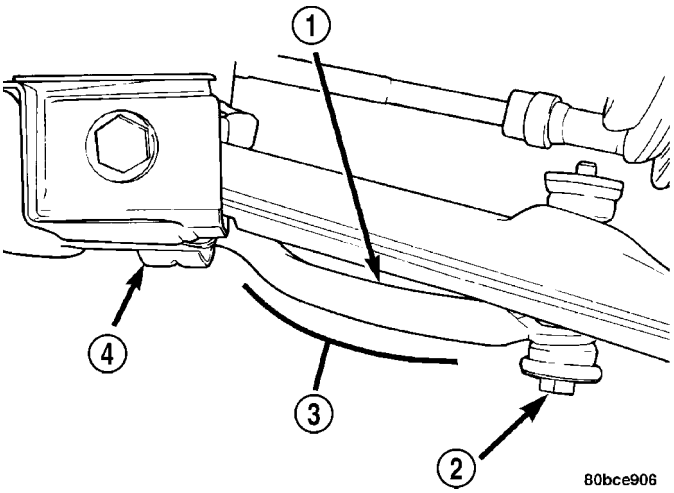

Fig. 37 Downward Curve

1 - STABILIZER BAR
2 - LINK
3 - DOWNWARD CURVE
4 - CUSHION RETAINER

(3) Clean the threads of the stabilizer bar link bolts, then apply Mopar® Lock And Seal or equivalent to the threads.

(4) Install both stabilizer bar links back on vehicle (Fig. 36). Start each stabilizer bar link bolt with bushing from the bottom, through the stabilizer bar, inner link bushings, lower control arm, and into the upper retainer/nut and bushing (Fig. 1). Do not fully tighten the link assemblies at this time.

(5) Lower the vehicle.

NOTE: It may be necessary to put the vehicle on a platform hoist or alignment rack to gain access to the stabilizer bar mounting bolts with the vehicle at curb height.

(6) Tighten each stabilizer bar link by holding the upper retainer/nut with a wrench and turning the link bolt. Tighten each link bolt to a torque of 29 N·m (260 in. lbs.).

(7) Tighten the stabilizer bar cushion retainer bolts to a torque of 25 N·m (220 in. lbs.).

STRUT ASSEMBLY

DESCRIPTION

A Macpherson type design strut assembly is used in place of the front suspension upper control arm and upper ball joint (Fig. 1). The bottom of the strut mounts directly to the steering knuckle using 2 attaching bolts and nuts going through the strut clevis bracket and steering knuckle. The top of the strut mounts directly to the strut tower of the vehicle using the three threaded studs on the strut assemblies upper mount.

The strut assembly includes the following components (Fig. 1):

- Upper mount (rubber isolated)
- Upper spring seat and bearing
- Dust shield
- Jounce bumper
- Coil spring
- Lower spring isolator
- Strut (damper)

Each component is serviced by removing the strut assembly from the vehicle and disassembling it.

Coil springs are rated separately for each corner or side of the vehicle depending on optional equipment and type of vehicle service. If a coil spring requires replacement, be sure that it is replaced with a spring meeting the correct load rating for the vehicle and its specific options.

OPERATION

The strut assembly cushions the ride of the vehicle, controlling vibration, jounce and rebound of the suspension.

The coil spring controls ride quality and maintains proper ride height.

The spring isolators isolate the coil spring at the top and bottom from coming into metal-to-metal contact with the upper mounting seat and the strut.

The jounce bumper limits suspension travel and metal-to-metal contact under full jounce condition.

The strut dampens jounce and rebound motions of the coil spring and suspension.

DIAGNOSIS AND TESTING - STRUT ASSEMBLY (FRONT)

Inspect the strut assembly for the following conditions (Fig. 39):

- Inspect for a damaged or broken coil spring.
- Inspect for a torn or damaged strut assembly dust shield.
- Lift the dust shield and inspect the strut assembly for evidence of fluid running from the upper end of the strut fluid reservoir. (Actual leakage will be a stream of fluid running down the side and dripping off lower end of unit). A slight amount of seepage between the strut shaft and strut shaft seal is not unusual and does not affect performance of the strut assembly.
- Lift the dust shield and inspect the jounce bumper for signs of damage or deterioration.
- Inspect the clearance between the shock tower and the coil spring. Make sure no fasteners are protruding through the shock tower possibly contacting the coil spring and strut. Because of the minimum clearance in this area (Fig. 38), installation of metal

STRUT ASSEMBLY (Continued)

fasteners could damage the coil spring coating and lead to a corrosion failure of the spring.

CAUTION: At no time when servicing a vehicle can a sheet metal screw, bolt or other metal fastener be installed into the shock tower to take the place of an original plastic clip. Also, do not drill holes into the front shock tower for the installation of any metal fasteners into the shock tower area indicated (Fig. 38).

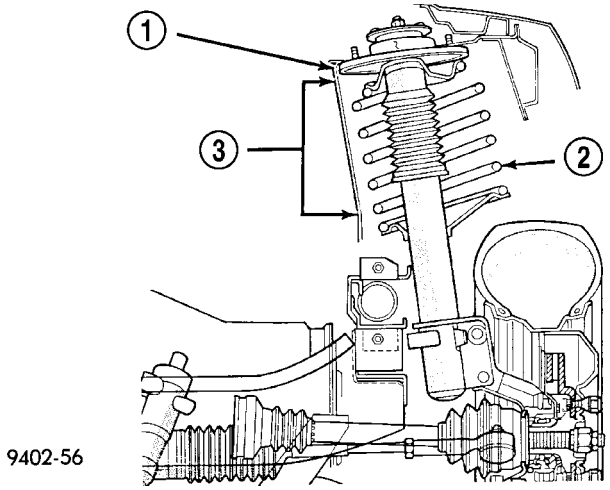

Fig. 38 Shock Tower Area (Typical)

1 - SHOCK TOWER
2 - COIL SPRING
3 - NO SHEET METAL SCREWS, BOLTS, OR ANY OTHER METAL FASTENERS ARE TO BE INSTALLED INTO SHOCK TOWER IN THIS AREA. ALSO, NO HOLES ARE TO BE DRILLED INTO SHOCK TOWER IN THIS SAME AREA.

REMOVAL

NOTE: Before proceeding, (Refer to 2 - SUSPENSION/FRONT - WARNING).

(1) Raise the vehicle. (Refer to LUBRICATION & MAINTENANCE/HOISTING - STANDARD PROCEDURE)

(2) Remove tire and wheel assembly.

(3) If both strut assemblies are to be removed, mark the strut assemblies right or left according to which side of the vehicle they were removed from.

(4) Remove the screw securing the ground strap to the rear of the strut (Fig. 40).

(5) If the vehicle is equipped with Antilock brakes (ABS), remove the screw securing the ABS wheel speed sensor to the rear of the strut (Fig. 40).

CAUTION: The strut assembly-to-steering knuckle attaching bolts are serrated and must not be turned during removal. Hold the bolts stationary in the steering knuckle while removing the nuts, then tap the bolts out using a pin punch.

2 - GROUND STRAP
3 - GROUND STRAP SCREW
4 - ABS SENSOR BRACKET SCREW (IF EQUIPPED)

STRUT ASSEMBLY (Continued)

(6) Remove the two bolts attaching the strut to the steering knuckle (Fig. 1).

(7) Lower the vehicle just enough to open the hood, but without letting the tires touch the floor.

(8) Remove the three nuts attaching the upper mount of the strut assembly to the vehicle's strut tower (Fig. 41).

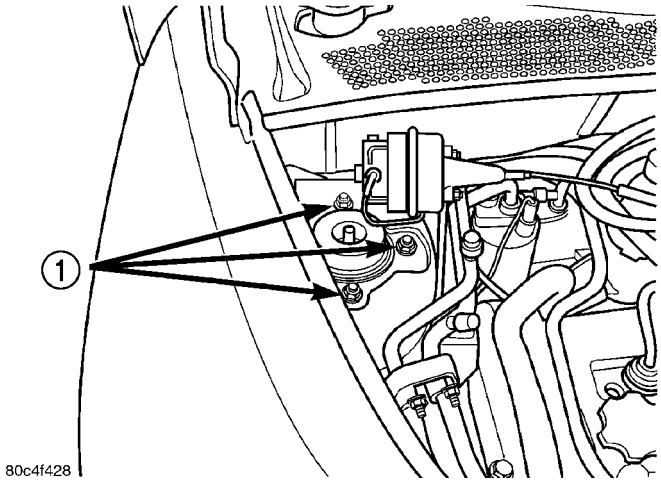

Fig. 41 Upper Mounting Nuts

1 - NUTS

(9) Remove the strut assembly from the vehicle.

(10) For disassembly, (Refer to 2 - SUSPENSION/FRONT/STRUT - DISASSEMBLY).

DISASSEMBLY

The Strut assembly must be removed from the vehicle for it to be disassembled and assembled. (Refer to 2 - SUSPENSION/FRONT/STRUT - REMOVAL)

For the disassembly and assembly of the strut assembly, use strut spring compressor, Pentastar Service Equipment (PSE) tool W-7200, or the equivalent, to compress the coil spring. Follow the manufacturer's instructions closely.

(1) If both struts are being serviced at the same time, mark the coil spring and strut assembly according to which side of the vehicle the strut was removed from, and which strut the coil spring was removed from.

(2) Position the strut assembly in the strut coil spring compressor following the manufacturers instructions. Set the lower hooks (Fig. 42), then set the upper hooks (Fig. 43). Position the strut clevis bracket straight outward away from the compressor. Place a clamp on the lower end of the coil spring, so the strut is held in place once the strut shaft nut is removed (Fig. 42).

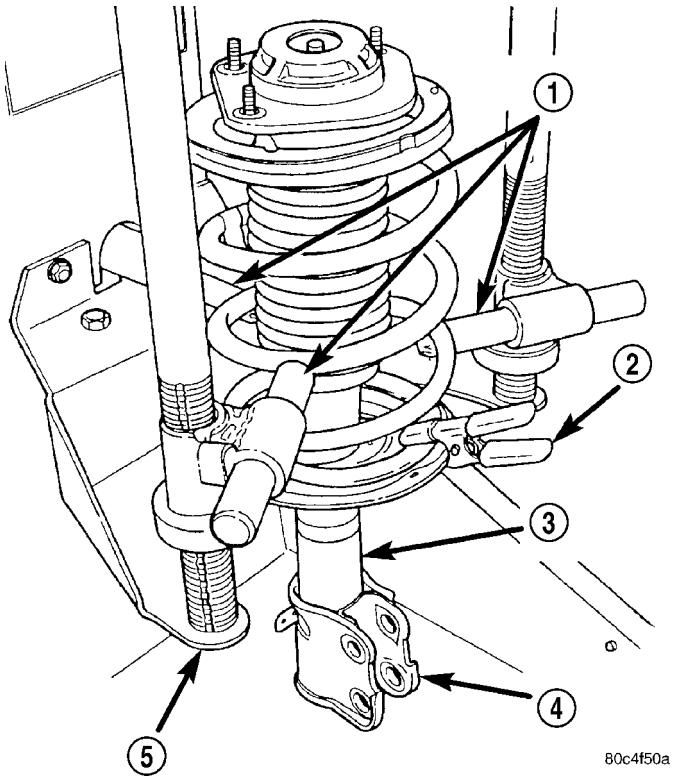

Fig. 42 Strut Assembly In Compressor (Lower)

1 - LOWER HOOKS
2 - CLAMP
3 - STRUT ASSEMBLY
4 - CLEVIS BRACKET
5 - SPRING COMPRESSOR

WARNING: DO NOT REMOVE THE STRUT SHAFT NUT BEFORE THE COIL SPRING IS COMPRESSED. THE COIL SPRING IS HELD UNDER PRESSURE AND MUST BE COMPRESSED, REMOVING SPRING TENSION FROM THE UPPER MOUNT AND PIVOT BEARING, BEFORE THE SHAFT NUT IS REMOVED.

(3) Compress the coil spring until all coil spring tension is removed from the upper mount.

CAUTION: Never use impact or high speed tools to remove the strut shaft nut. Damage to the strut internal bearings may occur.

(4) Once the spring is sufficiently compressed, install Strut Nut Socket, Special Tool 6864, on the strut shaft retaining nut (Fig. 44). Next, install a socket on the hex on the end of the strut shaft. While holding the strut shaft from turning, remove the nut from the strut shaft.

(5) Remove the upper mount from the strut shaft (Fig. 45).

STRUT ASSEMBLY (Continued)

3 - STRUT
4 - LOWER SPRING ISOLATOR
5 - COIL SPRING
6 - JOUNCE BUMPER
7 - DUST SHIELD
8 - SPRING SEAT AND BEARING (WITH SPRING ISOLATOR)
9 - UPPER MOUNT

(6) Remove the upper spring seat and bearing, along with the upper spring isolator as an assembly from the top of the coil spring by pulling them straight up (Fig. 45). The upper spring isolator can be separated from the spring seat and bearing once removed from vehicle.

(7) Remove the dust shield, then the jounce bumper from the strut shaft by pulling each straight up (Fig. 45).

(8) Remove the clamp from the bottom of the coil spring and remove the strut out through the bottom of the coil spring.

(9) Remove the lower spring isolator from the lower spring seat on the strut.

NOTE: If the coil spring needs to be serviced, proceed with the next step, otherwise, proceed with step Step 11.

STRUT ASSEMBLY (Continued)

(10) Release the tension from the coil spring by backing off the compressor drive completely. Push back the compressor hooks and remove the coil spring.

(11) Inspect the strut assembly components for the following and replace as necessary:

- Inspect the strut for any condition of shaft binding over the full stroke of the shaft.
- Inspect the jounce bumper for cracks and signs of deterioration.
- Check the upper mount for cracks and distortion and its retaining studs for any sign of damage.
- Check the upper spring seat and bearing for cracks and distortion.
- Check for binding of the upper spring seat and bearing pivot bearing.
- Inspect the dust shield for rips and deterioration.
- Inspect the upper and lower spring isolators for material deterioration and distortion.
- Inspect the coil spring for any sign of damage to the coating.

NOTE: For reassembly, (Refer to 2 - SUSPENSION/ FRONT/STRUT - ASSEMBLY).

ASSEMBLY

NOTE: If the coil spring has been removed from the spring compressor, proceed with the next step, otherwise, proceed with step Step 3.

(1) Place the coil spring in the compressor following the manufacturers instructions. Before compressing the spring, rotate the spring so the end of the top coil is directly in the front as shown (Fig. 46).

(2) Slowly compress the coil spring until enough room is available for strut assembly reassembly.

(3) Install the lower spring isolator on the lower spring seat of the strut.

(4) Install the strut through the bottom of the coil spring until the lower spring seat contacts the lower end of the coil spring. Rotate the strut as necessary until the clevis bracket is positioned straight outward away from the compressor (Fig. 42). Install the clamp on the lower end of the coil spring and strut, so the strut is held in place.

(5) Install the jounce bumper on the strut shaft. The jounce bumper is to be installed with the smaller end pointing downward toward the lower seat (Fig. 45).

(6) Install the dust shield on the strut shaft (Fig. 45). The bottom of the dust shield will snap to the retainer on top of the strut housing.

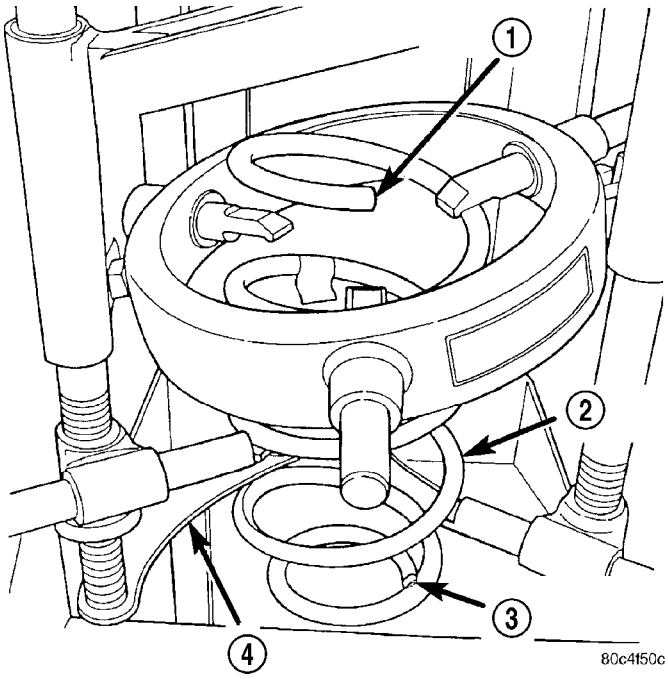

Fig. 46 Upper Coil Spring Positioning

1 - UPPER END OF COIL
2 - COIL SPRING
3 - LOWER END OF COIL
4 - SPRING COMPRESSOR

(7) If disassembled, reinstall the upper spring isolator on the upper spring seat and bearing.

(8) Install the upper spring seat and bearing on top of the coil spring. Position the notch formed into the edge of the upper seat straight out away from the compressor (Fig. 43). It should line up with the very end of the coil spring coil.

(9) Install the strut upper mount over the strut shaft and onto the top of the upper spring seat and bearing. Position the mount so that the third mounting stud on the mount top is inward toward the compressor, opposite the clevis bracket.

CAUTION: Never use impact or high speed tools to install the strut shaft nut. Damage to the strut internal bearings may occur.

(10) Loosely install the retaining nut on the strut shaft. Install Strut Nut Socket (on the end of a torque wrench), Special Tool 6864, on the strut shaft retaining nut (Fig. 44). Next, install a socket on the hex on the end of the strut shaft. While holding the strut shaft from turning, tighten the strut shaft retaining nut to a torque of 75 N·m (55 ft. lbs.).

(11) Slowly release the tension from the coil spring by backing off the compressor drive completely. As the tension is relieved, make sure the upper mount and seat and bearing align properly. Verify the upper mount does not bind.

STRUT ASSEMBLY (Continued)

(12) Remove the clamp from the lower end of the coil spring and strut. Push back the spring compressor upper and lower hooks, then remove the strut assembly from the spring compressor.

(13) Install the strut assembly on the vehicle. (Refer to 2 - SUSPENSION/FRONT/STRUT - INSTALLATION)

INSTALLATION

(1) Install the strut assembly into the strut tower, aligning the three studs on the strut upper mount with the holes in strut tower. Install the three mounting nuts on the studs (Fig. 41). Tighten the three nuts to a torque of 34 N·m (25 ft. lbs.).

(2) Close the hood of the vehicle.

CAUTION: The strut assembly-to-steering knuckle attaching bolts are serrated and must not be turned during installation. Install the nuts while holding the bolts stationary in the steering knuckle.

(3) Position the lower end of the strut assembly in line with the upper end of the steering knuckle and align the mounting holes (Fig. 1). Install the two attaching bolts. The bolts should be installed so that the nuts face towards the front of the vehicle once installed. Install the nuts. Holding the bolts in place tighten the nuts to a torque of 163 N·m (120 ft. lbs.).

(4) If the vehicle is equipped with Antilock brakes (ABS), attach the ABS wheel speed sensor to the rear of the strut (rearward ear) using its mounting screw (Fig. 40). Tighten the mounting screw to a torque of 13 N·m (120 in. lbs.).

(5) Attach the ground strap to the rear of the strut (forward ear) using its mounting screw (Fig. 40). Tighten the mounting screw to a torque of 13 N·m (120 in. lbs.).

(6) Install the tire and wheel assembly. Install and tighten the wheel mounting nuts in proper sequence until all nuts are torqued to half specification. Next, repeat the tightening sequence to the full specified torque of 135 N·m (100 ft. lbs.).

(7) Lower the vehicle.

REAR SUSPENSION

DESCRIPTION - REAR SUSPENSION

The rear suspension design on this vehicle uses coil springs mounted above a twist beam axle assembly (Fig. 1).

The rear suspension consists of these major components:

- Axle
- Coil spring (2)
- Hub and bearing (2)
- Jounce bumper (2)
- Shock absorber (2)
- Spindle (2)
- Stabilizer bar (Fig. 2)
- Watts link assembly

Refer to individual components for additional information.

REAR SUSPENSION (Continued)

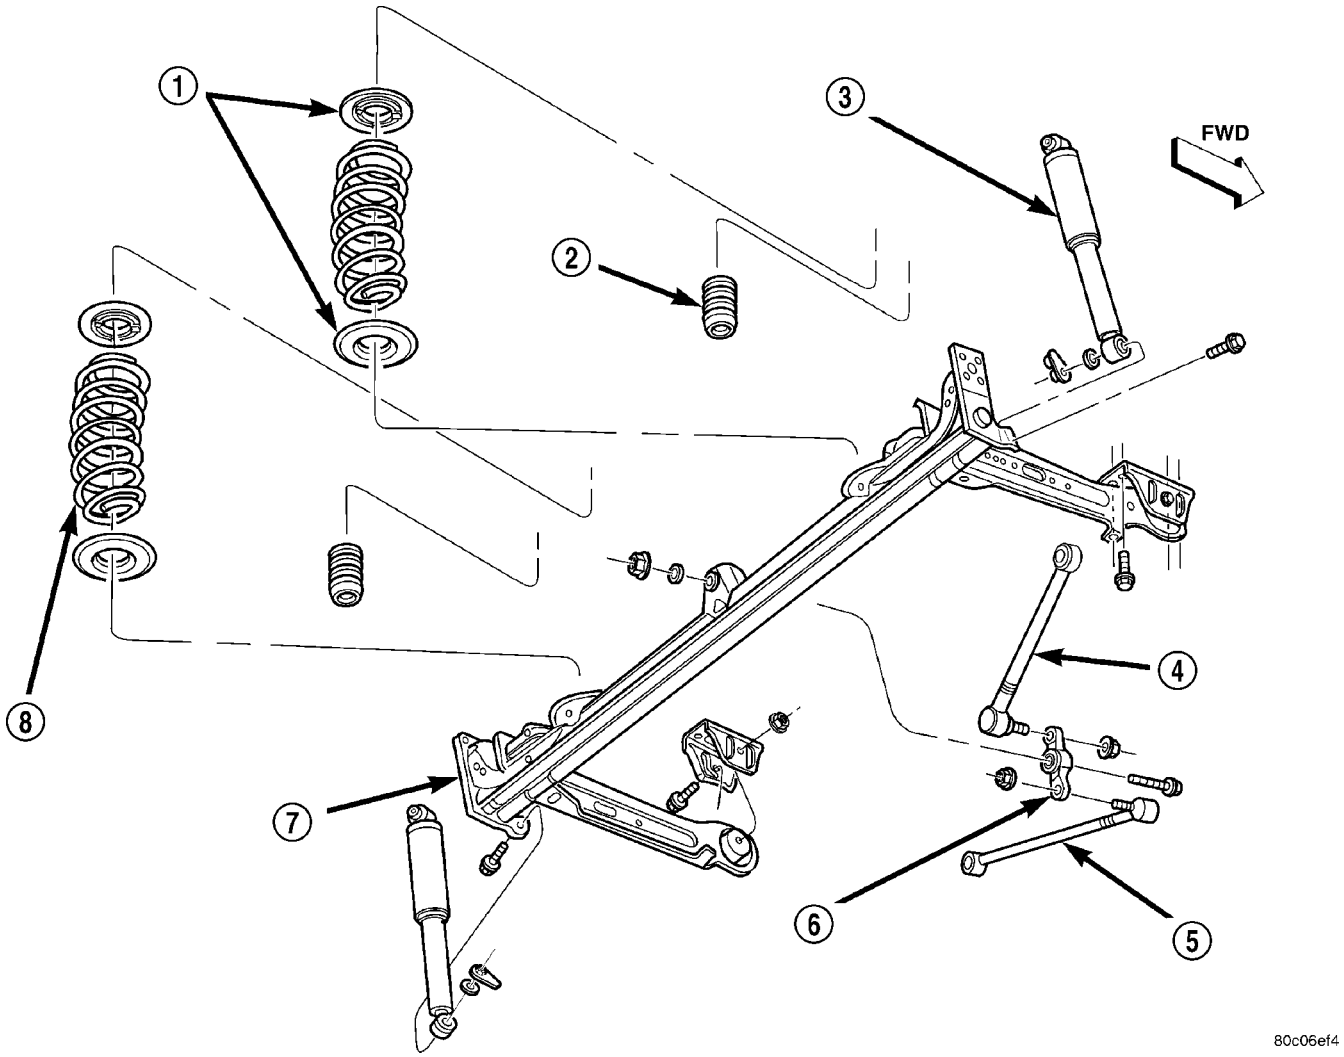

Fig. 1 Rear Suspension System

7 - AXLE
8 - COIL SPRING

REAR SUSPENSION (Continued)

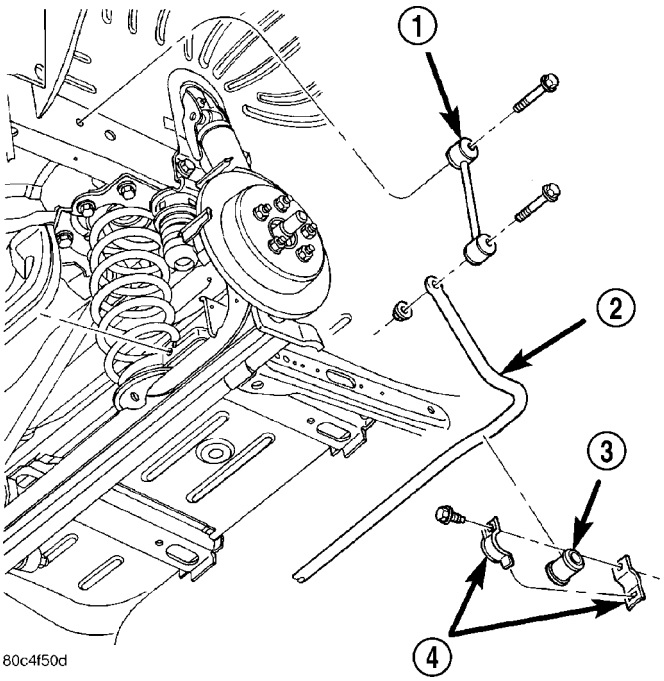

Fig. 2 Stabilizer Bar

1 - LINK
2 - STABILIZER BAR
3 - CUSHION
4 - RETAINER

OPERATION - REAR SUSPENSION

The rear suspension is designed to handle the various load requirements of the vehicle. As the vehicle moves along traversing bumps and dips, the suspension moves up and down to compensate, allowing for a comfortable, steady ride.

Refer to individual components for additional information.

WARNING

WARNINGS AND CAUTIONS

WARNING: DUST AND DIRT ACCUMULATING ON BRAKE PARTS DURING NORMAL USE MAY CONTAIN ASBESTOS FIBERS FROM PRODUCTION OR AFTERMARKET LININGS. BREATHING EXCESSIVE CONCENTRATIONS OF ASBESTOS FIBERS CAN CAUSE SERIOUS BODILY HARM. EXERCISE CARE WHEN SERVICING BRAKE PARTS. DO NOT SAND, OR GRIND BRAKE LINING UNLESS EQUIPMENT USED IS DESIGNED TO CONTAIN THE DUST RESIDUE. DO NOT CLEAN BRAKE PARTS WITH COMPRESSED AIR OR BY DRY BRUSHING. CLEANING SHOULD BE DONE BY DAMPENING THE BRAKE COMPONENTS WITH A FINE MIST OF WATER, THEN WIPING THE BRAKE COMPONENTS CLEAN WITH A DAMPENED CLOTH. DISPOSE OF CLOTH AND ALL RESIDUE CONTAINING ASBESTOS FIBERS IN AN IMPERMEABLE CONTAINER WITH THE APPROPRIATE LABEL. FOLLOW PRACTICES PRESCRIBED BY THE OCCUPATIONAL SAFETY AND HEALTH ADMINISTRATION (OSHA) AND THE ENVIRONMENTAL PROTECTION AGENCY (EPA) FOR THE HANDLING, PROCESSING, AND DISPOSITION OF DUST OR DEBRIS THAT MAY CONTAIN ASBESTOS FIBERS.

CAUTION: Only frame contact or wheel lift hoisting equipment can be used on this vehicle. It cannot be hoisted using equipment designed to lift a vehicle by the rear axle. If this type of hoisting equipment is used, damage to rear suspension components will occur.

NOTE: If a rear suspension component becomes bent, damaged or fails, no attempt should be made to straighten or repair it. Always replace it with a new component.

AXLE - FRONT WHEEL DRIVE REAR

DESCRIPTION

The steel rear axle on this vehicle is a twist beam design (Fig. 1). It has a tubular torsion tube running through the center of its width. It also has two trailing arms, one extending from each end of the axle forward. Each trailing arm has a rubber pivot bushing pressed into it. Two coil spring perches are mounted to its top surface in line with the rear wheel center.

OPERATION

The rear axle pivots at the forward end of the trailing arms through the bushings. Coil springs mounted on top of the axle support the trailing end. As the rear wheels attached to each end of the axle (through spindles) move over bumps and dips, the axle moves with the wheels, pivoting at the front while exerting varying force against the coil springs.

The torsion tube running through the center of the axle's width acts as an integral tubular stabilizer bar. Jounce and rebound movements affecting one rear wheel are partially transferred to the opposite wheel to help stabilize body roll.

REMOVAL

WARNING: THE AUTOMATIC ADJUSTING FEATURE OF THIS PARKING BRAKE LEVER CONTAINS A CLOCKSPRING LOADED TO APPROXIMATELY 19 POUNDS. DO NOT RELEASE THE AUTOMATIC ADJUSTER LOCKOUT DEVICE UNLESS THE REAR PARKING BRAKE CABLES AND EQUALIZER ARE CONNECTED TO THE LEVER OUTPUT CABLE. KEEP HANDS OUT OF AUTOMATIC ADJUSTER SECTOR AND PAWL AREA. FAILURE TO OBSERVE CAUTION IN HANDLING THIS MECHANISM COULD LEAD TO SERIOUS INJURY.

WARNING: WHEN REPAIRS TO THE PARKING BRAKE LEVER OR CABLES ARE REQUIRED, THE AUTOMATIC ADJUSTER MUST BE LOADED AND LOCKED OUT TO AVOID POSSIBLE INJURY. THE LEVER ADJUSTMENT MECHANISM CAN BE LOADED AND LOCKED OUT AS OUTLINED IN THIS PROCEDURE.

WARNING: THE AIRBAG SYSTEM IS A COMPLEX ELECTROMECHANICAL UNIT. BEFORE ATTEMPTING TO SERVICE ANY COMPONENT NEAR THE OCCUPANT RESTRAINT CONTROLLER (ORC), FIRST DISCONNECT AND ISOLATE THE BATTERY NEGATIVE CABLE. ALLOW THE SYSTEM CAPACITOR TO DISCHARGE FOR TWO (2) MINUTES. FAILURE TO DO THIS COULD RESULT IN ACCIDENTAL AIRBAG DEPLOYMENT AND POSSIBLE PERSONAL INJURY.

NOTE: Before proceeding, (Refer to 2 - SUSPENSION/REAR - WARNING).

(1) Unclip the air cleaner cover (two clips) and move the cover aside.

(2) Disconnect and isolate the battery negative cable from its post on the battery.

(3) Block the tire and wheels so the vehicle does not move once the vehicle parking brake lever is released.

(4) Remove the transmission shift knob as necessary.

(5) Remove the screws attaching the center console, then remove the center console.

(6) Grasp the parking brake lever output cable by hand and pull upward. Continue pulling on the cable until an appropriate sized pin punch (drill bit or locking pin) can be inserted sufficiently through the hole in the left side of the lever mounting bracket (Fig. 3). This will lock the parking brake automatic adjustment mechanism in place and take tension off the parking brake cables. Slowly release the output cable. There should now be slack in the cables.

(7) Remove the rear parking brake cables from the parking brake cable equalizer (Fig. 4).

(8) Raise the vehicle. (Refer to LUBRICATION & MAINTENANCE/HOISTING - STANDARD PROCEDURE)

(9) Remove both rear tire and wheel assemblies from the vehicle.

(10) On vehicles equipped with rear drum brakes:

(a) Remove the bolts securing the drum brake flex hoses to the axle trailing arms.

(b) Remove the brake drum retaining clips, then the drums (Fig. 5).

5 - RETAINER CLIP
6 - DUST CAP
7 - NUT
8 - DISC BRAKE CALIPER

(12) Remove the dust cap from the rear hub and bearing (Fig. 5).

(13) Remove the hub and bearing retaining nut from the spindle, then remove the hub and bearing (Fig. 5).

(14) On vehicles equipped with rear disc brakes, remove the upper return spring, both shoe hold-down clips, then spread the rear parking brake shoes apart at the top enough to clear the shoe anchor and remove the parking brake shoes as an assembly from the disc brake adapter (Fig. 7).

(15) On vehicles equipped with rear drum brakes, to remove the parking brake cables from the brake support plates:

(a) Remove the parking brake cable from the parking brake actuating lever (Fig. 8).

3 - PARK BRAKE CABLE

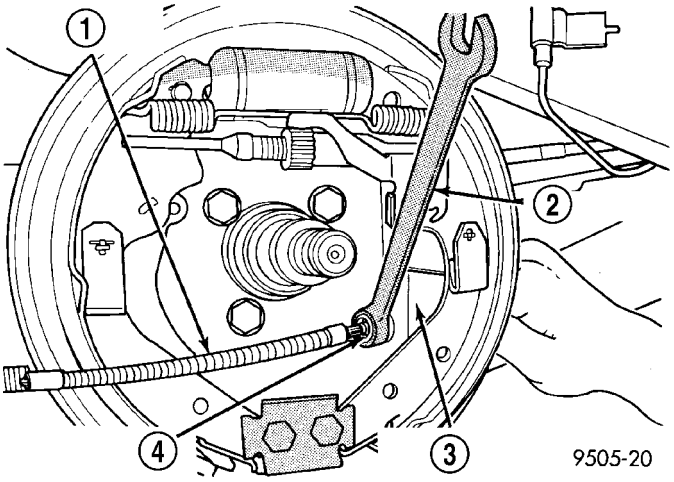

Fig. 10 Parking Brake Cable Removal

1 - PARK BRAKE CABLE
2 - 1/2'' WRENCH
3 - REAR BRAKE SUPPORT PLATE
4 - PARK BRAKE CABLE RETAINER

(16) To remove the parking brake cable from the disc brake adapter on vehicles equipped with rear disc brakes:

(a) Remove the parking brake actuating lever from the parking brake cable (Fig. 11).

(b) Remove the parking brake cable from the rear disc brake adapter. The parking brake cable can be removed from the disc brake adapter using a ½ inch offset box wrench to compress the locking fingers on the parking brake cable retainer (Fig. 12).

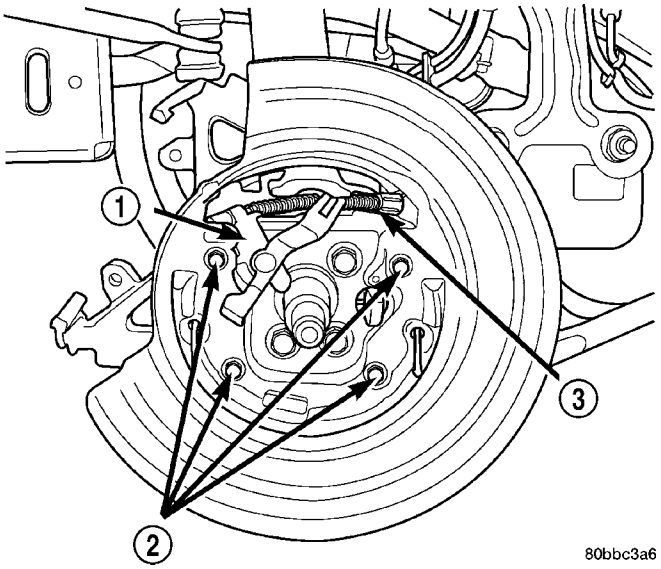

Fig. 11 Parking Brake Actuator Lever

3 - PARKING BRAKE CABLE

AXLE - FRONT WHEEL DRIVE REAR (Continued)

(17) Remove the two bolts on each axle trailing arm securing the cable and routing brackets to the arm (Fig. 13).

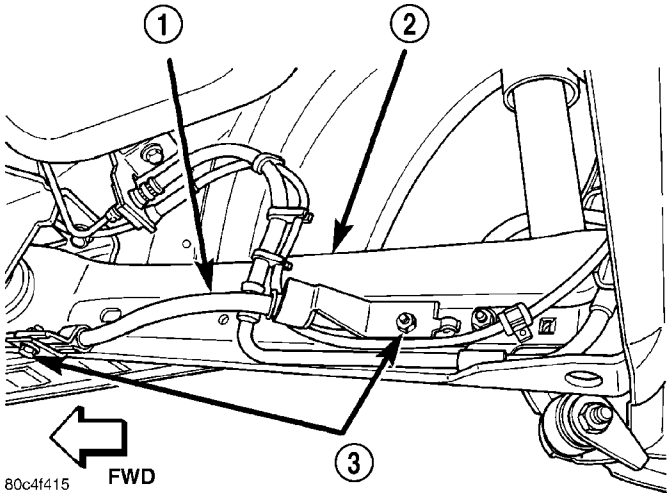

Fig. 13 Cable Routing Bracket Fasteners

1 - CABLE
2 - ARM
3 - FASTENERS

(18) Pull cable through hole in trailing arm.

(19) On vehicles equipped with antilock brakes, remove the bolts securing the wheel speed sensor heads to the disc brake adapters or drum brake support plates (Fig. 14). Remove the sensors from the adapters or support plates.

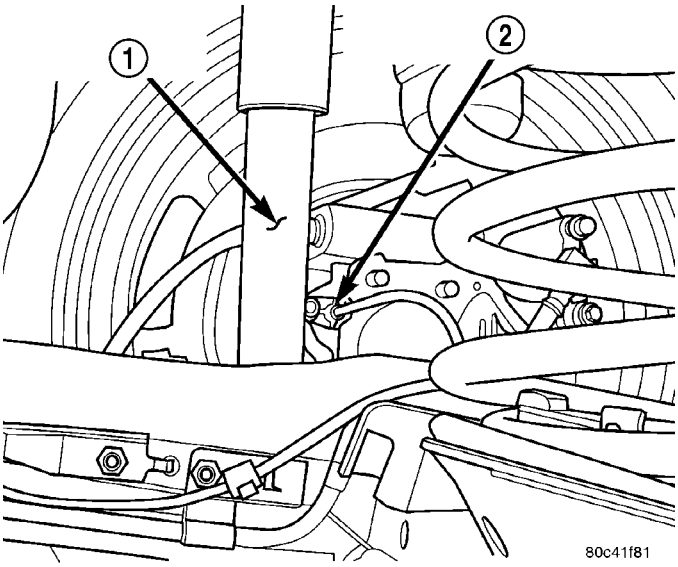

Fig. 14 Wheel Speed Sensor

1 - SHOCK ABSORBER
2 - RIGHT REAR WHEEL SPEED SENSOR

(20) Remove the four bolts securing each brake shoe support plate (drum brakes) or disc brake adapter, and spindle to the axle (Fig. 5).

(21) On each side of the vehicle, remove the support plate or disc brake adapter, and the spindle from the axle. Hang the support plate out of the way using a wire hanger or bungee cord.

(22) Remove the bolt securing the watts link bell crank to the center of the axle (Fig. 15).

(23) If equipped with a rear stabilizer bar, remove the bolts securing the stabilizer bar cushion retainers to the rear axle (Fig. 16), then remove the stabilizer bar from the axle.

(24) Position a transmission jack or equivalent under the center of the axle raising it enough to support the axle.

(25) Remove the shock absorber lower mounting bolts and nuts at the axle (Fig. 15).

(26) Lower the transmission jack until the coil springs can be removed from the axle.

(27) Remove the coil springs and rubber isolators (Fig. 15).

(28) Using an awl, scribe a line marking the location of the axle trailing arm bracket, side-to-side and front-to-rear, on the body of the vehicle (Fig. 17).

(29) Remove the bolts securing the trailing arm forward brackets to the body of the vehicle.

(30) Remove the axle from the vehicle.

(31) To remove the trailing arm forward brackets from the axle, remove the thru-bolts.

INSPECTION

Verify proper torque of all axle fasteners.

Inspect the axle looking for damage or bending. If damage is evident, the axle must be replaced.

Inspect for broken or cracked welds at each end of the twist beam within the axle. Inspect for broken or cracked welds at each axle trailing arm bushing bore. If a problem is present, the axle must be replaced.

Inspect the bushings at the leading ends of the axle trailing arms. Look for damage or deterioration of the bushings. Make sure the bushings are centered side-to-side in their bore. If a problem exists, the bushings must be replaced. They can be replaced separately from the axle.

INSTALLATION

(1) If removed, install the trailing arm forward brackets on each side of the axle in the following way:

(a) From above the axle, place the bracket down over the axle trailing arm bushing aligning the hole in the bracket with the center hole in the bushing (Fig. 15).

(b) From the outboard side of the axle and bracket, push the thru-bolt through the bracket and bushing. **The trailing arm bracket thru-bolts must be installed from the outside, in toward the center of the axle assembly, otherwise the bolt threaded ends will come in contact with the body of the vehicle upon axle installation on vehicle.**

(c) Install the nut on the inboard end of the nut. Tighten the nut until the bracket has resistance when turned, but still moves independent of the axle bushing. It must be fully tightened later, once the vehicle is at curb height.

(2) Center the axle beam on the transmission jack standing at axle removal height.

(3) Swing the trailing arms up aligning the brackets with the scribed marks made upon removal (Fig. 17), then install all eight mounting bolts (four per side). Thread the bolts in, but do not fully tighten.

(4) Tap the axle trailing arm brackets as necessary to align the brackets to the scribed marks, then tighten the bolts to a torque of 54 N·m (40 ft. lbs.).

(5) Install a rubber isolator on each end of the coil springs wrapping the rubber fingers around the coil (Fig. 18). Turn the isolators until the rubber abutment butts up against the flat end of the spring coil.

NOTE: Both ends of the coil spring are identical. Either end of the spring can be the top or bottom.

(6) Place the coil springs on top of the axle spring perches.

(7) The coil springs require proper orientation to the body when installed. To do this, turn the coil springs (along with the rubber isolators) until the flat end of each upper spring coil lines up with an imaginary line running parallel with the axle beam as shown (Fig. 19). Also, make sure that the upper coils end near the outboard sides of the vehicle and not 180 degrees of that location.

AXLE - FRONT WHEEL DRIVE REAR (Continued)

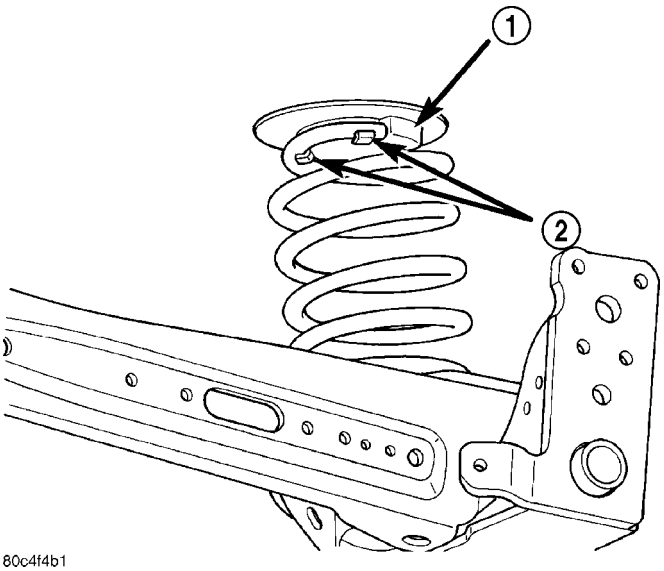

Fig. 18 Isolator Properly Installed

1 - ISOLATOR ABUTMENT
2 - FINGERS

(8) Raise the transmission jack guiding the coil springs into the spring mounting brackets on the body of the vehicle. Raise the jack until the shock absorber lower mounting bolts can be installed though the axle brackets and shock absorber lower mounting eyes (Fig. 15).

(9) Install the washer and nut on the end of each shock absorber lower mounting bolt. Tighten the mounting bolts to a torque of 88 N·m (65 ft. lbs.).

(10) Remove the jack.

(11) If equipped with a rear stabilizer bar, hook the lower ends of the stabilizer bar cushion retainers into the slots in the back of the axle, then rotate the opposite end of the retainers upward so the mounting bolts can be installed. Install the mounting bolt though each cushion retainer into the threads in the rear axle (Fig. 16). Tighten the rear stabilizer bar cushion retainer bolts to a torque of 61 N·m (45 ft. lbs.).

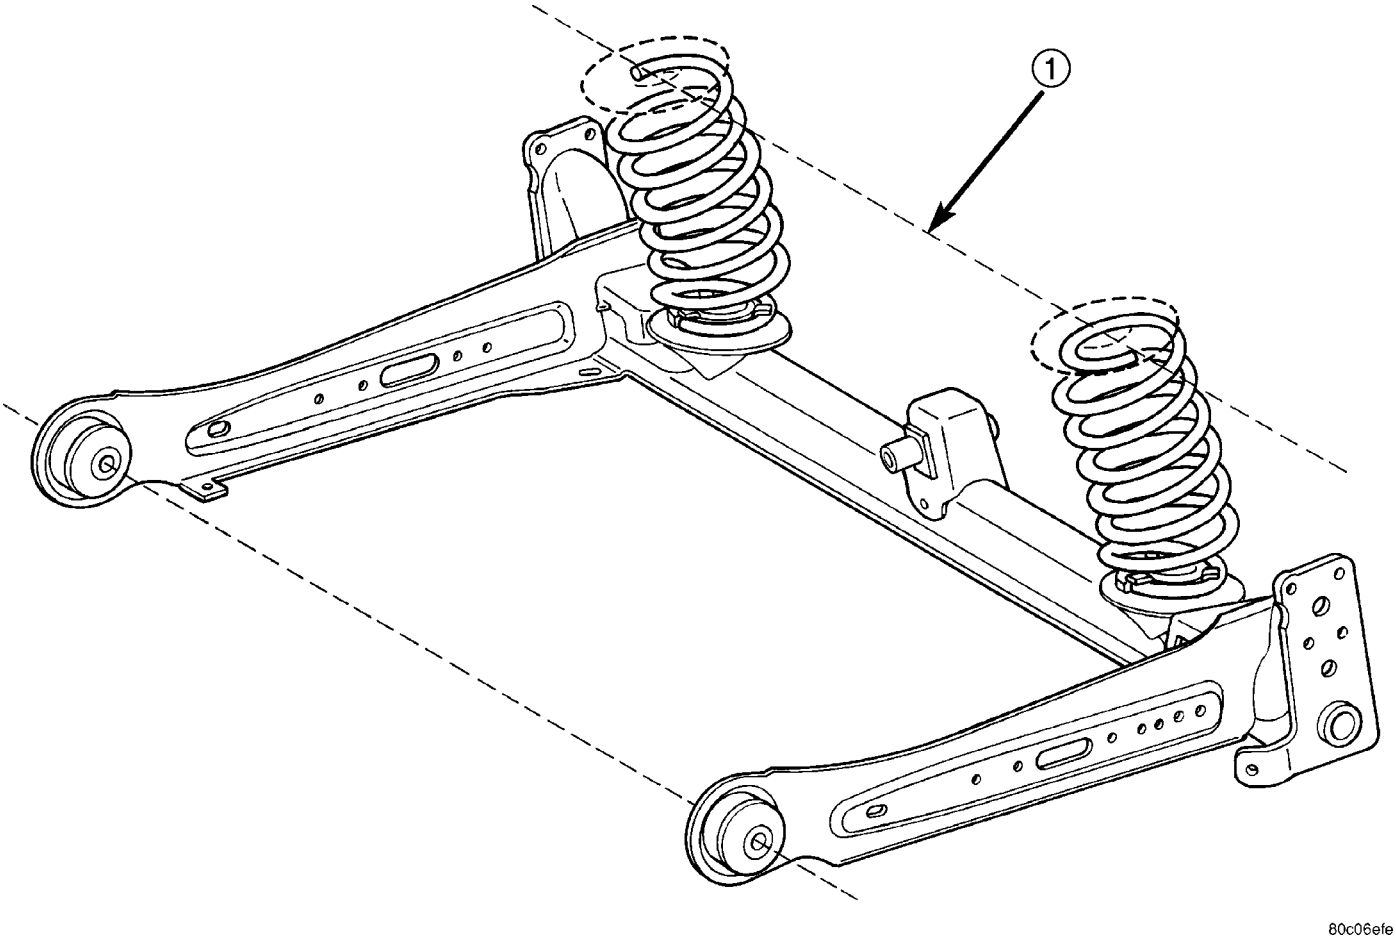

Fig. 19 Coil Spring Orientation

1 - IMAGINARY LINE

AXLE - FRONT WHEEL DRIVE REAR (Continued)

CAUTION: When installing the watts links and bell crank to the axle, make sure the bell crank is right-side-up. When mounted properly, the words "BACK UP" should be able to be read from the rear over the top of the axle (Fig. 20).

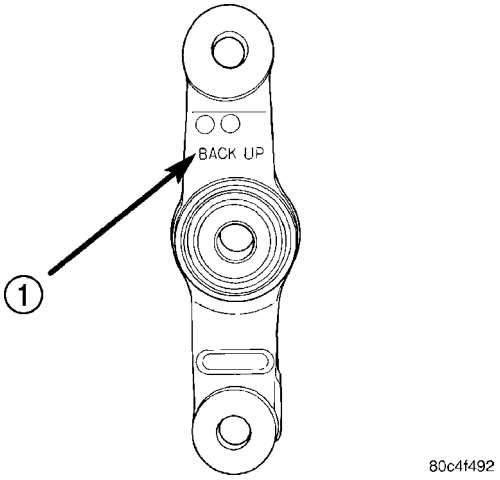

Fig. 20 Bell Crank

1 - INSTALLATION DIRECTION

(12) Install the bolt from the front securing the watts link bell crank to the center of the axle (Fig. 15). Place the washer and nut on the end of the mounting bolt and tighten it to a torque of 149 N·m (110 ft. lbs.).

(13) On each side of the vehicle, Install the spindle and the support plate (drum brakes) or disc brake adapter on the end of the axle (Fig. 5).

(14) Clean the threads of the bolts used to mount the brake shoe support plates or disc brake adapters, and the spindles to the axle, then apply Mopar® Stud & Bearing Mount Adhesive or equivalent to the bolt threads or replace with new mounting bolts.

(15) Install the four bolts securing each brake shoe support plate or disc brake adapter, and the spindle to the axle. Tighten the mounting bolts to a torque of 95 N·m (70 ft. lbs.).

(16) On vehicles equipped with antilock brakes, install the wheel speed sensor heads in the disc brake adapters or drum brake support plates and install the bolts securing them in place (Fig. 14). Tighten the wheel speed sensor mounting bolts to a torque of 12 N·m (105 in. lbs.).

(17) Guide the end of each parking brake cable through hole in the trailing arm towards the brake.

(18) Align the cable routing brackets with their mounts on the trailing arm. Install the two bolts securing the cable and routing brackets to the trailing arm (Fig. 13). Install and tighten the mounting bolts to a torque of 11 N·m (100 in. lbs.).

(19) On each side of the vehicle, install the parking brake cable into the brake support plate or the rear disc brake adapter. Be sure the locking fingers on the cable retainer are expanded once the cable is pushed all the way into the support plate or brake adapter hole to ensure the cable is securely held in place.

(20) On vehicles equipped with rear drum brakes, on each side of the vehicle:

- Install the parking brake cable on the parking brake cable actuating lever (Fig. 8).
- Install the actuating spring to the brake shoe and the brake adjustment lever (Fig. 9).

(21) On vehicles equipped with rear disc brakes, on each side of the vehicle:

- Install the parking brake shoe actuator lever on the parking brake cable (Fig. 11).
- Install the parking brake shoe assemblies on the disc brake adapter (Fig. 7).

(22) Install a hub and bearing on each rear spindle. Install a NEW hub and bearing retaining nut. Tighten the retaining nuts to a torque of 217 N·m (160 ft. lbs.).

(23) Install the hub and bearing dust caps.

NOTE: On vehicles with rear drum brakes, before installing the drum, it may be necessary to adjust the rear brakes. (Refer to 5 - BRAKES/HYDRAULIC/ MECHANICAL/BRAKE PADS/SHOES - ADJUSTMENTS)

(24) On drum brake equipped vehicles, install the brake drums.

(25) On vehicles equipped with rear disc brakes (Fig. 6):

(a) Install the brake rotors.

(b) Install the disc brake calipers.

(c) Install the caliper guide pin bolts, then tighten them to a torque of 22 N·m (192 in. lbs.).

(26) Install the bolts securing the disc brake flex hoses or drum brake flex hoses to the axle trailing arms.

(27) Install the rear tire and wheel assemblies. Tighten all wheel nuts to a torque of 135 N·m (100 ft. lbs.).

(28) Lower the vehicle.

(29) Install the rear parking brake cables into the equalizer on the parking brake lever output cable (Fig. 4).

(30) Ensure that the parking brake cables are correctly installed on the equalizer and aligned with the cable track on the parking brake lever.

AXLE - FRONT WHEEL DRIVE REAR (Continued)

WARNING: THE AUTOMATIC ADJUSTING FEATURE OF THIS PARKING BRAKE LEVER CONTAINS A CLOCKSPRING LOADED TO APPROXIMATELY 19 POUNDS. DO NOT RELEASE THE AUTOMATIC ADJUSTER LOCKOUT DEVICE UNLESS THE REAR PARKING BRAKE CABLES AND EQUALIZER ARE CONNECTED TO THE LEVER OUTPUT CABLE. KEEP HANDS OUT OF AUTOMATIC ADJUSTER SECTOR AND PAWL AREA. FAILURE TO OBSERVE CAUTION IN HANDLING THIS MECHANISM COULD LEAD TO SERIOUS INJURY.

NOTE: The parking brake lever can only be in the released position when releasing the automatic adjuster.

(31) Keeping your hands clear of the automatic adjuster sector and pawl area, firmly grasp the parking brake lever pin punch (drill bit or locking pin if a new mechanism has been installed) (Fig. 3), then quickly remove it from the parking brake lever mechanism. This will allow the parking brake lever mechanism to automatically adjust the parking brake cables.

(32) Cycle the parking brake lever once to position the parking brake cables, then return the parking brake lever its released position.

(33) Check the rear wheels of the vehicle. They should rotate freely without excessive dragging with the lever in its released position.

(34) Install the center console and its mounting screws.

(35) Install the shift knob if previously removed.

(36) Apply the parking brake.

(37) Remove the blocks from the tires and wheels.

(38) Reconnect the battery negative terminal.

(39) Reinstall the air cleaner cover.

(40) Place the vehicle on an alignment rack or drive-on hoist.

(41) With the vehicle at curb height, tighten both trailing arm to mounting bracket pivot thru-bolts to a torque of 122 N·m (90 ft. lbs.).

(42) Check the rear wheel alignment (Refer to 2 - SUSPENSION/WHEEL ALIGNMENT - STANDARD PROCEDURE). If necessary, thrust angle may be adjusted by loosening the axle training arm bracket bolts to the body and shifting the axle forward or rearward, then retightening the bolts to a torque of 54 N·m (40 ft. lbs.).

AXLE PIVOT BUSHING

REMOVAL

NOTE: Before proceeding, (Refer to 2 - SUSPENSION/REAR - WARNING).

(1) Raise the vehicle. (Refer to LUBRICATION & MAINTENANCE/HOISTING - STANDARD PROCEDURE)

(2) Remove both rear tire and wheel assemblies from the vehicle.

(3) Remove the bolts securing the rear brake flex hoses (and wheel speed sensor cable on ABS models) to the vehicle body immediately behind the axle trailing arm forward brackets.

(4) Remove the two bolts on each axle trailing arm securing the parking brake cables and routing brackets to the arm (Fig. 13).

(5) Move the parking brake cables from their mounting positions away from the bottom of the trailing arm pivot bushing and the forward bracket.

(6) Remove the bolt securing the watts link bell crank to the center of the axle (Fig. 15).

(7) Position a transmission jack or equivalent under the center of the axle raising it just enough to support the axle.

(8) Using an awl, scribe a line marking the location of the axle trailing arm bracket, side-to-side and front-to-rear, on the body of the vehicle (Fig. 17).

(9) Remove the bolts securing the trailing arm forward brackets to the body of the vehicle.

(10) Using the lower shock mounts as a pivot point, pry down on the forward end of the trailing arm and place a block of wood between the top of the arm and the body of the vehicle just to the rear of the forward mounting bracket. Be careful not to pinch any hoses or cables.

(11) Remove the pivot thru-bolt securing the forward bracket to the trailing arm.

(12) Place Receiver, Special Tool 8405-1, on Press, Special Tool C-4212F, and tighten the set screw (Fig. 21).

(13) Place the special tool assembly over the bushing to be replaced as shown (Fig. 21). When properly installed, the screw drive on the special tool will be toward the center of the vehicle. Note the curve on the axle trailing arm. This curve prevents the tool from being properly installed in the opposite direction.

(14) Tighten the screw drive, pressing the bushing out of the trailing arm into the receiver.

(15) Remove the tool and the bushing from the trailing arm. Discard the used bushing.

AXLE PIVOT BUSHING (Continued)

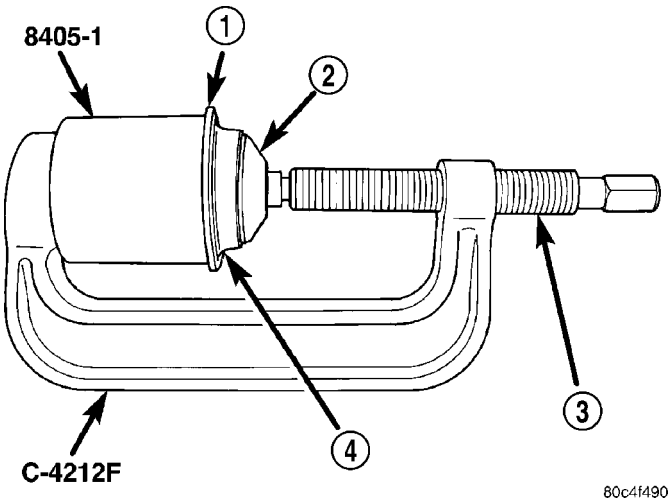

Fig. 21 Bushing Removal

1 - TRAILING ARM
2 - BUSHING
3 - SCREW DRIVE
4 - CURVE

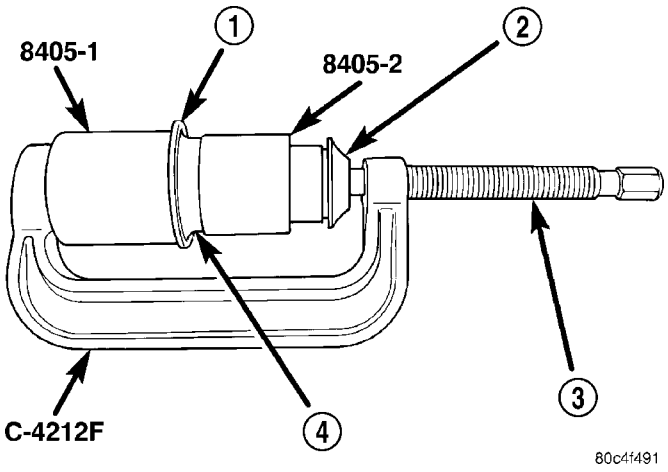

Fig. 22 Bushing Installation

1 - TRAILING ARM
2 - BUSHING
3 - SCREW DRIVE
4 - CURVE

(16) If the opposite side bushing needs to be removed, repeat Step 11 through Step 15 on the opposite bushing.

INSTALLATION

NOTE: To ease and attain proper installation of the bushing using Special Tool 8405, use Mopar® Rubber Bushing Installation Lube as indicated in the following step.

(1) Apply Mopar® Rubber Bushing Installation Lube to the outside edges of the NEW bushing. Also, lubricate the inside of the Installer, Special Tool 8405-2 with the special lube.

(2) Place the stepped end of the Installer on the end of the trailing arm bushing sleeve that has the curved flange at the arm (Fig. 22).

(3) Place the lubricated bushing inside the large opening in the Installer.

(4) Place the Press, Special Tool C-4212F, with Receiver, Special Tool 8405-1, installed, over the arm, Installer and bushing as shown (Fig. 22). When properly installed, the screw drive on the special tool will be toward the center of the vehicle. Note the curve on the axle trailing arm. This curve prevents the tool from being properly installed in the opposite direction.

(5) Tighten the screw drive, pressing the bushing into the trailing arm sleeve. Do not over-install the bushing; the bushing can be pushed out the other side, into the Receiver. Push the bushing in until freed from the installer and centered in the trailing arm sleeve. The outer lips of the bushing must hang out past the end of the sleeve on each side of the trailing arm.

(6) Remove the tools from the trailing arm.

(7) If the opposite side bushing needs to be installed, repeat Step 1 through Step 6 on the opposite side.

(8) Install the trailing arm forward bracket(s) on the axle using the following way:

(a) From above the axle, place the bracket down over the axle trailing arm bushing aligning the hole in the bracket with the center hole in the bushing (Fig. 15).

(b) From the outboard side of the axle and bracket, push the thru-bolt through the bracket and bushing. **The trailing arm bracket thru-bolts must be installed from the outside, in toward the center of the axle assembly, otherwise the bolt threaded ends will come in contact with the body of the vehicle upon axle installation on vehicle.**

(c) Install the nut on the inboard end of the nut. Tighten the nut until the bracket has resistance when turned, but still moves independent of the axle bushing. It must be fully tightened later, once the vehicle is at curb height.

(9) Remove the wood block between the arm and body of the vehicle.

(10) Swing the trailing arms up aligning the brackets with the scribed marks made upon removal (Fig. 17), then install all eight mounting bolts (four per side). Thread the bolts in, but do not fully tighten.

(11) Tap the axle trailing arm brackets as necessary to align the brackets to the scribed marks, then tighten the bolts to a torque of 54 N·m (40 ft. lbs.).

(12) Remove the jack.

AXLE PIVOT BUSHING (Continued)

CAUTION: When installing the watts links and bell crank to the axle, make sure the bell crank is right-side-up. When mounted properly, the words "BACK UP" should be able to be read from the rear over the top of the axle (Fig. 20).

(13) Install the bolt from the front securing the watts link bell crank to the center of the axle (Fig. 15). Place the washer and nut on the end of the mounting bolt and tighten it to a torque of 149 N·m (110 ft. lbs.).

(14) Move the parking brake cables to their original mounting position below the axle pivot bushing on the inboard side of the trailing arm.

(15) Align the cable routing brackets with their mounts on the trailing arm. Install the two bolts securing the cable and routing brackets to the trailing arm (Fig. 13). Install and tighten the mounting bolts to a torque of 11 N·m (100 in. lbs.).

(16) Make sure the parking brake cable and grommet is still in the proper position at the body access hole.

(17) Install the bolts securing the brake flex hoses (and wheel speed sensor cable on ABS models) to the vehicle body immediately behind the axle trailing arm forward brackets.

(18) Install the rear tire and wheel assemblies. Tighten all wheel nuts to a torque of 135 N·m (100 ft. lbs.).

(19) Lower the vehicle.

(20) Place the vehicle on an alignment rack or drive-on hoist.

(21) With the vehicle at curb height, tighten both trailing arm to mounting bracket pivot thru-bolts to a torque of 122 N·m (90 ft. lbs.).

HUB / BEARING

DESCRIPTION

The rear wheel bearing and wheel mounting hub used on this vehicle are a one-piece sealed unit or hub and bearing assembly. It is permanently lubricated when assembled and is sealed for life. There is no periodic lubrication or maintenance recommended for these units.

The hub and bearing is mounted on the spindle which is bolted to the axle (Fig. 23). The hub and bearing is secured to the spindle using a special nut.

Vehicles equipped with antilock brakes have rear hub and bearings with the tone wheel for the rear wheel speed sensors pressed onto the hub.

The only serviceable components of the hub and bearing are the wheel mounting studs pressed into the hub.

OPERATION

The hub and bearing adapts the tire and wheel assembly to the axle mounted spindle. It's bearing allows the tire and wheel assembly to rotate freely on the vehicle. The brake drum or brake rotor mounts to the hub's wheel mounting studs aiding in stopping the vehicle when required.

On vehicles equipped with antilock brakes, the tone wheel pressed onto the hub allows the brake system to sense wheel motion.

DIAGNOSIS AND TESTING - HUB AND BEARING (REAR)

The hub and bearing is designed for the life of the vehicle and requires no type of periodic maintenance. The following procedure may be used for diagnosing the condition of the hub and bearing.

With the wheel, disc brake rotor or brake drum removed, rotate the hub. Any roughness or resistance to rotation may indicate dirt intrusion or a failed hub bearing. If the bearing exhibits any of these conditions during diagnosis, the hub and bearing will require replacement. The bearing is not serviceable alone.

Damaged bearing seals and the resulting excessive grease loss may also require hub and bearing replacement. Moderate grease weapage from the bearing is considered normal and should not require replacement of the wheel bearing.

To diagnose a bent hub, refer to ROTOR in BRAKES for the procedure on measuring hub runout.

REMOVAL

NOTE: Before proceeding, (Refer to 2 - SUSPENSION/REAR - WARNING).

(1) Raise the vehicle. (Refer to LUBRICATION & MAINTENANCE/HOISTING - STANDARD PROCEDURE)

(2) Remove the rear tire and wheel assembly.

(3) On vehicles equipped with rear drum brakes, remove the brake drum retaining clips, then the drum (Fig. 23).

(4) On vehicles equipped with rear disc brakes:

(a) Remove the disc brake caliper guide pin bolts, then the caliper from the disc brake adapter (Fig. 24).

(b) Hang the caliper out of the way using a wire hanger or bungee cord.

(c) Remove the brake rotor retaining clips (Fig. 23).

(d) Remove the brake rotor from the rear hub and bearing.

2 - GUIDE PIN BOLTS
3 - HUB AND BEARING
4 - BRAKE ROTOR
5 - RETAINER CLIP
6 - DUST CAP
7 - NUT
8 - DISC BRAKE CALIPER

(5) Remove the dust cap from the hub and bearing (Fig. 23).

(6) Remove the hub and bearing retaining nut from the spindle, then remove the hub and bearing (Fig. 23).

INSTALLATION

(1) Install the hub and bearing on the spindle (Fig. 23). Install a NEW hub and bearing retaining nut. Tighten the retaining nuts to a torque of 217 N·m (160 ft. lbs.).

(2) Install the hub and bearing dust caps.

(3) On drum brake equipped vehicles, install the brake drum.

(4) On vehicles equipped with rear disc brakes (Fig. 24):

(a) Install the brake rotor.

(b) Install the disc brake caliper.

(c) Install the caliper guide pin bolts, then tighten them to a torque of 22 N·m (192 in. lbs.).

(5) Install the rear tire and wheel assembly. Tighten all wheel nuts to a torque of 135 N·m (100 ft. lbs.).

(6) Lower the vehicle.

JOUNCE BUMPER

REMOVAL

(1) Raise the vehicle. (Refer to LUBRICATION & MAINTENANCE/HOISTING - STANDARD PROCEDURE)

(2) Grasp the jounce bumper and with a twisting motion, remove the jounce bumper from the bracket mounted to the body.

INSTALLATION

CAUTION: Do not use any type of lubricant to aid in jounce bumper installation. Premature jounce bumper failure issues could result.

(1) Carefully twist and push the jounce bumper into the bracket mounted to the body of the vehicle until it bottoms in the bracket.

(2) Lower the vehicle.

SHOCK ABSORBER

DESCRIPTION

There is one gas-charged shock absorber on each side of the rear suspension (Fig. 25). The top of each shock absorber is bolted to a bracket attached to the body of the vehicle. The bottom of each shock absorber is bolted to the rear axle.

DIAGNOSIS AND TESTING - SHOCK ABSORBER

Inspect the shock absorber for damage and evidence of fluid running from the upper end of the fluid reservoir. (Actual leakage will be a stream of fluid running down the side of the reservoir tube and dripping off lower end of unit). A slight amount of seepage between the shaft and shaft seal is not unusual and does not affect performance of the shock absorber.

REMOVAL

NOTE: Before proceeding, (Refer to 2 - SUSPENSION/REAR - WARNING).

(1) Raise the vehicle. (Refer to LUBRICATION & MAINTENANCE/HOISTING - STANDARD PROCEDURE)

(2) Remove the tire and wheel assembly.

(3) Position a transmission jack or equivalent under the center of the axle raising it enough to support the axle.

(4) Remove the shock absorber lower mounting bolt and nut at the axle (Fig. 25).

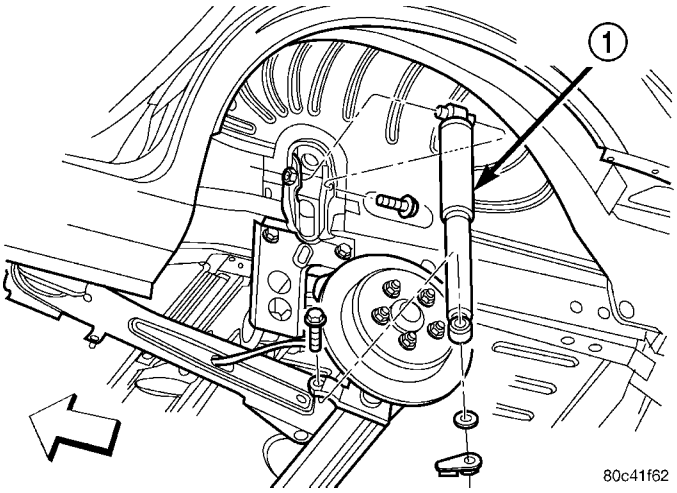

Fig. 25 Shock Absorber Mounting

1 - SHOCK ABSORBER

(5) Remove the upper mounting bolt (Fig. 25), then remove the shock absorber from the vehicle.

INSTALLATION

(1) Install the shock absorber to the vehicle by first attaching the top shock absorber eye to the body bracket using the upper mounting bolt (Fig. 25). Do not fully tighten the bolt at this time.

(2) Raise or lower the jack as necessary until the shock absorber lower mounting bolt can be installed though the axle flange and the shock absorber lower mounting eye (Fig. 25).

(3) Install the washer and nut on the end of the shock absorber lower mounting bolt. Tighten the lower mounting bolt to a torque of 88 N·m (65 ft. lbs.).

(4) Tighten the upper shock absorber mounting bolt to a torque of 99 N·m (73 ft. lbs.).

(5) Remove the jack.

(6) Install the tire and wheel assembly. Tighten all wheel nuts to a torque of 135 N·m (100 ft. lbs.).

(7) Lower the vehicle.

SPINDLE

REMOVAL

NOTE: Before proceeding, (Refer to 2 - SUSPENSION/REAR - WARNING).

(1) Raise the vehicle. (Refer to 2 - SUSPENSION/REAR - WARNING)

(2) Remove the rear tire and wheel assembly.

(3) On vehicles equipped with rear drum brakes:

(a) Remove the bolts securing the drum brake flex hose to the axle trailing arm.

(b) Remove the brake drum retaining clips, then the drum (Fig. 26).

SPINDLE (Continued)

(4) On vehicles equipped with rear disc brakes:

(a) Remove the bolts securing the disc brake flex hose to the axle trailing arm.

(b) Remove the disc brake caliper guide pin bolts, then the caliper from the disc brake adapter (Fig. 27).

(c) Hang the caliper out of the way using a wire hanger or bungee cord.

(d) Remove the brake rotor from the rear hub and bearing.

(5) Remove the dust cap from the rear hub and bearing (Fig. 26).

(6) Remove the hub and bearing retaining nut from the spindle, then remove the hub and bearing (Fig. 26).

(7) Remove the two bolts on each axle trailing arm securing the parking brake cable and routing brackets to the axle trailing arm (Fig. 28).

(8) On vehicles equipped with antilock brakes, remove the bolt securing the wheel speed sensor to the disc brake adapter (Fig. 29). Remove the sensor from the adapter.

(9) Remove the four bolts securing the brake shoe support plate (drum brakes) or disc brake adapter, and spindle to the axle (Fig. 26).

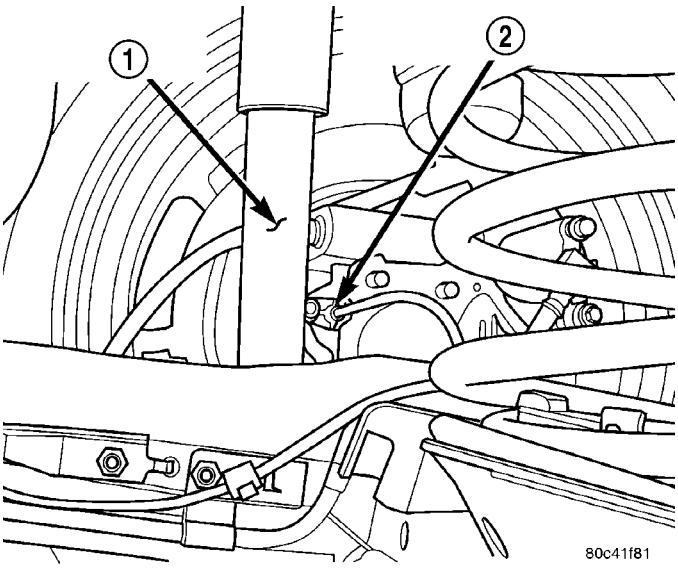

Fig. 29 Wheel Speed Sensor

1 - SHOCK ABSORBER
2 - RIGHT REAR WHEEL SPEED SENSOR

(10) Move the support plate or disc brake adapter away from the axle. At the same time, loosen the spindle from the axle and remove it from the back of the support plate or disc brake adapter.

INSTALLATION

(1) Place a new seal on the spindle (Fig. 26).

(2) Install the spindle from the back side into the support plate (drum brakes) or disc brake adapter, then place it into its mounting position on the end of the axle (Fig. 26).

NOTE: When performing the following step, use new mounting bolts or clean and apply Mopar® Stud & Bearing Mount Adhesive or equivalent to the original mounting bolt threads before reuse.

(3) Place the support plate (drum brakes) or disc brake adapter up against the spindle, then install the four bolts securing the brake shoe support plate or disc brake adapter, and the spindle to the axle. Tighten the mounting bolts to a torque of 95 N·m (70 ft. lbs.).

(4) On vehicles equipped with antilock brakes, install the wheel speed sensor in the disc brake adapter and install the bolt securing it in place (Fig. 29). Tighten the wheel speed sensor mounting bolt to a torque of 12 N·m (105 in. lbs.).

(5) Align the parking brake cable routing brackets with their mounts on the trailing arm. Install the two bolts securing the cable and routing brackets to the trailing arm (Fig. 28). Install and tighten the mounting bolts to a torque of 11 N·m (100 in. lbs.).

(6) Install the hub and bearing on the spindle (Fig. 26). Install a NEW hub and bearing retaining nut. Tighten the retaining nut to a torque of 217 N·m (160 ft. lbs.).

(7) Install the hub and bearing dust cap.

NOTE: On vehicles with rear drum brakes, before installing the drum, it may be necessary to adjust the rear brakes. (Refer to 5 - BRAKES/HYDRAULIC/ MECHANICAL/BRAKE PADS/SHOES - ADJUSTMENTS)

(8) On drum brake equipped vehicles, install the brake drum.

(9) On vehicles equipped with rear disc brakes (Fig. 27):

(a) Install the brake rotor.

(b) Install the disc brake caliper.

(c) Install the caliper guide pin bolts, then tighten them to a torque of 22 N·m (192 in. lbs.).

(10) Install the bolts securing the disc brake flex hose or drum brake flex hose to the axle trailing arm.

(11) Install the rear tire and wheel assembly. Tighten all wheel nuts to a torque of 135 N·m (100 ft. lbs.).

(12) Lower the vehicle.

SPRING

DESCRIPTION

The springs used on the rear suspension of this vehicle are the coil type (Fig. 30). They are mounted straight above the rear axle beam in line with the rear wheels. A spring isolator is attached to each end of the coil springs. Coil springs come in various heights, be sure the correct spring is in use.

REMOVAL

NOTE: Before proceeding, (Refer to 2 - SUSPENSION/REAR - WARNING).

(1) Raise the vehicle. (Refer to LUBRICATION & MAINTENANCE/HOISTING - STANDARD PROCEDURE)

(2) Remove both rear tire and wheel assemblies from the vehicle.

(3) Remove the bolt securing the watts link bell crank to the center of the axle (Fig. 30).

(4) If equipped with a rear stabilizer bar, remove the bolts securing the stabilizer bar cushion retainers to the rear axle (Fig. 31), then remove the stabilizer bar from the axle.

(5) Position a transmission jack or equivalent under the center of the axle raising it enough to support the axle.

(6) Remove the shock absorber lower mounting bolts and nuts at the axle (Fig. 30).

(7) Lower the transmission jack until the coil springs can be removed from the axle.

(8) Remove the coil springs and rubber isolators (Fig. 30).

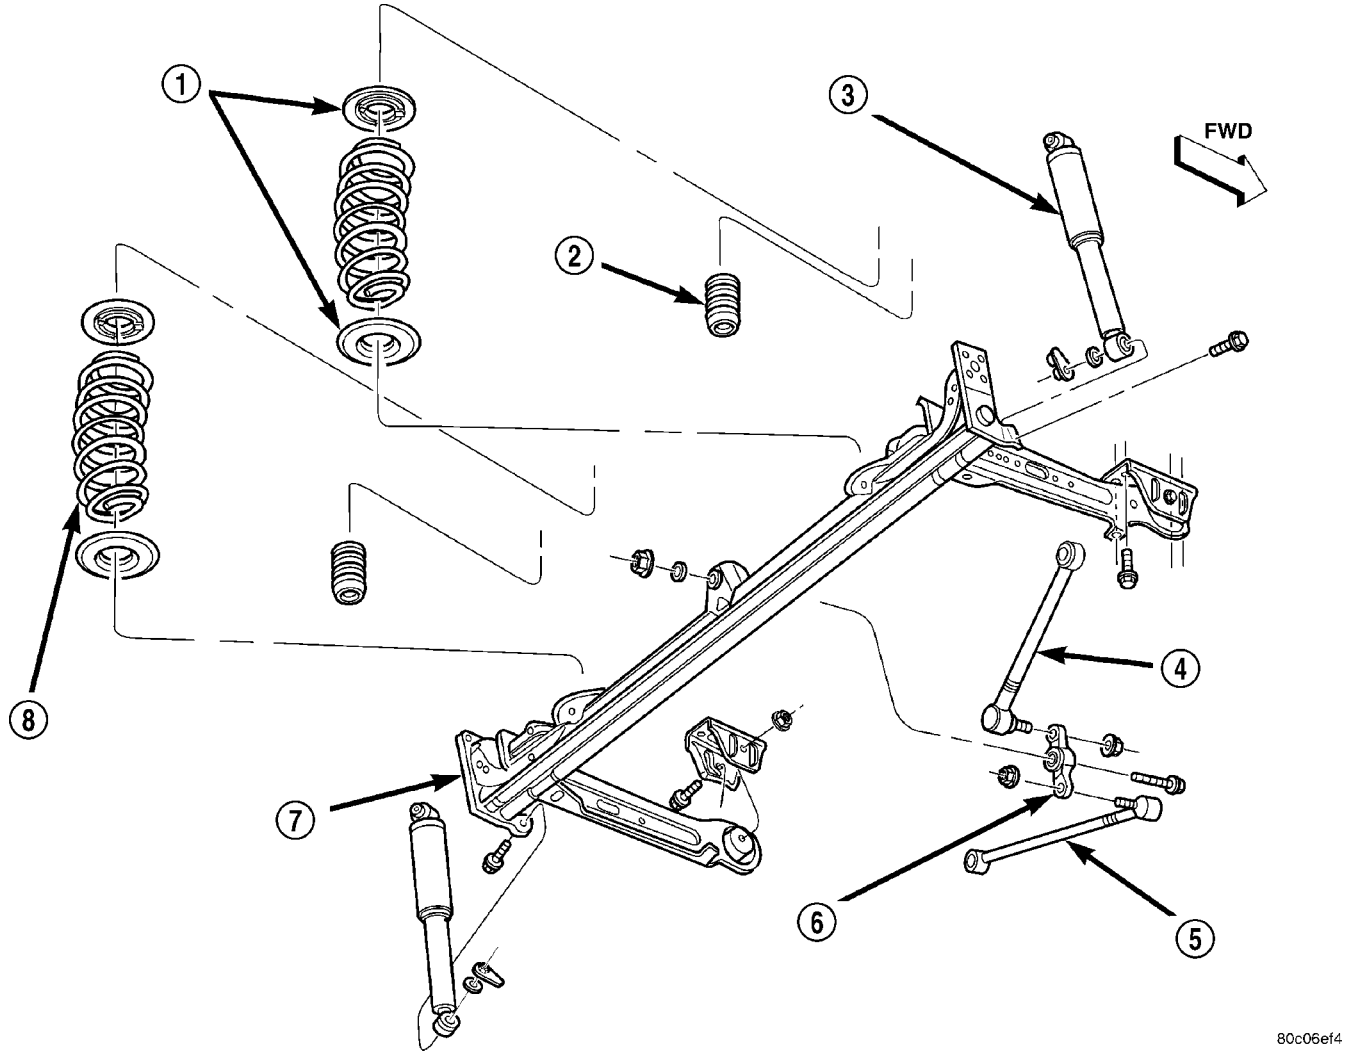

Fig. 30 Rear Suspension

8 - COIL SPRING

SPRING (Continued)

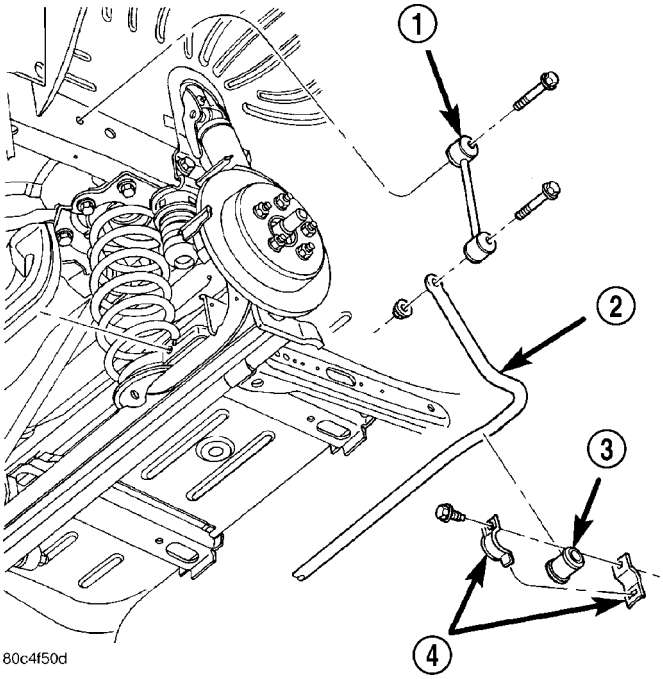

Fig. 31 Stabilizer Bar Mounting

1 - LINK
2 - STABILIZER BAR
3 - CUSHION
4 - RETAINER

INSTALLATION

(1) Install a rubber isolator on each end of the coil springs wrapping the rubber fingers around the coil (Fig. 32). Turn the isolators until the rubber abutment butts up against the flat end of the spring coil.

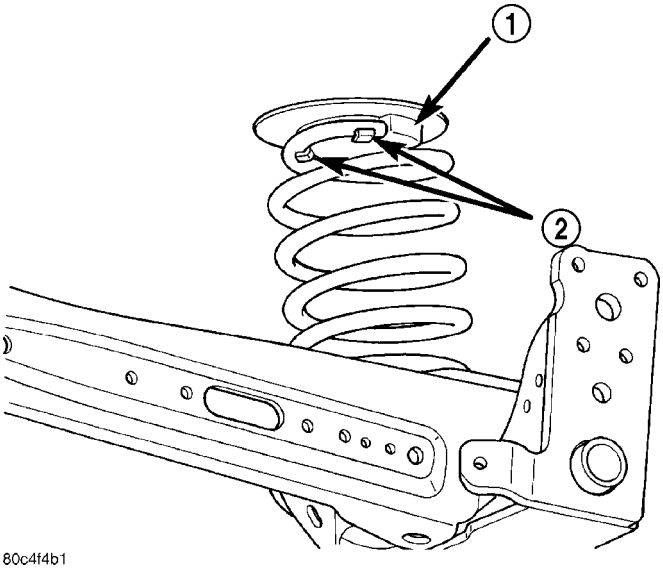

Fig. 32 Isolator Properly Installed

1 - ISOLATOR ABUTMENT
2 - FINGERS

NOTE: Both ends of the coil spring are identical. Either end of the spring can be the top or bottom.

(2) Place the coil springs on top of the axle spring perches.

(3) The coil springs require proper orientation to the body when installed. To do this, turn the coil springs (along with the rubber isolators) until the flat end of each upper spring coil lines up with an imaginary line running parallel with the axle beam as shown (Fig. 33). Also, make sure that the upper coils end near the outboard sides of the vehicle and not 180 degrees of that location.

(4) Raise the transmission jack guiding the coil springs into the spring mounting brackets on the body of the vehicle. Raise the jack until the shock absorber lower mounting bolts can be installed though the axle brackets and shock absorber lower mounting eyes (Fig. 30).

(5) Install the washer and nut on the end of each shock absorber lower mounting bolt. Tighten the mounting bolts to a torque of 88 N·m (65 ft. lbs.).

(6) Remove the jack.

(7) If equipped with a rear stabilizer bar, hook the lower ends of the stabilizer bar cushion retainers into the slots in the back of the axle, then rotate the opposite end of the retainers upward so the mounting bolts can be installed. Install the mounting bolt though each cushion retainer into the threads in the rear axle (Fig. 31). Tighten the rear stabilizer bar cushion retainer bolts to a torque of 61 N·m (45 ft. lbs.).

CAUTION: When installing the watts links and bell crank to the axle, make sure the bell crank is right-side-up. When mounted properly, the words "BACK UP" should be able to be read from the rear over the top of the axle (Fig. 34).

(8) Install the bolt from the front securing the watts link bell crank to the center of the axle (Fig. 30). Place the washer and nut on the end of the mounting bolt and tighten it to a torque of 149 N·m (110 ft. lbs.).

(9) Install the rear tire and wheel assemblies. Tighten all wheel nuts to a torque of 135 N·m (100 ft. lbs.).

(10) Lower the vehicle.

(11) Verify proper vehicle curb height. (Refer to 2 - SUSPENSION/WHEEL ALIGNMENT - STANDARD PROCEDURE)

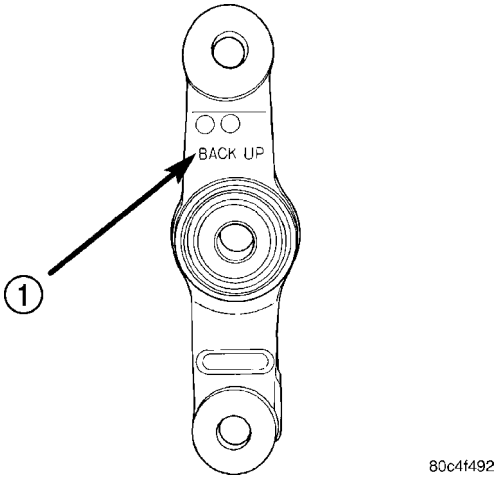

Fig. 34 Bell Crank

1 - INSTALLATION DIRECTION

STABILIZER BAR

DESCRIPTION

Some versions of this vehicle are equipped with a rear stabilizer bar. The stabilizer bar interconnects the rear axle with the frame rails of the vehicle (Fig. 35).

Attachment of the stabilizer bar to the rear frame rails of the vehicle is through 2 rubber-isolator stabilizer bar links. The stabilizer bar attachment to the axle is done utilizing two rubber isolated cushions and retainers.

OPERATION

Jounce and rebound movements affecting one side of the rear suspension are partially transmitted to the opposite side of the rear suspension to stabilize body roll.

STABILIZER BAR (Continued)

REMOVAL

NOTE: Before proceeding, (Refer to 2 - SUSPENSION/REAR - WARNING).

(1) Raise the vehicle. (Refer to LUBRICATION & MAINTENANCE/HOISTING - STANDARD PROCEDURE)

(2) Remove both rear wheel and tire assemblies from the vehicle.

(3) Remove the nut from the end of each rear stabilizer bar link bolt fastening the bar to the link (Fig. 35). Pull the bolt out far enough to free the stabilizer bar.

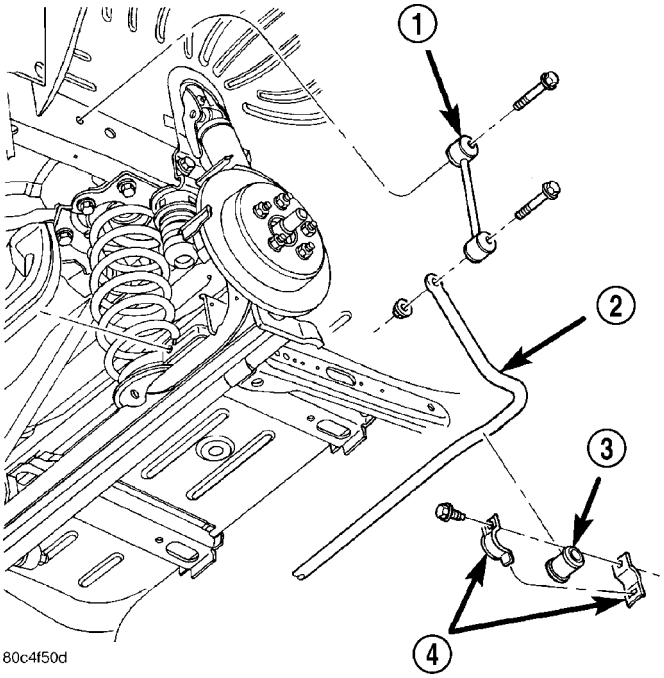

Fig. 35 Bar And Link Mounting (Right Side Shown)

1 - LINK
2 - STABILIZER BAR
3 - CUSHION
4 - RETAINER

(4) While holding the rear stabilizer bar, remove the bolts securing the cushion retainers to the rear axle, then remove the cushion retainers, cushions and stabilizer bar from the vehicle as an assembly.

(5) To remove the cushions from the stabilizer bar, refer to stabilizer bar cushions found in this section.

INSTALLATION

(1) To install the cushions and retainers on the stabilizer bar, refer to stabilizer bar cushions found in this section.

(2) Install the stabilizer bar, cushions and retainers on the vehicle as an assembly.

(3) Hook the lower ends of the cushion retainers in the slot in the back of the axle, then rotate the opposite end of the retainers upward so the mounting bolts can be installed. Install the mounting bolt though each cushion retainer, into the threads in the rear axle (Fig. 35). Tighten the rear stabilizer bar cushion retainer bolts at the axle to a torque of 61 N·m (45 ft. lbs.).

(4) Install each stabilizer bar link bolt and nut attaching the ends of the stabilizer bar to the links (Fig. 35). Do not tighten the bolt and nut at this time.

(5) Install both tire and wheel assemblies on the vehicle. Tighten the wheel mounting stud nuts in proper sequence until all nuts are torqued to half specification. Repeat the tightening sequence, this time, to full specified torque of 135 N·m (100 ft. lbs.).

(6) Lower the vehicle to ground level (curb height).

(7) Tighten the stabilizer bar link bolts and nuts to a torque of 65 N·m (48 ft. lbs.).

STABILIZER BAR CUSHIONS

REMOVAL

NOTE: Before proceeding, (Refer to 2 - SUSPENSION/REAR - WARNING).

(1) Remove the rear stabilizer bar from the axle (Refer to 2 - SUSPENSION/REAR/STABILIZER BAR - REMOVAL).

(2) Bend back the crimp tab at the top of the retainer which secures the two halves of each cushion retainer together. Remove the retainer halves (Fig. 35).

(3) The cushions can be removed from the bar utilizing the preformed slit in each cushion and peeling them off the bar.

INSTALLATION

(1) Install the cushions on the stabilizer bar by opening the slit in each cushion and wrapping it around the bar. When installed properly, the slit in the cushion should face toward the front of the car once the bar is installed.

(2) Perform the following on each stabilizer bar retainer:

(a) Hook the lower end of each retainer halve to the other (Fig. 35).

(b) Install the two halves of the retainer over the cushions, matching the contour of each retainer with its cushion. The slit in the cushion should face straight toward the forward halve of the retainer.

(c) Fold the crimp tab on the forward retainer halve over the rear halve crimping the two halves together.

STABILIZER BAR CUSHIONS (Continued)

(3) Install the stabilizer bar on the rear axle. (Refer to 2 - SUSPENSION/REAR/STABILIZER BAR - INSTALLATION)

STABILIZER BAR LINK

REMOVAL

NOTE: Before proceeding, (Refer to 2 - SUSPENSION/REAR - WARNING).

(1) Raise the vehicle. (Refer to LUBRICATION & MAINTENANCE/HOISTING - STANDARD PROCEDURE)

(2) Remove the appropriate rear wheel and tire assembly from the vehicle.

(3) Remove the nut and bolt from the lower end of the stabilizer bar link attaching it to the stabilizer bar (Fig. 35).

(4) Remove the bolt retaining the link to the rear frame rail (Fig. 35), then remove the stabilizer bar link from the vehicle.

INSTALLATION

(1) Reinstall stabilizer bar link, starting the bolt retaining the link to frame rail (Fig. 35). Do not tighten the bolt at this time.

(2) Install the lower bolt and nut attaching the stabilizer bar link to the stabilizer bar (Fig. 35). Do not tighten the bolt and nut at this time.

(3) Install tire and wheel assembly on the vehicle. Tighten the wheel mounting stud nuts in proper sequence until all nuts are torqued to half specification. Repeat the tightening sequence, this time, to full specified torque of 135 N·m (100 ft. lbs.).

(4) Lower the vehicle to ground level (curb height).

(5) Tighten the stabilizer bar link upper bolt and lower nut to a torque of 65 N·m (48 ft. lbs.).

WATTS LINK ASSEMBLY

DESCRIPTION

The watts link assembly consists of a bell crank mounted to the rear axle and two links extending from the bell crank to brackets mounted to the body of the vehicle (Fig. 37).

The cast iron bell crank has a non—serviceable sealed—for—life bearing mounted in the center of it through which it is fastened to the axle. It also has the words “BACK UP” cast into one side of it indicating the installation direction when mounted to the axle (Fig. 36). Although the pivot may look identical end to end, it is not and must be installed with the words “BACK UP” toward the back of the vehicle facing upright in order to avoid premature bearing failure.

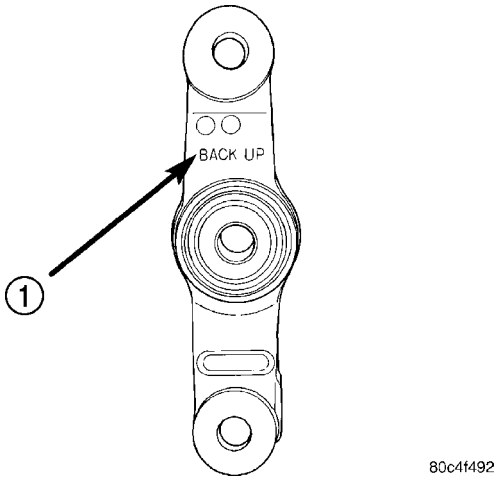

Fig. 36 Bell Crank

1 - INSTALLATION DIRECTION

The upper and lower links both have ball joints on one end and bushings on the other. The ball joint ends connect to the bell crank and the bushing ends connect to a bracket on the body. The upper link extends from the upper hole machined into the bell crank to the bracket on the right side of the vehicle. The lower link extends from the lower hole machined into the bell crank to the bracket on the left side of the vehicle. Although the links look like outer tie rods, no attempt should be made to adjust them. They are fixed to a set length at the factory and require no maintenance. The bushings on the links are not serviceable.

OPERATION

The watts link assembly serves the same purpose as a track bar. That is, it is used to control rear axle lateral movement and provides cross-car location of the axle. Unlike a track bar, the watts link assembly offers more consistent handling and stability at varying suspension heights, either lightly loaded or fully laden. As the suspension lowers or raises, the watts link assembly compensates by rotating the bell crank in the desired direction. This rotation simulates shortening or lengthening of the links. Since there is one link on each side, the change affects each side of the suspension evenly.

DIAGNOSIS AND TESTING - WATTS LINK ASSEMBLY

Inspect each link looking for signs of contact with an object that has caused damage to the link. If a link is bent or damaged, replace it. Do not attempt to repair or straighten a watts link.

WATTS LINK ASSEMBLY (Continued)

Verify there is not excessive play in the ball joint end of each link. Check to make sure the ball joint boots are not torn. Verify the stakes are tightly securing the ball joint forging to the link. Replace the links as necessary. Do not attempt to remove the ball joint from a link or re-stake it. Although it may appear so, the ball joints cannot be serviced separately from the watts links.

Inspect the link bushings for signs of damage or deterioration. If damage or deterioration is present, replace the link. The isolator bushings cannot be serviced separately.

Verify the bell crank is installed properly. From the rear of the vehicle, the words “BACK UP” should be able to be read on the upper half of the bell crank extending above the axle. If not, remove the bell crank and remount it correctly. If the bell crank is not correctly mounted, the watts link assembly will not operate properly.

Inspect the bell crank for signs of damage. Inspect for excessive play in the bearing. With the links disconnected, rotate the bell crank. Any roughness or resistance to rotate may indicate dirt intrusion or a failed bearing. If the bell crank exhibits any of these conditions, replace the bell crank.

WATTS BELL CRANK

REMOVAL

NOTE: Before proceeding, (Refer to 2 - SUSPENSION/REAR - WARNING).

(1) Raise the vehicle. (Refer to LUBRICATION & MAINTENANCE/HOISTING - STANDARD PROCEDURE)

(2) Remove the nut securing the bell crank pivot bolt in the center of the axle (Fig. 37).

(3) With the bolt still installed, slide the bell crank away from the axle just enough to remove the nuts securing both links to the bell crank (Fig. 37). Remove the nuts.

(4) Install the Remover, Special Tool MB991113, on each link ball joint at the bell crank and release ball joint from the bell crank.

(5) Remove the pivot bolt and bell crank from the vehicle.

INSTALLATION

(1) Install the pivot bolt through the front of the watts link bell crank (Fig. 37). Make sure the words “BACK UP” are towards the rear (Fig. 38).

(2) Start the pivot bolt with the bell crank attached into the front of the axle center mounting hole (Fig. 37).

CAUTION: Although both ends of the bell crank appear to be the same, they are not. When installing the watts links and bell crank, make sure the bell crank is properly positioned. When mounted properly, the words “BACK UP” should be able to be read from the rear over the top of the axle (Fig. 38).

NOTE: The upper link extends from the right side of the vehicle to the upper end of the bell crank while the lower link extends from the left side of the vehicle to the lower end of the bell crank.

(3) Install the upper and lower links to the bell crank (Fig. 37). Install the nuts on the ball joint studs and tighten them to a torque of 14 N·m (10 ft. lbs.) plus an additional 180° turn after torque is met.

(4) Slide the bell crank pivot bolt all the way through the axle.

(5) Place the washer and nut on the end of the pivot bolt and tighten it to a torque of 149·m (110 ft. lbs.).

(6) Verify the words “BACK UP” can be read on the bell crank from the rear over the top of the axle.

(7) Lower the vehicle to the ground.

WATTS BELL CRANK (Continued)

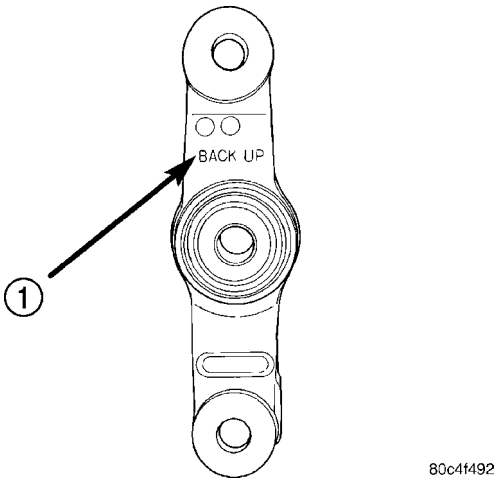

Fig. 38 Bell Crank

1 - INSTALLATION DIRECTION

WATTS LINK

REMOVAL

NOTE: Before proceeding, (Refer to 2 - SUSPENSION/REAR - WARNING).

(1) Raise the vehicle. (Refer to LUBRICATION & MAINTENANCE/HOISTING - STANDARD PROCEDURE)

(2) If the lower watts link is being removed, perform the following first, otherwise proceed to the next step.

(a) Remove the nut securing the bell crank pivot bolt in the center of the axle (Fig. 37).

(b) With the bolt still installed, slide the bell crank away from the axle just enough to remove the nut securing the lower link to the bell crank (Fig. 37).

(3) Remove the nut securing the ball joint to the bell crank (Fig. 37).

(4) Install the Remover, Special Tool MB991113, on the link ball joint at the bell crank and release ball joint from the bell crank.

(5) Remove the bolt securing the link to the bracket on the body of the vehicle. Remove the link.

INSTALLATION

CAUTION: When installing the link, DO NOT attempt to turn the ball joint end of the link independently.

(1) Making sure the ball joint end is positioned properly for mounting to the bell crank (Fig. 37), install the link into the bracket on the body of the vehicle.

(2) Install the bolt (and flag nut for upper link) securing the link to the bracket, but do not fully tighten it at this time. It must be tightened when the vehicle is at curb height.

NOTE: The upper link extends from the right side of the vehicle to the upper end of the bell crank while the lower link extends from the left side of the vehicle to the lower end of the bell crank.

(3) Install the upper or lower link to the bell crank (Fig. 37). Install the nut on the ball joint stud and tighten it to a torque of 14 N·m (10 ft. lbs.) plus an additional 180° turn after torque is met.

(4) If the lower link is the link being installed, perform the following, otherwise proceed to the next step.

(a) Slide the bell crank pivot bolt all the way through the axle.

(b) Place the washer and nut on the end of the pivot bolt and tighten it to a torque of 149 N·m (110 ft. lbs.).

CAUTION: Although both ends of the bell crank appear to be the same, they are not. When installing the watts links or bell crank, make sure the bell crank is properly positioned. When mounted properly, the words “BACK UP” should be able to be read from the rear over the top of the axle (Fig. 38).

(5) Verify the words “BACK UP” can be read on the bell crank from the rear over the top of the axle (Fig. 38). If they cannot be read at this position, the link or bell crank is not installed properly and must be removed and reinstalled so that the words “BACK UP” can be read on the upper rear of the bell crank once installed.

(6) Lower the vehicle to the ground.

(7) Place the vehicle on an alignment rack or drive-on hoist.

(8) With the suspension at curb height, tighten the link mounting bolt at the body bracket to a torque of 92 N·m (68 ft. lbs.).

WHEEL ALIGNMENT 61

WHEEL ALIGNMENT

DESCRIPTION - WHEEL ALIGNMENT

Vehicle wheel alignment is the positioning of all interrelated front and rear suspension angles. These angles affect the handling and steering of the vehicle when it is in motion. Proper wheel alignment is essential for efficient steering, good directional stability, and proper tire wear.

The method of checking a vehicle's front and rear wheel alignment varies depending on the manufacturer and type of equipment used. The manufacturer's instructions should always be followed to ensure accuracy of the alignment, except when DaimlerChrysler Corporation's wheel alignment specifications differ.

On this vehicle, the suspension angles that can be adjusted are as follows:

Front
- Camber
- Toe

Rear
- Camber
- Toe

Check the wheel alignment and make all wheel alignment adjustments with the vehicle standing at its proper curb height specification. Curb height is the normal riding height of the vehicle. It is measured from a certain point on the vehicle to the ground or a designated area while the vehicle is sitting on a flat, level surface. Refer to Curb Height Measurement in this section for additional information.

Typical wheel alignment angles and measurements are described in the following paragraphs.

CAMBER

Camber is the inward or outward tilt of the top of the tire and wheel assembly (Fig. 1). Camber is measured in degrees of angle relative to a true vertical line. Camber is a tire wearing angle.

- Excessive negative camber will cause tread wear at the inside of the tire.
- Excessive positive camber will cause tread wear on the outside of the tire.

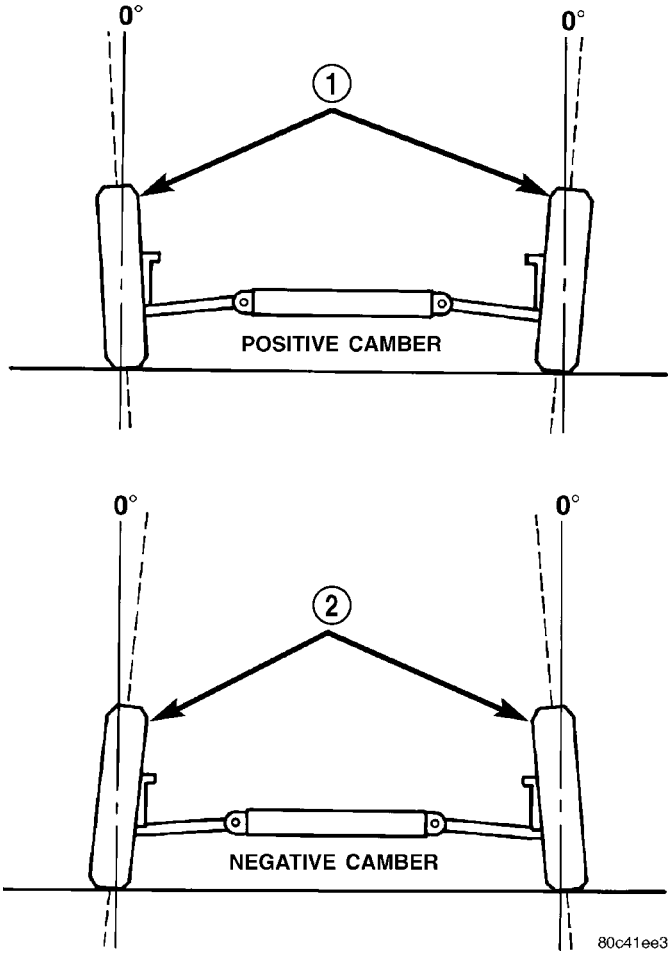

Fig. 1 Camber

1 - WHEELS TILTED OUT AT TOP
2 - WHEELS TILTED IN AT TOP

WHEEL ALIGNMENT (Continued)

CROSS CAMBER

Cross camber is the difference between left and right camber. To achieve the cross camber reading, subtract the right side camber reading from the left. For example, if the left camber is +0.3° and the right camber is 0.0°, the cross camber would be +0.3°.

CASTER

Caster is the forward or rearward tilt of the steering knuckle in reference to the position of the upper and lower ball joints. Caster is measured in degrees of angle relative to a true vertical center line. This line is viewed from the side of the tire and wheel assembly (Fig. 2).

- Forward tilt (upper ball joint ahead of lower) results in a negative caster angle.
- Rearward tilt (upper ball joint trailing lower) results in a positive caster angle.

Although caster does not affect tire wear, a caster imbalance between the two front wheels may cause the vehicle to lead to the side with the least positive caster.

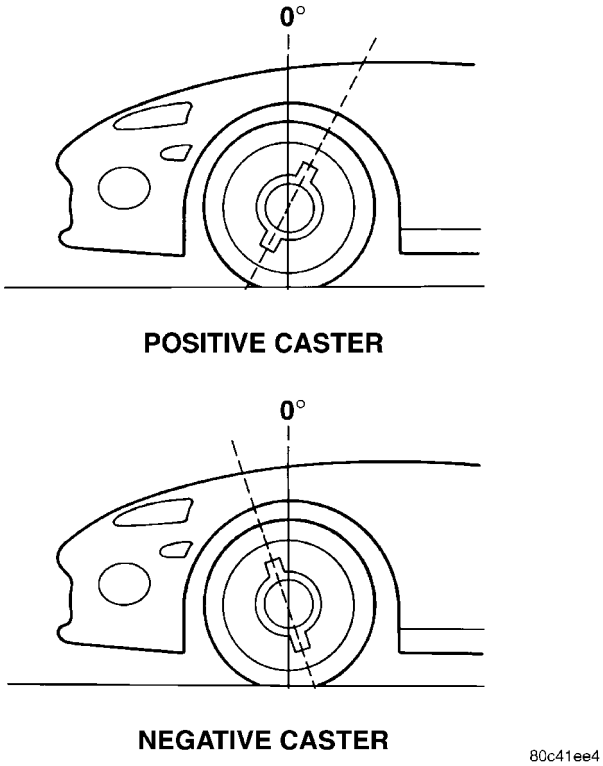

Fig. 2 Caster

CROSS CASTER

Cross caster is the difference between left and right caster.

TOE

Toe is the inward or outward angle of the wheels as viewed from above the vehicle (Fig. 3).

- Toe-in is produced when the front edges of the wheels on the same axle are closer together than the rear edges.
- Toe-out is produced when the front edges of the wheels on the same axle are farther apart than the rear edges.

Toe-in and toe-out can occur at the front wheels and the rear wheels.

Toe is measured in degrees or inches. The measurement identifies the amount that the front of the wheels point inward (toe-in) or outward (toe-out). Toe is measured at the spindle height. Zero toe means the front and rear edges of the wheels on the same axle are equally distant.

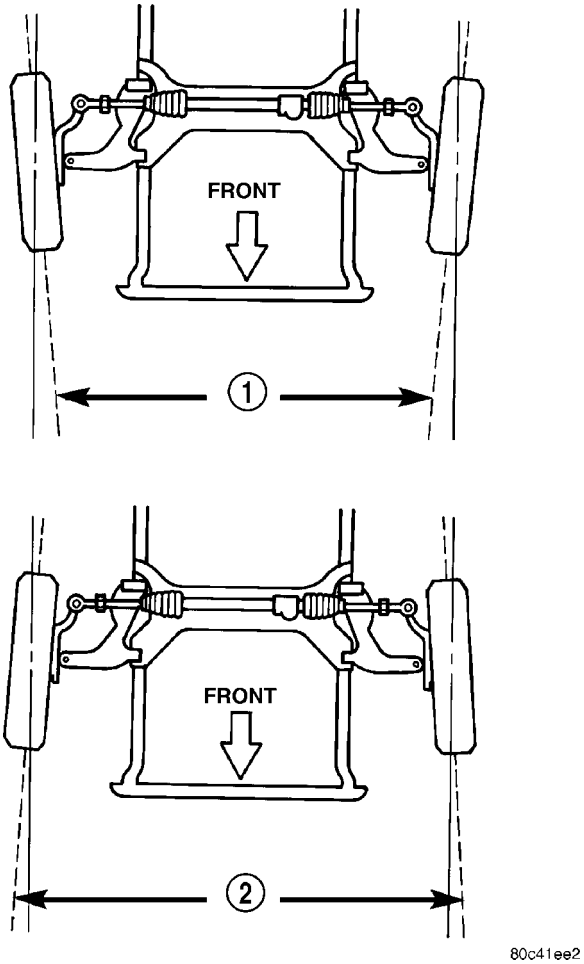

Fig. 3 Toe

1 - TOE-IN
2 - TOE-OUT

TOE-OUT ON TURNS

Toe-out on turns is the relative positioning of the front wheels while steering through a turn (Fig. 4). This compensates for each front wheel's turning radius. As the vehicle encounters a turn, the outboard wheel must travel in a larger radius circle than the inboard wheel. The steering system is

WHEEL ALIGNMENT (Continued)

designed to make each wheel follow its particular radius circle. To accomplish this, the front wheels must progressively toe outward as the steering is turned from center. This eliminates tire scrubbing and undue tire wear when steering a vehicle through a turn.

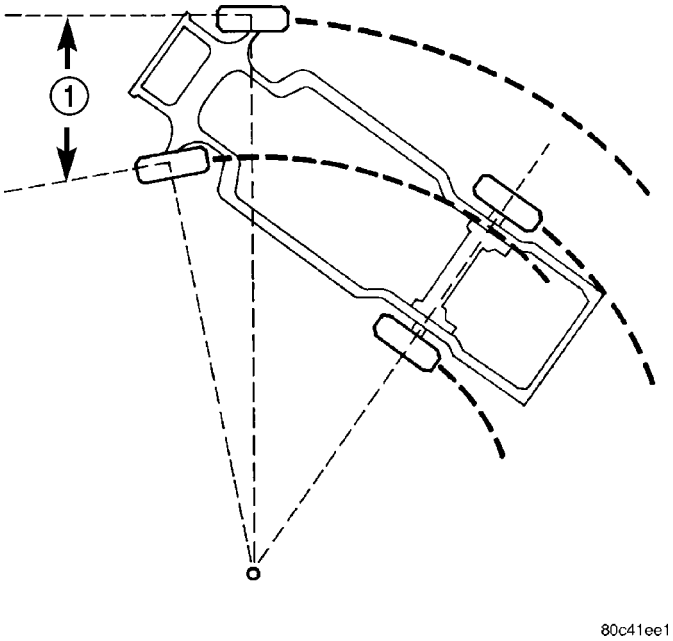

Fig. 4 Toe-Out On Turns

1 - TOE-OUT ON TURNS

DYNAMIC TOE PATTERN

Dynamic toe pattern is the inward and outward toe movement of the front and rear tires through the suspension's jounce and rebound travel. As the vehicle's suspension moves up and down, the toe pattern varies. Toe pattern is critical in controlling the directional stability of the vehicle while in motion. Front and rear dynamic toe pattern is preset by the factory at the time the vehicle is assembled.

It is not necessary to check or adjust front or rear dynamic toe pattern when doing a normal wheel alignment. The only time dynamic toe pattern needs to be checked or adjusted is if the frame of the vehicle has been damaged.

STEERING AXIS INCLINATION (S.A.I.)

Steering axis inclination is the angle between a true vertical line starting at the center of the tire at the road contact point and a line drawn through the center of the upper ball joint (or strut) and the lower ball joint (Fig. 5). S.A.I. is built into the vehicle and is not an adjustable angle. If S.A.I. is not within specifications, a bent or damaged suspension component may be the cause.

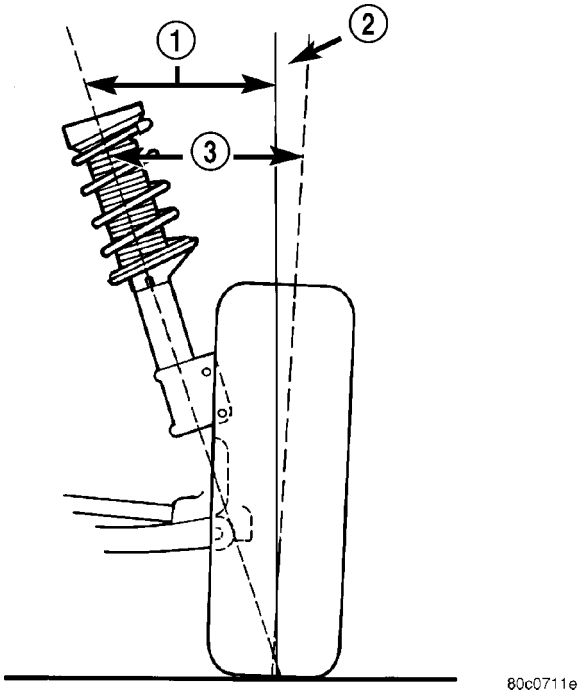

Fig. 5 S.A.I. and I.A.

1 - S.A.I.
2 - CAMBER
3 - I.A.

INCLUDED ANGLE (I.A.)

Included angle is the sum of the S.A.I. angle plus or minus the camber angle, depending on whether or not the wheel has positive or negative camber (Fig. 5). If camber is positive, add the camber angle to the S.A.I angle. If camber is negative, subtract the camber angle from the S.A.I. angle. Included angle is not adjustable, but can be used to diagnose a frame misalignment or bent suspension component (spindle, strut).

THRUST ANGLE

Thrust angle is the averaged direction the rear wheels are pointing in relation to the vehicle's center line (Fig. 6). The presence of negative or positive thrust angle causes the rear tires to track improperly to the left or right of the front tires (dog tracking).

- Negative thrust angle means the rear tires are tracking to the left of the front tires.
- Positive thrust angle means the rear tires are tracking to the right of the front tires.

Improper tracking can cause undue tire wear, a lead or pull and a crooked steering wheel. Excessive thrust angle can usually be corrected by adjusting the rear wheel toe so that each wheel has one-half of the total toe measurement.

WHEEL ALIGNMENT (Continued)

STANDARD PROCEDURE

STANDARD PROCEDURE - CURB HEIGHT MEASUREMENT

The wheel alignment is to be checked and all alignment adjustments made with the vehicle at its required curb height specification.

Vehicle height is to be checked with the vehicle on a flat, level surface, preferably a vehicle alignment rack. The tires are to be inflated to the recommended pressure. All tires are to be the same size as standard equipment. Vehicle height is checked with the fuel tank full of fuel, and no passenger or luggage compartment load.

Vehicle height is not adjustable. If the measurement is not within specifications, inspect the vehicle for bent or weak suspension components. Compare the parts tag on the suspect coil spring(s) to the parts book and the vehicle sales code, checking for a match. Once removed from the vehicle, compare the coil spring height to a correct new or known good coil spring. The heights should vary if the suspect spring is weak.

NOTE: Prior to reading the curb height measurement, the front an rear of the vehicle should be jounced. Induce jounce by grasping the center of the rear, then front bumper (or fascia) and jouncing the vehicle an equal number of times. Release the bumper at the bottom of the jounce cycle.

(1) Measure from the edge of the wheel opening fender lip directly above the wheel center (spindle) down to the floor or alignment rack surface.

(2) When measuring, maximum left-to-right differential is not to exceed 10 mm (0.39 in.).

(3) Compare the measurements to specifications listed in the following CURB HEIGHT SPECIFICATIONS chart.

WHEEL ALIGNMENT (Continued)

CURB HEIGHT SPECIFICATIONS

VEHICLE	FRONT	REAR
ALL	695 mm ± 8 mm 27.37 in. ± 0.32 in.	716 mm ± 8 mm 28.27 in. ± 0.32 in.

STANDARD PROCEDURE - WHEEL ALIGNMENT

PRE-WHEEL ALIGNMENT INSPECTION

CAUTION: If during the inspection the front suspension crossmember shows any sign of impact damage, the steering column lower coupling must be inspected. (Refer to 19 - STEERING/COLUMN/ STEERING COUPLING - DIAGNOSIS AND TESTING)

Before any attempt is made to change or correct the wheel alignment, the following inspection and necessary corrections must be made to the vehicle to ensure proper alignment.

(1) Be sure the fuel tank is full of fuel. If the fuel tank is not full, the reduction in weight will affect the curb height of the vehicle and the alignment specifications.

(2) The passenger and luggage compartments of the vehicle should be free of any load that is not factory equipment.

(3) Check the tires on the vehicle. The tires are to be inflated to the recommended air pressure. All tires must be the same size and in good condition with approximately the same tread wear.

(4) Check the front tire and wheel assemblies for excessive radial runout.

(5) Inspect all suspension component fasteners for looseness and proper torque.

(6) Inspect the lower front ball joints and all steering linkage for looseness and any sign of wear or damage.

(7) Inspect the rubber bushings on all the suspension components for signs of wear or deterioration. If any bushings show signs of wear or deterioration, they should be replaced prior to aligning the vehicle.

(8) Check vehicle curb height to verify it is within specifications. (Refer to 2 - SUSPENSION/WHEEL ALIGNMENT - STANDARD PROCEDURE)

WHEEL ALIGNMENT SETUP

(1) Position the vehicle on an alignment rack.

(2) Install all required alignment equipment on the vehicle, per the alignment equipment manufacturer's instructions. On this vehicle, a four-wheel alignment is recommended.

NOTE: Prior to reading the vehicle's alignment readouts, the front and rear of vehicle should be jounced. Induce jounce (rear first, then front) by grasping the center of the bumper and jouncing each end of vehicle an equal number of times. The bumper should always be released when vehicle is at the bottom of the jounce cycle.

(3) Read the vehicle's current front and rear alignment settings. Compare the vehicle's current alignment settings to the vehicle specifications for camber, caster and toe-in. (Refer to 2 - SUSPENSION/ WHEEL ALIGNMENT - SPECIFICATIONS)

REAR CAMBER AND TOE

Rear camber and rear toe settings on this vehicle are determined at the time the vehicle is designed, by the location of the vehicle's suspension components. This is referred to as Net Build. The result is no required adjustment of camber and toe after the vehicle is built or when servicing the suspension components. Thus, when performing a wheel alignment, rear camber and toe are not normally considered adjustable angles. Although not normally considered adjustable, rear camber and toe can be changed when necessary through the use of specially designed shims. To install shims, use the following procedure.

(1) Raise the vehicle until its tires are off the floor or alignment rack.

(2) Remove the tire and wheel assembly.

(3) Access the spindle mounting bolts following the Spindle Removal procedure found in Rear Suspension. (Refer to 2 - SUSPENSION/REAR/SPINDLE - REMOVAL)

(4) Loosen the four spindle mounting bolts just enough to slide the adjustment shim in between the spindle and the axle mounting flange.

NOTE: Each shim is 0.010 in. (0.254 mm) thick. Do not place more than two shims at any one spindle.

(5) Hook the shim on the mounting bolts utilizing the slots cut into the shim. Refer to the following list for shim placement:

- To achieve more positive camber, place the shim across the two upper mounting bolts.
- To achieve more negative camber, place the shim across the two lower mounting bolts.
- To achieve more positive toe, place the shim across the two rearward mounting bolts.
- To achieve more negative toe, place the shim across the two forward mounting bolts.

WHEEL ALIGNMENT (Continued)

(6) Tighten the four mounting bolts to a torque of 95 N·m (70 ft. lbs.).

(7) Reassemble the rear brake following the Spindle Installation procedure found in Rear Suspension. (Refer to 2 - SUSPENSION/REAR/SPINDLE - INSTALLATION)

(8) Reinstall the tire and wheel assembly. Tighten the wheel mounting nuts to a torque of 135 N·m (100 ft. lbs.).

(9) Lower the vehicle.

(10) Once rear camber and toe have been set to specifications, check and adjust the front wheel alignment as necessary. Refer to FRONT CAMBER AND CASTER and FRONT TOE within this wheel alignment service procedure.

FRONT CAMBER AND CASTER

Front camber and caster settings on this vehicle are determined at the time the vehicle is designed, by the location of the vehicle's suspension components. This is referred to as Net Build. The result is no required adjustment of camber and caster after the vehicle is built or when servicing the suspension components. Thus, when performing a wheel alignment, caster and camber are not normally considered adjustable angles. Camber and caster should be checked to ensure they meet vehicle specifications. (Refer to 2 - SUSPENSION/WHEEL ALIGNMENT - SPECIFICATIONS)

If front camber is found not to meet alignment specifications, it can be adjusted using an available camber adjustment bolt package. Before installing a camber adjustment bolt package on a vehicle found to be outside the specifications, inspect the suspension components for any signs of damage or bending.

No adjustment can be made to the caster setting on this vehicle. If the vehicle's caster is not within alignment specifications, check for damaged suspension components or body parts.

CAUTION: Do not attempt to adjust the vehicles wheel alignment by heating or bending any of the suspension components.

CAMBER ADJUSTMENT BOLT PACKAGE INSTALLATION

The camber adjustment bolt package contains new bolts and nuts for attaching the strut clevis bracket to the steering knuckle. The bolts contained in the package are slightly undersize allowing for movement between the strut clevis bracket and the steering knuckle. The movement allowed by the undersize bolts provide approximately two degrees of camber adjustment per side of the vehicle. To install and adjust the camber adjustment bolt package, follow the procedure below.

(1) Raise the vehicle until its tires are not supporting the weight of the vehicle.

CAUTION: The knuckle to strut assembly attaching bolt shanks are serrated and must not be turned during removal. Remove the nuts while holding the bolts stationary.

(2) Remove the original upper bolt attaching the strut clevis bracket to the knuckle (Fig. 7).

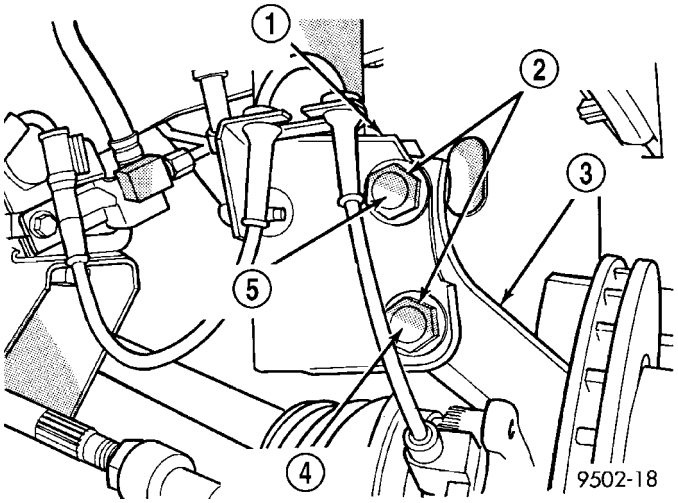

Fig. 7 Front Strut Clevis Bracket Attaching Bolts

1 - STRUT CLEVIS BRACKET
2 - STRUT CLEVIS BRACKET TO STEERING KNUCKLE ATTACHING BOLTS
3 - STEERING KNUCKLE
4 - LOOSEN THIS BOLT
5 - REMOVE AND REPLACE THIS BOLT

(3) Install a bolt from the adjustment package into the hole where the original bolt was removed. Install the bolt from the rear.

(4) Install a nut provided in adjustment package on the replacement bolt. Tighten the nut until it's snug, but still allowing the knuckle to slide in the clevis bracket.

(5) Remove the original lower bolt.

(6) Install a bolt from the adjustment package into the bottom hole of the strut clevis bracket. Install the bolt from the rear.

(7) Install a nut provided in adjustment package on the replacement bolt. Tighten the nut until it's snug.

(8) Reinstall the tire and wheel assembly. Tighten the wheel mounting nuts to a torque of 135 N·m (100 ft. lbs.)

(9) Perform the above procedure to opposite strut as required.

(10) Lower the vehicle and jounce the front and rear of the vehicle.

(11) Adjust the front camber to the preferred setting by pushing or pulling on the top of the tire. When camber is set to specifications, tighten the

WHEEL ALIGNMENT (Continued)

upper and lower strut clevis bracket bolts. Again jounce the front and rear of the vehicle, then verify the camber settings.

(12) Torque front strut clevis bracket-to-steering knuckle attaching bolts to a torque of 163 N·m (120 ft. lbs.).

(13) Once camber is within specifications, adjust toe to meet the preferred specification setting. Refer to FRONT TOE within this wheel alignment service procedure.

FRONT TOE

(1) Center the steering wheel and lock it in place using a steering wheel clamp.

CAUTION: Do not twist the inner tie rod-to-steering gear rubber boots while turning the inner tie rod during the front toe adjustment.

(2) Loosen the tie rod adjusting jam nuts (Fig. 8). Grasp each inner tie rod at its splines and rotate it one way or the other until the front wheel toe is set to the preferred specification. (Refer to 2 - SUSPENSION/WHEEL ALIGNMENT - SPECIFICATIONS)

(3) Tighten tie rod adjusting jam nuts to a torque of 75 N·m (55 ft. lbs.).

(4) Make sure the inner tie rod-to-steering gear rubber boots are not twisted. If twisted, loosen the boot clamp at the inner tie rod and move the boot as necessary.

(5) Remove steering wheel clamp.

(6) Remove the alignment equipment.

(7) Road test the vehicle to verify the steering wheel is straight and the vehicle does not pull or wander.

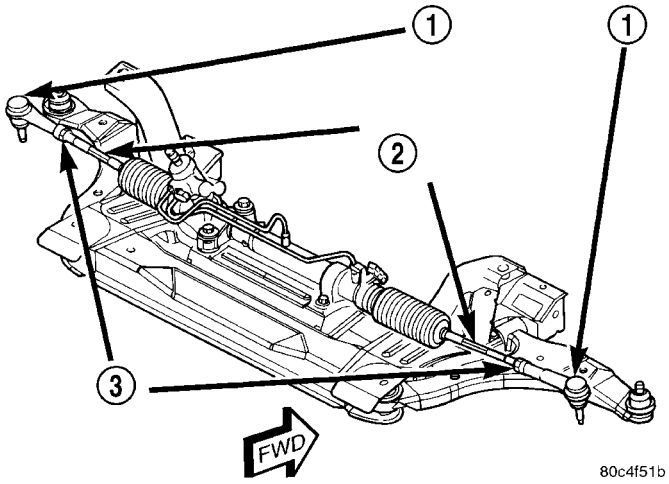

Fig. 8 Jam Nut Locations (Typical)

1 - OUTER TIE ROD
2 - INNER TIE ROD SPLINES
3 - JAM NUT

SPECIFICATIONS

WHEEL ALIGNMENT

NOTE: All specifications are given in degrees.

NOTE: All wheel alignments are to be set with the vehicle at curb height. (Refer to 2 - SUSPENSION/ WHEEL ALIGNMENT - STANDARD PROCEDURE)

FRONT WHEEL ALIGNMENT	PREFERRED SETTING	ACCEPTABLE RANGE
CAMBER	0.00°	-0.40° to +0.40°
Cross Camber (Maximum Side-To-Side Difference)	0.00°	0.50
CASTER	+2.45°	+1.45° to +3.45°
Cross Caster (Maximum Side-To-Side Difference)	0.00°	1.00°
TOTAL TOE*	+0.10°	0.00° to +0.20°
REAR WHEEL ALIGNMENT	**PREFERRED SETTING**	**ACCEPTABLE RANGE**
CAMBER	0.00°	-0.25° to +0.25°
TOTAL TOE*	+0.20°	+0.00° to +0.40°
THRUST ANGLE	0.00°	-0.30° to +0.30°

Note:

* TOTAL TOE is the sum of both the left and right wheel toe settings. TOTAL TOE must be equally split between each front wheel to ensure the steering wheel is centered after setting toe. Positive toe (+) is toe-in and negative toe (−) is Toe-out.

HALF SHAFT

DESCRIPTION

All Models Except Diesel and Turbo

1.6/2.4L naturally aspirated models equipped with either an automatic or manual transmission use an unequal-length halfshaft system. The system incorporates two halfshaft assemblies (left and right) that consist of an inner and outer constant velocity (CV) joint and a solid interconnecting shaft (Fig. 1). The right halfshaft is longer than the left due to transaxle packaging and powertrain design.

Halfshafts used on both the right and left sides of the vehicle use a tuned rubber damper weight mounted to the interconnecting shaft (Fig. 1). The damper weight applications vary by which side of the vehicle the halfshaft is located on and the transmission application of the vehicle. When replacing a halfshaft, be sure the replacement halfshaft has the same damper weight as the original.

Diesel and Turbo Models

Vehicles equipped with the 2.2L Turbo Diesel and the 2.4L Turbo Gasoline utilize an equal-length halfshaft system. The system incorporates two halfshaft assemblies (left and right) that consist of an inner and outer constant velocity (CV) joint and a solid interconnecting shaft, and an intermediate shaft/bearing assembly as shown in (Fig. 2)

The left halfshaft uses a tuned-rubber damper weight mounted to the interconnecting shaft (Fig. 2). When replacing a halfshaft, be sure the replacement halfshaft has the same damper weight as the original.

Both halfshaft assemblies use the same type of inner and outer joints. The inner joint of both halfshaft assemblies is a tripod joint, and the outer joint of both halfshaft assemblies is a Rzeppa joint. Both tripod joints and Rzeppa joints are true constant velocity (C/V) joint assemblies. The inner tripod joint allows for the changes in halfshaft length through the jounce and rebound travel of the front suspension.

On vehicles equipped with ABS brakes, the outer C/V joint is equipped with a tone wheel used to determine vehicle speed for ABS brake operation.

The left halfshaft inner tripod joint and the intermediate shaft are both splined into the transaxle side gears. The inner tripod joints are retained using a snap ring located in the stub shaft of the tripod joint. The outer C/V joint has a stub shaft that is splined into the wheel hub and retained by a hub nut and washer, nut lock, wave washer and cotter pin (Fig. 3).

NOTE: This vehicle does not use a rubber–lip bearing seal as on previous front–wheel–drive cars to prevent contamination of the front wheel bearing. On these vehicles, the face of the outer C/V joint fits deeply into the steering knuckle, using a close outer C/V joint–to–steering knuckle fit. This design deters direct water splash on bearing seal while allowing any water that gets in, to run out the bottom of the steering knuckle bearing bore. It is important to thoroughly clean the outer C/V joint and the wheel bearing area in the steering knuckle before it is assembled after servicing.

OPERATION

Halfshaft assemblies are designed to transmit power from the transaxle to the front wheels, while allowing for powertrain and suspension flex.

DIAGNOSIS AND TESTING - HALFSHAFT DIAGNOSIS

VEHICLE INSPECTION

(1) Check for grease in the vicinity of the inboard tripod joint and outboard C/V joint; this is a sign of inner or outer joint seal boot or seal boot clamp damage.

NOISE AND/OR VIBRATION IN TURNS

A clicking noise and/or a vibration in turns could be caused by one of the following conditions:

(1) Loose hub nut. Using a click-style torque wrench, torque hub nut to 244 N·m (180 ft. lbs.).

(2) Damaged outer C/V or inner tripod joint seal boot or seal boot clamps, which is evident by the presence of grease slung outward from the joint. This will result in the loss and/or contamination of the joint grease, resulting in inadequate lubrication of the joint.

HALF SHAFT (Continued)

(3) Noise may also be caused by another component of the vehicle coming in contact with the halfshafts.

CLUNKING NOISE DURING ACCELERATION

This noise may be a result of one of the following conditions:

(1) A torn seal boot on the inner or outer joint of the halfshaft assembly, which is evident by the presence of grease slung outward from the joint. This will result in the loss and/or contamination of the joint grease, resulting in inadequate lubrication of the joint.

(2) A loose or missing clamp on the inner or outer joint of the halfshaft assembly. This may be accompanied by the visible loss of grease.

(3) A damaged or worn halfshaft C/V joint. Isolate the noise to one side of the vehicle. Replace only the affected side. Replacing both halfshafts is not necessary.

SHUDDER OR VIBRATION DURING ACCELERATION

(1) A worn or damaged halfshaft inner tripod joint. Isolate the condition to one side of the vehicle. Replace only the affected side. Replacing both halfshafts is not necessary.

(2) A sticking tripod joint spider assembly (inner tripod joint only). Isolate the condition to one side of the vehicle. Replace only the affected side. Replacing both halfshafts is not necessary.

(3) Improper wheel balance.

VIBRATION AT HIGHWAY SPEEDS

(1) Foreign material (mud, etc.) packed on the backside of the wheel(s).

(2) Out of balance front tires or wheels.

(3) Improper tire and/or wheel runout.

REMOVAL

REMOVAL—EXCEPT DIESEL AND TURBO MODELS

CAUTION: Boot sealing is vital to retain special lubricants and to prevent foreign contaminants from entering the C/V joint. Mishandling, such as allowing the assemblies to dangle unsupported, or pulling or pushing the ends can cut boots or damage C/V joints. During removal and installation procedures, always support both ends of the halfshaft to prevent damage.

CAUTION: The halfshaft, when installed, acts as a bolt and secures the front hub/bearing assembly. If vehicle is to be supported or moved on its wheels with a halfshaft removed, install a PROPER–SIZED BOLT AND NUT through front hub. Tighten bolt and nut to 244 N·m (180 ft. lbs.). This will ensure that the hub bearing cannot loosen.

(1) Disconnect battery negative cable.

(2) Place transaxle in gated park.

(3) Raise vehicle on hoist.

(4) Remove wheel and tire assembly (Fig. 4).

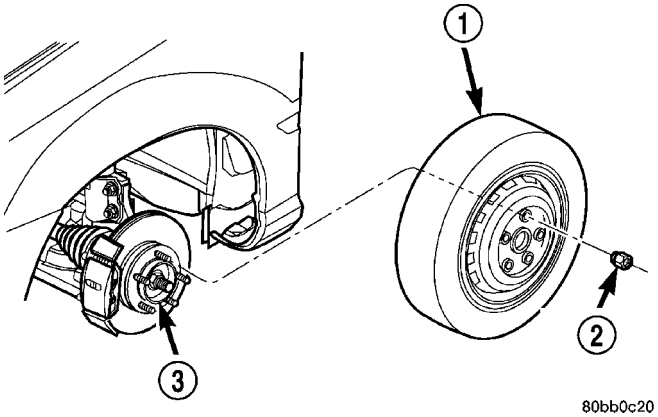

Fig. 4 Wheel and Tire Removal

1 - WHEEL/TIRE ASSY.
2 - LUG NUT (5)
3 - HUB

(5) Remove the cotter pin, nut lock, and spring washer, and hub nut from the end of the outer C/V joint stub axle (Fig. 5).

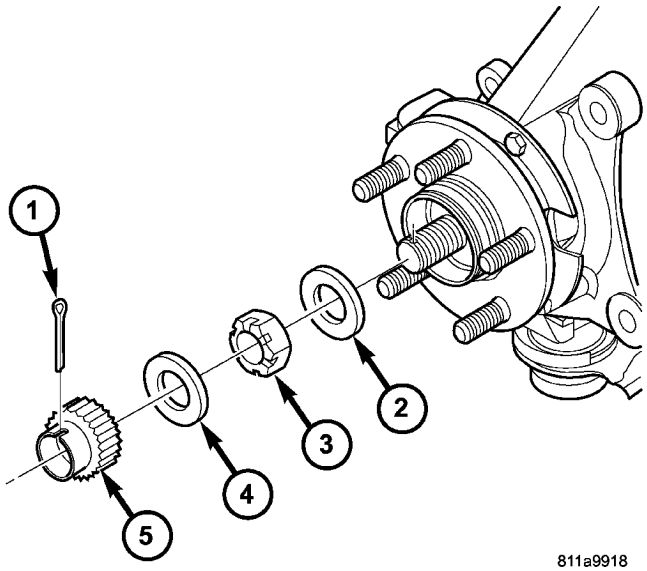

Fig. 5 Halfshaft Retaining Hardware

1 - COTTER KEY
2 - WASHER
3 - HUB NUT
4 - SPRING WASHER
5 - NUT LOCK

HALF SHAFT (Continued)

(6) If equipped with ABS, disconnect the front wheel speed sensor and secure harness out of the way.

(7) Remove nut and bolt (Fig. 6) retaining ball joint stud into steering knuckle.

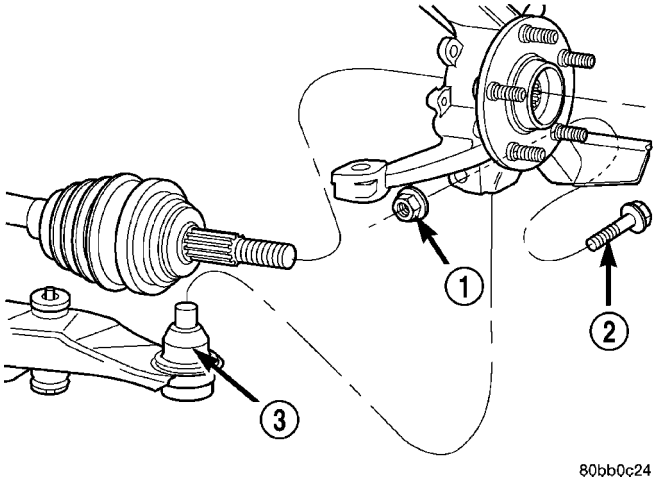

Fig. 6 Steering Knuckle at Lower Control Arm Ball Joint

1 - NUT
2 - BOLT
3 - BALL JOINT

NOTE: Use caution when separating ball joint stud from steering knuckle, so ball joint seal does not get damaged.

(8) Separate ball joint stud from steering knuckle by prying down on lower control arm (Fig. 7).

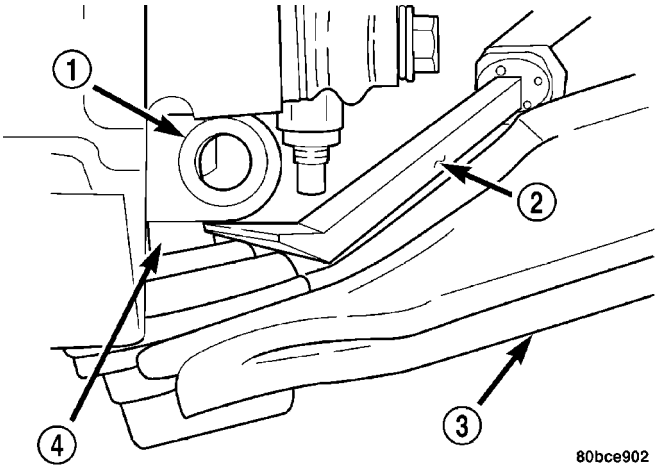

Fig. 7 Separating Lower Control Arm from Steering Knuckle

1 - STEERING KNUCKLE
2 - PRY BAR
3 - LOWER CONTROL ARM
4 - BALL JOINT STUD

NOTE: Care must be taken not to separate the inner C/V joint during this operation. Do not allow halfshaft to hang by inner C/V joint, halfshaft must be supported.

(9) Remove halfshaft from steering knuckle by pulling outward on knuckle while pressing in on halfshaft. Support outer end of halfshaft assembly. If difficulty in separating halfshaft from hub is encountered, **do not strike shaft with hammer,** instead use puller 1026 to separate (Fig. 8).

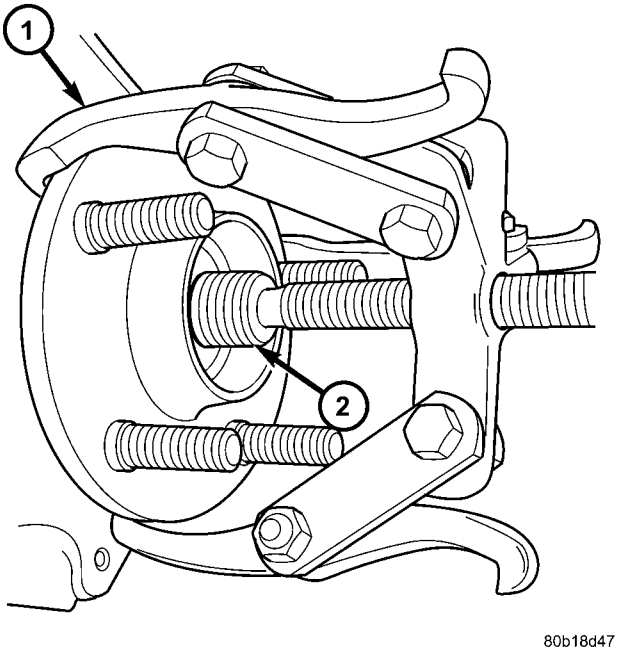

Fig. 8 Separating Halfshaft from Hub/Bearing

1 - PULLER 1026
2 - HALFSHAFT

(10) Remove halfshaft isolation washer (Fig. 9) and support outer end of the halfshaft assembly.

(11) Remove the inner tripod joints from the side gears of the transaxle using a punch to dislodge the inner tripod joint retaining ring from the transaxle side gear. If removing the right side inner tripod joint, position the punch to the inner tripod joint extraction groove (if equipped). Strike the punch sharply with a hammer to dislodge the right inner joint from the side gear. If removing the left side inner tripod joint, position the punch to the inner tripod joint extraction groove (Fig. 10). Strike the punch sharply with a hammer to dislodge the left inner tripod joint from the side gear.

NOTE: Removal of the inner tripod joints is made easier if you apply outward pressure on the joint as you strike the punch with a hammer. DO NOT PULL ON INTERCONNECTING SHAFT TO REMOVE, AS THE INNER JOINT WILL BECOME SEPARATED.

5 - NOTCH

(12) Hold inner tripod joint and interconnecting shaft of halfshaft assembly (Fig. 11). Remove inner tripod joint from transaxle by pulling it straight out of transaxle side gear and transaxle oil seal. **When removing tripod joint, do not let spline or snap ring drag across sealing lip of the transaxle to tripod joint oil seal. When tripod joint is removed from transaxle, some fluid will leak out.**

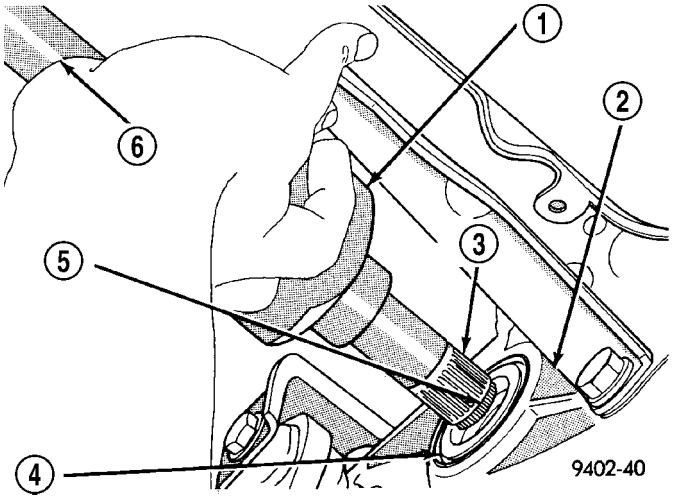

Fig. 11 Tripod Joint Removal from Transaxle

6 - INTERCONNECTING SHAFT

CAUTION: The halfshaft, when installed, acts as a bolt and secures the front hub/bearing assembly. If vehicle is to be supported or moved on its wheels with a halfshaft removed, install a PROPER–SIZED BOLT AND NUT through front hub. Tighten bolt and nut to 244 N·m (180 ft. lbs.). This will ensure that the hub bearing cannot loosen.

REMOVAL—DIESEL AND TURBO MODELS

CAUTION: Boot sealing is vital to retain special lubricants and to prevent foreign contaminants from entering the C/V joint. Mishandling, such as allowing the assemblies to dangle unsupported, or pulling or pushing the ends can cut boots or damage C/V joints. During removal and installation procedures, always support both ends of the halfshaft to prevent damage.

CAUTION: The halfshaft, when installed, acts as a bolt and secures the front hub/bearing assembly. If vehicle is to be supported or moved on its wheels with a halfshaft removed, install a PROPER–SIZED BOLT AND NUT through front hub. Tighten bolt and nut to 244 N·m (180 ft. lbs.). This will ensure that the hub bearing cannot loosen.

(1) Disconnect battery negative cable.
(2) Place transaxle in gated park.
(3) Raise vehicle on hoist.
(4) Remove wheel and tire assembly (Fig. 12).

(8) Separate ball joint stud from steering knuckle by prying down on lower control arm (Fig. 15).

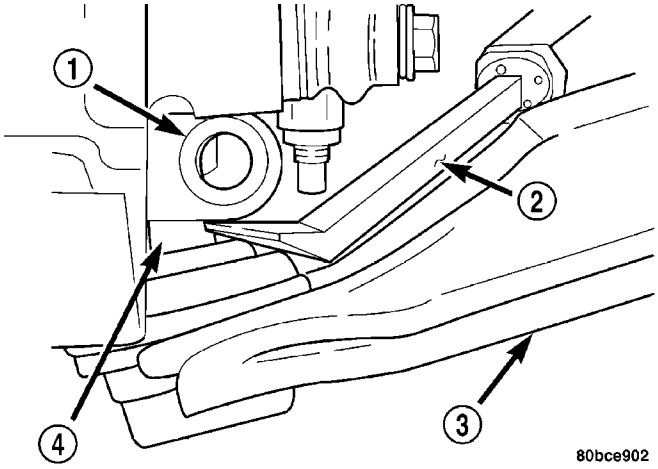

Fig. 15 Separating Lower Control Arm from Steering Knuckle

1 - STEERING KNUCKLE
2 - PRY BAR
3 - LOWER CONTROL ARM
4 - BALL JOINT STUD

NOTE: Care must be taken not to separate the inner C/V joint during this operation. Do not allow half-shaft to hang by inner C/V joint, halfshaft must be supported.

(9) Remove halfshaft from steering knuckle by pulling outward on knuckle while pressing in on half-shaft. Support outer end of halfshaft assembly. If difficulty in separating halfshaft from hub is encountered, **do not strike shaft with hammer,** instead use puller 1026 to separate (Fig. 16).

HALF SHAFT (Continued)

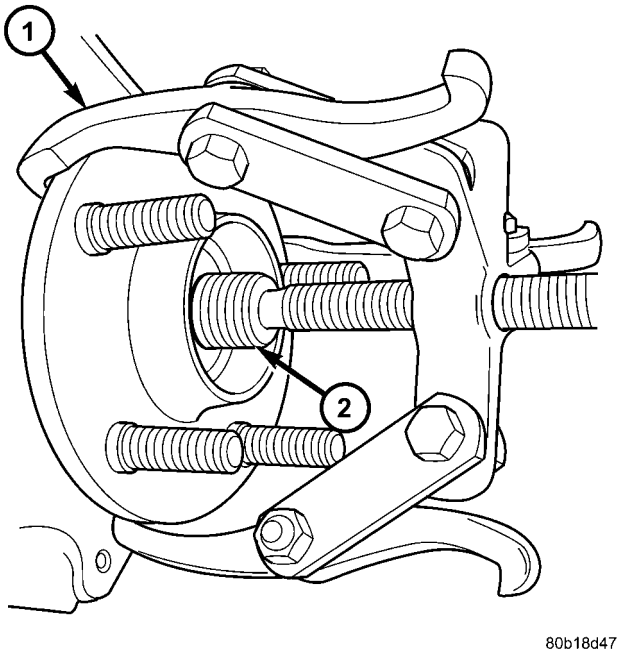

Fig. 16 Separating Halfshaft from Hub/Bearing

1 - PULLER 1026
2 - HALFSHAFT

(10) Remove halfshaft isolation washer (Fig. 17) and support outer end of the halfshaft assembly.

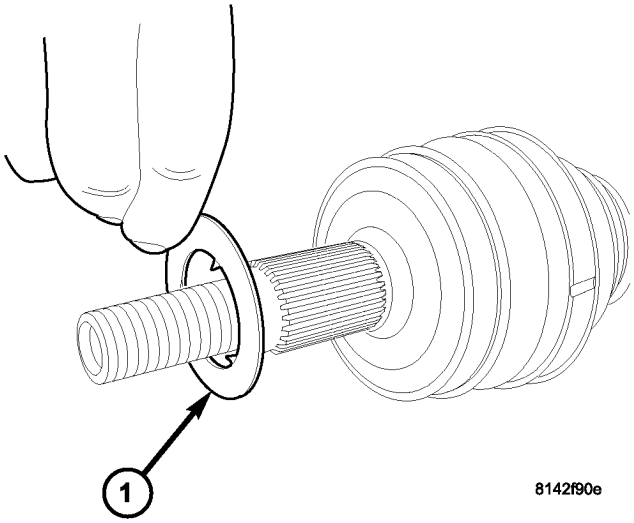

Fig. 17 Halfshaft Isolation Washer

1 - ISOLATION WASHER

NOTE: When left halfshaft is removed from transaxle, some fluid may leak out.

NOTE: Removal of the inner tripod joints is made easier if you apply outward pressure on the joint as you strike the punch with a hammer. DO NOT PULL ON INTERCONNECTING SHAFT TO REMOVE, AS THE INNER JOINT WILL BECOME SEPARATED.

(11) Remove halfshaft(s) (Fig. 18) (Fig. 19). **Left halfshaft:** While applying outward pressure on joint by hand, dislodge inner tripod joint from differential side gear by striking outward with a punch at extraction groove. When removing tripod joint and halfshaft, do not let spline or snap ring drag across sealing lip of the transaxle to tripod joint oil seal. **Right halfshaft:** Slide inner tripod joint off of intermediate shaft. If difficulty is encountered, dislodge joint from intermediate shaft using punch.

(12) If intermediate shaft is to be removed, remove three (3) intermediate shaft bearing-to-bracket bolts (Fig. 18). 2.4L turbo models utilize two (2) intermediate shaft bearing-to-bracket bolts. Remove intermediate shaft bearing/shaft assembly from transaxle.

CAUTION: The halfshaft, when installed, acts as a bolt and secures the front hub/bearing assembly. If vehicle is to be supported or moved on its wheels with a halfshaft removed, install a PROPER–SIZED BOLT AND NUT through front hub. Tighten bolt and nut to 244 N·m (180 ft. lbs.). This will ensure that the hub bearing cannot loosen.

INSTALLATION

INSTALLATION—EXCEPT DIESEL AND TURBO MODELS

CAUTION: Boot sealing is vital to retain special lubricants and to prevent foreign contaminants from entering the C/V joint. Mishandling, such as allowing the assemblies to dangle unsupported, or pulling or pushing the ends can cut boots or damage C/V joints. During removal and installation procedures, always support both ends of the halfshaft to prevent damage.

(1) Thoroughly clean spline and oil seal sealing surface, on tripod joint. Lightly lubricate oil seal sealing surface on tripod joint with fresh clean transmission lubricant.

(2) Holding halfshaft assembly by tripod joint and interconnecting shaft, install tripod joint into transaxle side gear as far as possible by hand.

(3) Carefully align tripod joint with transaxle side gears. Then grasp halfshaft interconnecting shaft and push tripod joint into transaxle side gear until fully seated. **Test that snap ring is fully engaged with side gear by attempting to remove tripod joint from transaxle by hand. If snap ring is fully engaged with side gear, tripod joint will not be removable by hand.**

(4) Clean all debris and moisture out of steering knuckle (Fig. 20).

(5) Ensure that front of outer C/V joint, which fits into steering knuckle (Fig. 21), is free of debris and moisture before assembling into steering knuckle.

(6) Install halfshaft isolation washer (Fig. 22) and slide halfshaft back into front hub.

(7) Install steering knuckle onto the ball joint stud (Fig. 23).

NOTE: At this point, the outer joint will not seat completely into the front hub. The outer joint will be pulled into hub and seated when the hub nut is installed and torqued.

HALF SHAFT (Continued)

INSTALLATION—DIESEL AND TURBO MODELS

CAUTION: Boot sealing is vital to retain special lubricants and to prevent foreign contaminants from entering the C/V joint. Mishandling, such as allowing the assemblies to dangle unsupported, or pulling or pushing the ends can cut boots or damage C/V joints. During removal and installation procedures, always support both ends of the halfshaft to prevent damage.

(1) If removed, install intermediate shaft/bearing assembly (Fig. 18) (Fig. 19). Install and torque bearing-to-bracket bolts to 28 N·m (21 ft. lbs.).

(2) Install halfshaft(s). **Left halfshaft:** Thoroughly clean spline and oil seal sealing surface on left tripod joint. Lightly lubricate oil seal sealing surface on tripod joint with fresh clean transmission lubricant. While holding halfshaft assembly by tripod joint and interconnecting shaft, install tripod joint into transaxle as far as possible by hand. Carefully align tripod joint with transaxle side gears. Then grasp halfshaft interconnecting shaft and push tripod joint into transaxle side gear until fully seated. Test that snap ring is fully engaged with side gear by attempting to remove tripod joint from transaxle by hand. If snap ring is fully engaged with side gear, tripod joint will not be removable by hand. **Right halfshaft:** Thoroughly clean right halfshaft tripod joint spline, as well as intermediate shaft spline. While holding halfshaft assembly by tripod joint and interconnecting shaft, install tripod joint onto intermediate shaft as far as possible by hand.

(3) Clean all debris and moisture out of steering knuckle (Fig. 26).

(4) Ensure that front of outer C/V joint, which fits into steering knuckle (Fig. 27), is free of debris and moisture before assembling into steering knuckle.

(5) Install halfshaft isolation washer and slide halfshaft back into front hub (Fig. 28).

(6) Install steering knuckle onto the ball joint stud (Fig. 29).

Boot Clamp Installer C-4975A

CV BOOT - INNER

REMOVAL

To remove sealing boot from halfshaft for replacement, the halfshaft assembly must be removed from the vehicle. (Refer to 3 - DIFFERENTIAL & DRIVELINE/HALF SHAFT - REMOVAL)

CAUTION: The inner tripod joints use no internal retention in the tripod housing to keep the spider assembly in the housing. Therefore, do not pull on the interconnecting shaft to disengage tripod housing from transmission stub shaft. Removal in this manner will cause damage to the inboard joint sealing boots.

(1) Remove the halfshaft requiring boot replacement from the vehicle. (Refer to 3 - DIFFERENTIAL & DRIVELINE/HALF SHAFT - REMOVAL)

(2) Remove large boot clamp that retains inner tripod joint sealing boot to tripod joint housing (Fig. 32) and discard. Then remove small clamp that retains inner tripod joint sealing boot to interconnecting shaft and discard. Remove the sealing boot from the tripod housing and slide it down the interconnecting shaft.

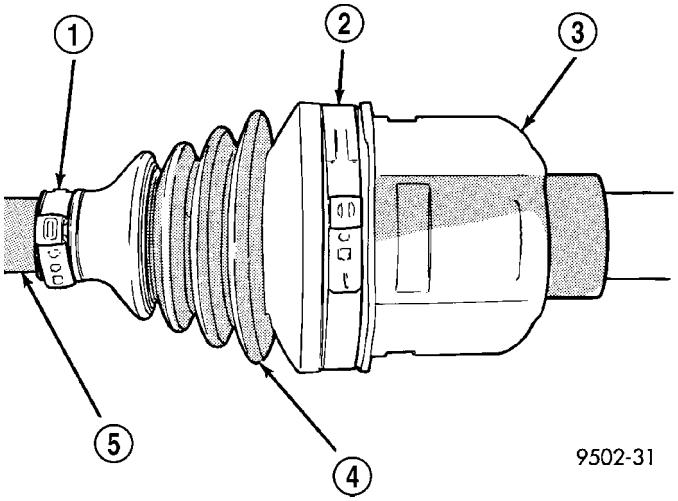

Fig. 32 Inner Tripod Joint Sealing Boot Clamps

1 - SMALL CLAMP
2 - LARGE CLAMP
3 - INNER TRIPOD JOINT
4 - SEALING BOOT
5 - INTERCONNECTING SHAFT

CAUTION: When removing the spider joint from the tripod joint housing, hold the rollers in place on the spider trunions to prevent the rollers and needle bearings from falling away.

(3) Slide the interconnecting shaft and spider assembly out of the tripod joint housing (Fig. 33).

CV BOOT - INNER (Continued)

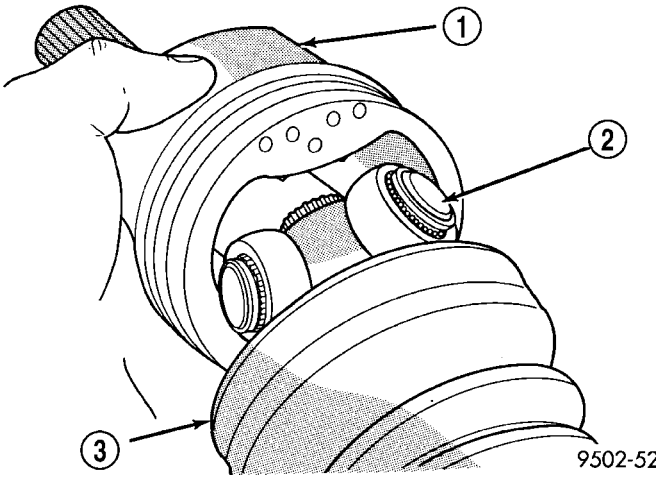

Fig. 33 Spider Assembly Joint Removal from Housing

1 - TRIPOD JOINT HOUSING
2 - SPIDER ASSEMBLY
3 - SEALING BOOT

(4) Remove snap ring that retains spider assembly to interconnecting shaft (Fig. 34). Remove the spider assembly from interconnecting shaft. If spider assembly will not come off interconnecting shaft by hand, it can be removed by tapping spider assembly with a brass drift (Fig. 35). **Do not hit the outer tripod bearings in an attempt to remove spider assembly from interconnecting shaft.**

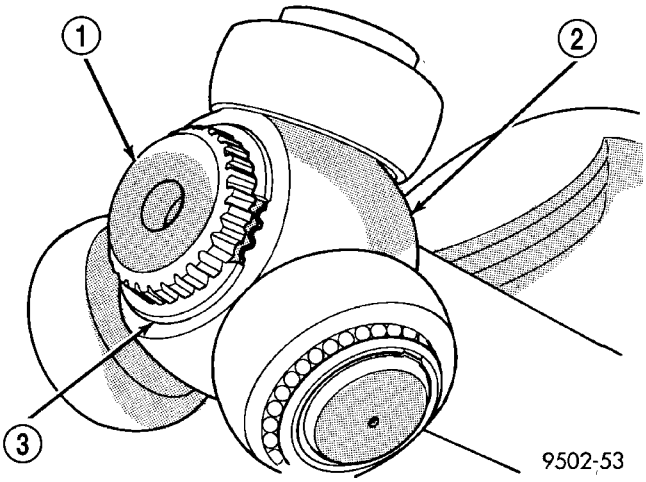

Fig. 34 Spider Assembly Retaining Snap Ring

1 - INTERCONNECTING SHAFT
2 - SPIDER ASSEMBLY
3 - RETAINING SNAP RING

(5) Slide sealing boot off interconnecting shaft.

(6) Thoroughly clean and inspect spider assembly, tripod joint housing, and interconnecting shaft for any signs of excessive wear. **If any parts show signs of excessive wear, the halfshaft assembly will require replacement. Component parts of these halfshaft assemblies are not serviceable.**

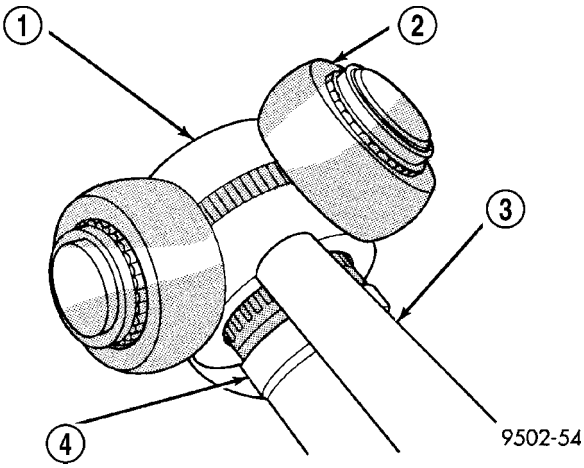

Fig. 35 Spider Assembly Removal from Interconnecting Shaft

1 - SPIDER ASSEMBLY
2 - DO NOT HIT SPIDER ASSEMBLY BEARINGS WHEN REMOVING SPIDER ASSEMBLY
3 - BRASS DRIFT
4 - INTERCONNECTING SHAFT

INSTALLATION

NOTE: The inner tripod joint sealing boots are made from two different types of material. High-temperature applications (close to exhaust system) use silicone rubber whereas standard temperature applications use Hytrel plastic. The silicone sealing boots are soft and pliable. The Hytrel sealing boots are stiff and rigid. The replacement sealing boot MUST BE the same type of material as the sealing boot that was removed.

(1) Slide inner tripod joint seal boot retaining clamp, onto interconnecting shaft. Then slide the replacement inner tripod joint sealing boot onto interconnecting shaft. **Inner tripod joint seal boot MUST be positioned on interconnecting shaft, so the raised bead on the inside of the seal boot is in groove on interconnecting shaft (Fig. 36).**

(2) Install spider assembly onto interconnecting shaft with chamfer on spider assembly toward interconnecting shaft (Fig. 37). Spider assembly must be installed on interconnecting shaft far enough to fully install spider retaining snap ring. If spider assembly will not fully install on interconnecting shaft by hand, it can be installed by tapping the spider body with a brass drift (Fig. 38). **Do not hit the outer tripod bearings in an attempt to install spider assembly on interconnecting shaft.**

2 - SPIDER ASSEMBLY
3 - RETAINING SNAP RING

CV BOOT - INNER (Continued)

(4) Distribute 1/2 the amount of grease provided in the seal boot service package (DO NOT USE ANY OTHER TYPE OF GREASE) into tripod housing. Put the remaining amount into the sealing boot.

(5) Align tripod housing with spider assembly and then slide tripod housing over spider assembly and interconnecting shaft (Fig. 40).

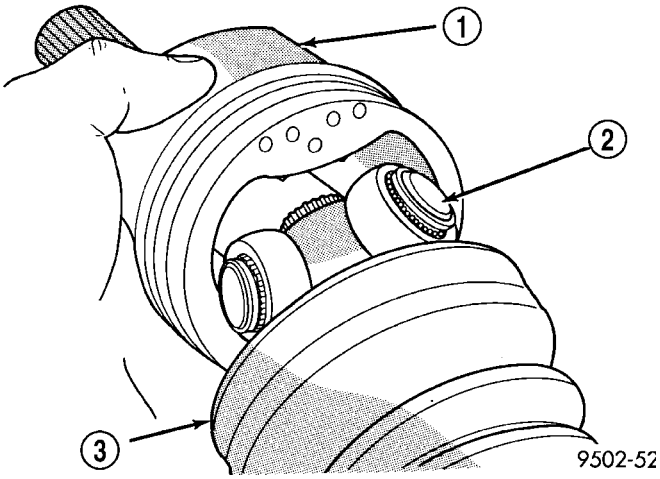

Fig. 40 Installing Tripod Housing on Spider Assembly

1 - TRIPOD JOINT HOUSING
2 - SPIDER ASSEMBLY
3 - SEALING BOOT

(6) Install inner tripod joint seal boot to interconnecting shaft clamp evenly on sealing boot.

(7) Clamp sealing boot onto interconnecting shaft using crimper, Special Tool C-4975-A and the following procedure. Place crimping tool C-4975-A over bridge of clamp (Fig. 41). Tighten nut on crimping tool C-4975-A until jaws on tool are closed completely together, face to face (Fig. 42).

CAUTION: Seal must not be dimpled, stretched, or out–of–shape in any way. If seal is NOT shaped correctly, equalize pressure in seal and shape it by hand.

(8) Position sealing boot into the tripod housing retaining groove. Install seal boot retaining clamp evenly on sealing boot.

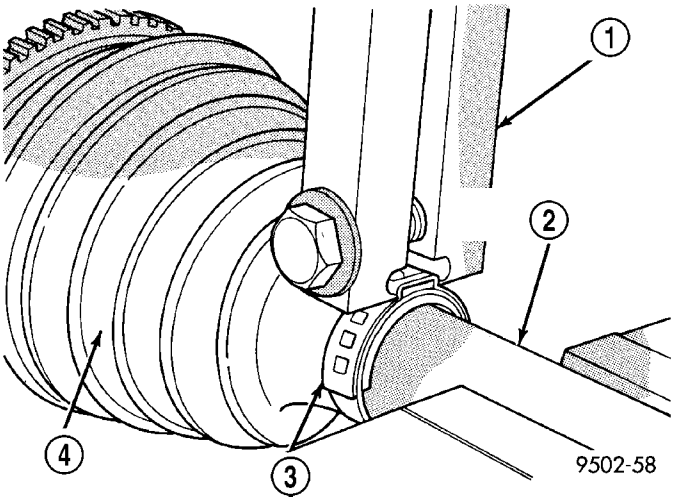

Fig. 41 Crimping Tool Installed on Sealing Boot Clamp

1 - SPECIAL TOOL C-4975A
2 - INTERCONNECTING SHAFT

CV BOOT - INNER (Continued)

CAUTION: The following positioning procedure determines the correct air pressure inside the inner tripod joint assembly prior to clamping the sealing boot to inner tripod joint housing. If this procedure is not done prior to clamping sealing boot to tripod joint housing, boot durability can be adversely affected.

CAUTION: When venting the inner tripod joint assembly, use care so inner tripod sealing boot does not get punctured or, in any other way, damaged. If sealing boot is punctured or damaged while being vented, the sealing boot can not be used.

(9) Insert a trim stick between the tripod joint and the sealing boot to vent inner tripod joint assembly (Fig. 43). **When inserting trim stick between tripod housing and sealing boot, ensure trim stick is held flat and firmly against the tripod housing. If this is not done, damage to the sealing boot can occur.** If inner tripod joint has a Hytrel (hard plastic) sealing boot, be sure trim stick is inserted between soft rubber insert and tripod housing, and not the hard plastic sealing boot and soft rubber insert.

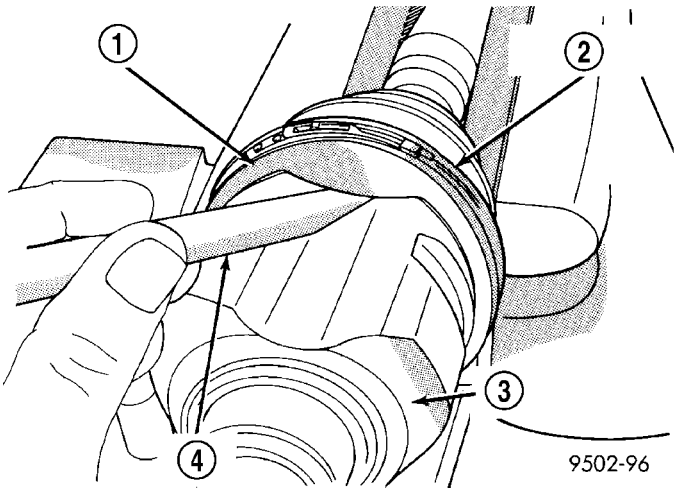

Fig. 43 Trim Stick Inserted for Venting Tripod Joint

1 - INNER TRIPOD JOINT SEALING BOOT
2 - SEALING BOOT CLAMP
3 - INNER TRIPOD JOINT HOUSING
4 - TRIM STICK

(10) With trim stick inserted between sealing boot and tripod joint housing, position inner tripod joint on halfshaft until correct sealing boot edge to edge length is obtained for type of sealing boot material being used (Fig. 44) (Fig. 45). Then remove the trim stick.

CV BOOT - INNER (Continued)

(11) Clamp tripod joint sealing boot to tripod joint using required procedure for type of boot clamp application. If seal boot uses crimp type boot clamp, clamp sealing boot onto tripod housing using crimper, Special Tool C-4975-A. Place crimping tool C-4975-A over bridge of clamp (Fig. 46). Tighten nut on crimping tool C-4975-A until jaws on tool are closed completely together, face–to–face (Fig. 47).

4 - JAWS OF SPECIAL TOOL C-4975A MUST BE CLOSED COMPLETELY TOGETHER HERE
5 - SEALING BOOT

(12) If seal boot uses low profile latching type boot clamp, clamp sealing boot onto tripod housing using clamp locking tool, Snap-On® YA3050 (or an equivalent). Place prongs of clamp locking tool in the holes of the clamp (Fig. 48). Squeeze tool together until top band of clamp is latched behind the two tabs on lower band of clamp (Fig. 49).

(13) Install the halfshaft requiring boot replacement back on the vehicle. (Refer to 3 - DIFFERENTIAL & DRIVELINE/HALF SHAFT - INSTALLATION)

CV BOOT - OUTER

REMOVAL

(1) Remove halfshaft assembly requiring boot replacement from vehicle. (Refer to 3 - DIFFERENTIAL & DRIVELINE/HALF SHAFT - REMOVAL)

(2) Remove large boot clamp retaining C/V joint sealing boot to C/V joint housing (Fig. 50) and discard. Remove small clamp that retains outer C/V joint sealing boot to interconnecting shaft and discard. Remove sealing boot from outer C/V joint housing and slide it down interconnecting shaft.

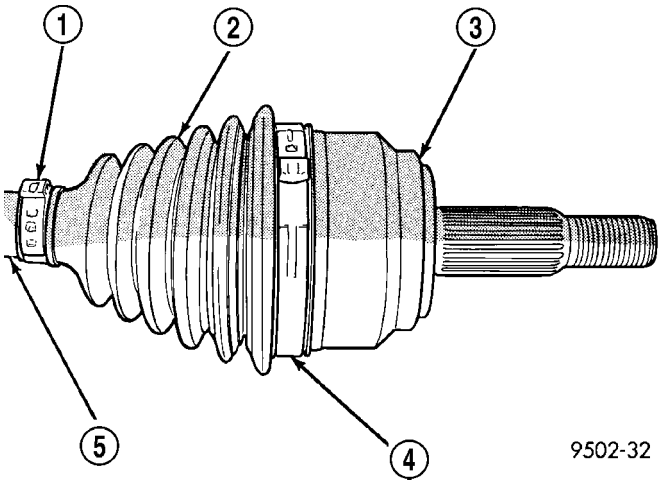

Fig. 50 Outer C/V Joint Seal Boot Clamps

1 - SMALL CLAMP
2 - SEALING BOOT
3 - OUTER C/V JOINT HOUSING
4 - LARGE CLAMP
5 - INTERCONNECTING SHAFT

(3) Wipe away grease to expose outer C/V joint and interconnecting shaft.

(4) Remove outer C/V joint from interconnecting shaft using the following procedure: Support interconnecting shaft in a vise equipped with protective caps on jaws of vise to prevent damage to interconnecting shaft. Then, using a soft–faced hammer, sharply hit the end of the C/V joint housing to dislodge housing from internal circlip on interconnecting shaft (Fig. 51). Then slide outer C/V joint off end of interconnecting shaft, joint may have to be tapped off shaft using a **soft–faced** hammer.

(5) Remove large circlip (Fig. 52) from the interconnecting shaft before attempting to remove outer C/V joint sealing boot.

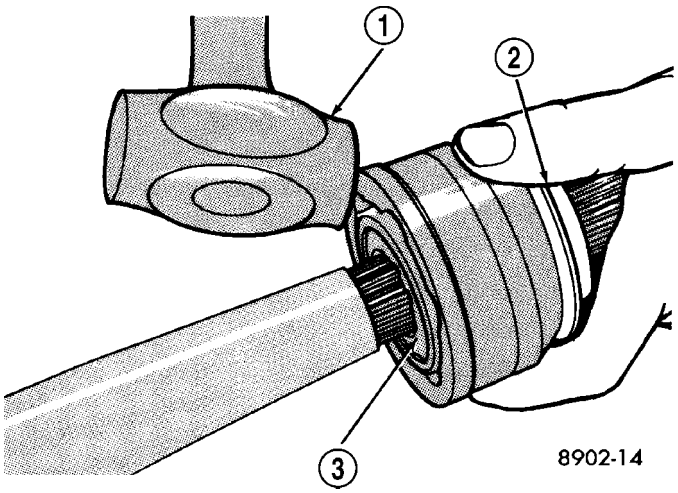

Fig. 51 Outer C/V Joint Removal from Interconnecting Shaft

2 - WEAR SLEEVE
3 - CIRCLIP (OUTER END OF SHAFT)

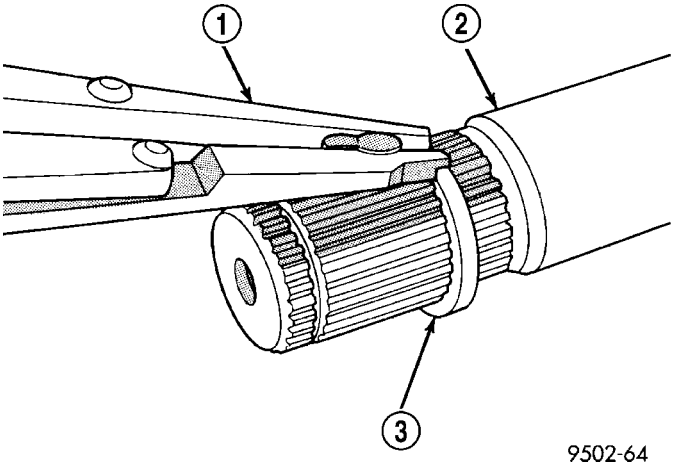

Fig. 52 Circlip Removal from Interconnecting Shaft

1 - SNAP RING PLIERS
2 - INTERCONNECTING SHAFT
3 - CIRCLIP

(6) Slide sealing boot off interconnecting shaft.

(7) Thoroughly clean and inspect outer C/V joint assembly and interconnecting joint for any signs of excessive wear. **If any parts show signs of excessive wear, the halfshaft assembly will require replacement. Component parts of these halfshaft assemblies are not serviceable.**

CV BOOT - OUTER (Continued)

INSTALLATION

(1) Slide new sealing boot to interconnecting shaft retaining clamp onto interconnecting shaft. Slide the outer C/V joint assembly sealing boot onto the interconnecting shaft (Fig. 53). **Seal boot MUST be positioned on interconnecting shaft so the raised bead on the inside of the seal boot is in groove on interconnecting shaft.**

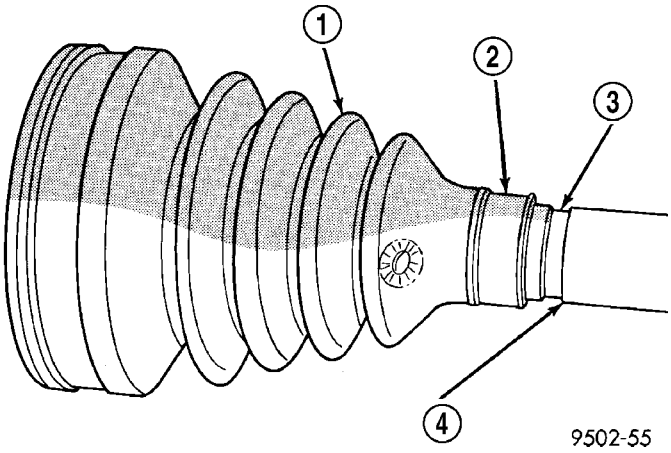

Fig. 53 Sealing Boot Installation on Interconnecting Shaft

1 - SEALING BOOT
2 - RAISED BEAD IN THIS AREA OF SEALING BOOT
3 - GROOVE
4 - INTERCONNECTING SHAFT

(2) Align splines on interconnecting shaft with splines on cross of outer C/V joint assembly and start outer C/V joint onto interconnecting shaft.

(3) Install outer C/V joint assembly onto interconnecting shaft by using a **soft–faced** hammer and tapping end of stub axle (with hub nut installed) until outer C/V joint is fully seated on interconnecting shaft (Fig. 54).

(4) Outer C/V joint assembly must be installed on interconnecting shaft until cross of outer C/V joint assembly is seated against circlip on interconnecting shaft (Fig. 55).

(5) Distribute 1/2 the amount of grease provided in seal boot service package (DO NOT USE ANY OTHER TYPE OF GREASE) into outer C/V joint assembly housing. Put the remaining amount into the sealing boot.

(6) Install outer C/V joint sealing boot to interconnecting shaft clamp evenly on sealing boot.

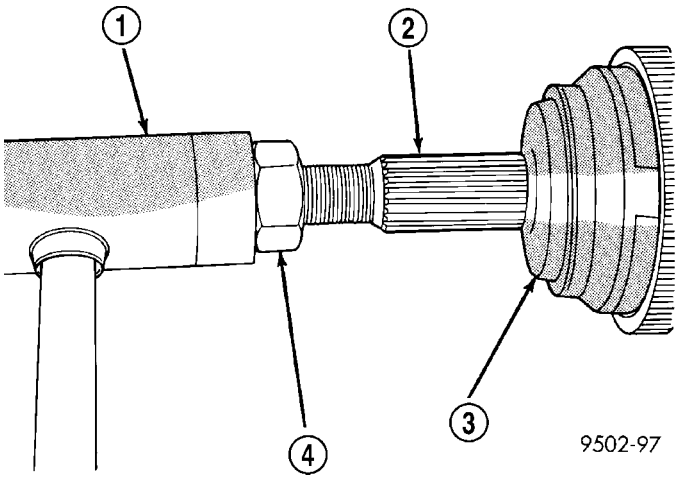

Fig. 54 Outer C/V Joint Installation on Interconnecting

BRAKES - BASE

DESCRIPTION - BASE BRAKE SYSTEM

The base brake system consists of the following components:

- Brake pedal
- Brake lamp switch
- Power brake booster
- Master cylinder
- Proportioning valves (2) (non-ABS vehicles only)
- Brake tubes and hoses
- Disc brakes (front)
- Disc brakes (rear) (optional)
- Drum brakes (rear)
- Parking brake

The hydraulic brake system is diagonally split on both the non-antilock and antilock braking systems. This means the left front and right rear brakes are on one hydraulic circuit and the right front and left rear are on the other.

Front disc brakes control the braking of the front wheels; rear braking is controlled by rear drum brakes as standard equipment. Rear disc brakes and antilock brakes with or without traction control are optional.

Vehicles equipped with the optional antilock brake system (ABS) use a system that shares most base brake hardware used on vehicles without ABS. For more information on ABS (Refer to 5 - BRAKES - ABS - DESCRIPTION).

The parking brake system consists of a hand-operated lever mounted between the front seats, two parking brake cables and parking brake shoes at each rear wheel. Only vehicles with rear disc brakes receive separate parking brake shoes. Vehicles with rear drum brakes utilize the service brakes as the parking brake shoes.

OPERATION - BASE BRAKE SYSTEM

When a vehicle needs to be stopped, the driver applies the brake pedal. The brake pedal pushes the input rod of the power brake booster into the booster. The booster uses vacuum to ease pedal effort as force is transferred through the booster to the master cylinder. The booster's output rod pushes in the master cylinder's primary and secondary pistons applying hydraulic pressure through the proportioning valves (non-ABS - rear only) and chassis brake tubes to the brakes at each tire and wheel assembly.

The parking brakes are hand-operated. When applied, the parking brake lever pulls on cables that actuate brake shoes at each rear wheel. The parking brake lever has an automatic-adjusting feature that takes up any excessive slack in the parking brake cable system.

WARNING

WARNING: DUST AND DIRT ACCUMULATING ON BRAKE PARTS DURING NORMAL USE MAY CONTAIN ASBESTOS FIBERS FROM PRODUCTION OR AFTERMARKET BRAKE LININGS. BREATHING EXCESSIVE CONCENTRATIONS OF ASBESTOS FIBERS CAN CAUSE SERIOUS BODILY HARM. EXERCISE CARE WHEN SERVICING BRAKE PARTS. DO NOT SAND OR GRIND BRAKE LINING UNLESS EQUIPMENT USED IS DESIGNED TO CONTAIN THE DUST RESIDUE. DO NOT CLEAN BRAKE PARTS WITH COMPRESSED AIR OR BY DRY BRUSHING. CLEANING SHOULD BE DONE BY DAMPENING THE BRAKE COMPONENTS WITH A FINE MIST OF WATER, THEN WIPING THE BRAKE COMPONENTS CLEAN WITH A DAMPENED CLOTH. DISPOSE OF CLOTH AND ALL RESIDUE CONTAINING ASBESTOS FIBERS IN AN IMPERMEABLE CONTAINER WITH THE APPROPRIATE LABEL. FOLLOW PRACTICES PRESCRIBED BY THE OCCUPATIONAL SAFETY AND HEALTH ADMINISTRATION (OSHA) AND THE ENVIRONMENTAL PROTECTION AGENCY (EPA) FOR THE HANDLING, PROCESSING, AND DISPOSING OF DUST OR DEBRIS THAT MAY CONTAIN ASBESTOS FIBERS.

CAUTION

CAUTION: Use only Mopar® Brake Fluid DOT 3 Motor Vehicle or equivalent from a tightly sealed container. Do not use petroleum-based fluid because seal damage in the brake system will result. (Refer to 5 - BRAKES/HYDRAULIC/MECHANICAL/FLUID - SPECIFICATIONS)

CAUTION: Brake fluid will damage painted surfaces. If brake fluid is spilled on any painted surfaces, wash it off immediately with water.

CAUTION: Never use gasoline, kerosene, alcohol, motor oil, transmission fluid, or any fluid containing mineral oil to clean system components. These fluids damage rubber cups and seals.

CAUTION: During service procedures, grease or any other foreign material must be kept off the caliper assembly, brake linings, brake rotor and external surfaces of the hub.

BRAKES - BASE (Continued)

CAUTION: When handling the brake rotor and caliper, be careful to avoid damaging the brake rotor and caliper, and scratching or nicking the brake shoe lining.

DIAGNOSIS AND TESTING - BASE BRAKE SYSTEM DIAGNOSIS CHARTS

NOTE: There are three diagnosis charts following that cover the RED BRAKE WARNING INDICATOR, BRAKE NOISE and OTHER BRAKE CONDITIONS.

RED BRAKE WARNING INDICATOR

CONDITION	POSSIBLE CAUSES	CORRECTION
RED BRAKE WARNING INDICATOR ON	1. Parking brake lever not fully released.	1. Release parking brake lever.
	2. Parking brake warning switch on parking brake lever.	2. Inspect and replace switch as necessary.
	3. Brake fluid level low in reservoir.	3. Fill reservoir. Check entire system for leaks. Repair or replace as required.
	4. Brake fluid level switch.	4. Disconnect switch wiring connector. If lamp goes out, replace switch.
	5. Mechanical instrument cluster (MIC) problem.	5. Refer to Appropriate Diagnostic Information.
	6. ABS EVBP malfunction.	6. Refer to ABS section and Appropriate Diagnostic Information.

BRAKE NOISE

CONDITION	POSSIBLE CAUSES	CORRECTION
DISC BRAKE CHIRP	1. Excessive brake rotor runout.	1. Refer to brake rotor - diagnosis and testing. Correct as necessary.
DISC BRAKE RATTLE OR CLUNK	1. Broken or missing spring clips.	1. Replace brake shoes.
	2. Caliper guide pin bolts loose.	2. Tighten guide pin bolts.
	3. Missing abutment shims.	3. Replace missing abutment shims.
DISC BRAKE SQUEAK AT LOW SPEED (WHILE APPLYING LIGHT BRAKE PEDAL EFFORT)	1. Brake shoe linings.	1. Replace brake shoes.
DRUM BRAKE CHIRP	1. Lack of lubricant on brake shoe support plate where shoes ride.	1. Lubricate shoe contact areas on brake shoe support plates.
	2. Wheel cylinder out of alignment.	2. Loosen wheel cylinder mounting bolts, realign wheel cylinder with brake shoes and tighten mounting bolts.
DRUM BRAKE CLUNK	1. Drum(s) have threaded machined braking surface.	1. Reface or replace drake drums as necessary.

BRAKES - BASE (Continued)

CONDITION	POSSIBLE CAUSES	CORRECTION
DRUM BRAKE HOWL OR MOAN	1. Lack of lubricant on brake shoe support plate where shoes ride and at the anchor.	1. Lubricate shoe contact areas on brake shoe support plates and at the anchor.
	2. Rear brake shoes.	2. Replace rear brake shoes.
SCRAPING (METAL-TO-METAL).	1. Foreign object interference with brakes.	1. Inspect brakes and remove foreign object.
	2. Brake shoes worn out.	2. Replace brake shoes. Inspect rotors and drums. Reface or replace as necessary.
SCRAPING OR WHIRRING	1. ABS wheel speed sensor hitting tone wheel.	1. Inspect, correct or replace faulty component(s).

OTHER BRAKE CONDITIONS

CONDITION	POSSIBLE CAUSES	CORRECTION
BRAKES CHATTER	1. Rear brake drum out of round or disc brake rotor has excessive thickness variation.	1. Isolate condition as rear or front. Reface or replace brake drums or rotors as necessary.
BRAKES DRAG (FRONT OR ALL)	1. Contaminated brake fluid.	1. Check for swollen seals. Replace all system components containing rubber.
	2. Binding caliper pins or bushings.	2. Replace pins and bushings
	3. Misadjusted brake lamp switch.	3. Replace brake lamp switch. (Refer to 8 - ELECTRICAL/LAMPS/LIGHTING - EXTERIOR/BRAKE LAMP SWITCH - REMOVAL)
	4. Master cylinder not fully returning.	4. Inspect master cylinder and replace as necessary.
	5. Binding brake pedal.	5. Replace brake pedal/bushings.
BRAKES DRAG (REAR ONLY)	1. Parking brake cables binding or froze up.	1. Check cable routing. Replace cables as necessary.
	2. Parking brake cable return spring not returning shoes.	2. Replace cables as necessary.
	3. Service brakes not adjusted properly (rear drum brakes only).	3. Adjust rear brake shoes. Refer to Brake Pads/Shoes - Drum Brake.
	4. Obstruction inside the center console preventing full return of the parking brake cables.	4. Remove console and remove obstruction.
BRAKES GRAB	1. Contaminated brake shoe linings.	1. Inspect and clean, or replace shoes. Repair source of contamination.
	2. Improper power brake booster assist.	2. Refer to Power Brake Booster in this section.

BRAKES - BASE (Continued)

CONDITION	POSSIBLE CAUSES	CORRECTION
EXCESSIVE PEDAL EFFORT	1. Obstruction of brake pedal.	1. Inspect, remove or move obstruction.
	2. Low power brake booster assist.	2. Refer to Power Brake Booster in this section.
	3. Glazed brake linings.	3. Reface or replace brake rotors as necessary. Replace brake shoes.
	4. Brake shoe lining transfer to brake rotor.	4. Reface or replace brake rotors as necessary. Replace brake shoes.
EXCESSIVE PEDAL EFFORT (HARD PEDAL - CAN'T SKID WHEELS)	1. Power brake booster runout (vacuum assist).	1. Check booster vacuum hose and engine tune for adequate vacuum supply. Refer to Power Brake Booster.
EXCESSIVE PEDAL TRAVEL (VEHICLE STOPS OK)	1. Air in brake lines.	1. Bleed brakes.
	2. Rear drum brake auto-adjuster malfunctioning.	2. Inspect and replace drum brake components as necessary. Adjust rear brakes.
EXCESSIVE PEDAL TRAVEL (ONE FRONT WHEEL LOCKS UP DURING HARD BRAKING)	1. One of the two hydraulic circuits is malfunctioning.	1. Inspect system for leaks. Check master cylinder for internal malfunction.
PEDAL PULSATES/ SURGES DURING BRAKING	1. Rear brake drum out of round or disc brake rotor has excessive thickness variation.	1. Isolate condition as rear or front. Reface or replace brake drums or rotors as necessary.
PEDAL IS SPONGY	1. Air in brake lines.	1. Bleed brakes.
PREMATURE REAR WHEEL LOCKUP	1. Contaminated brake shoe linings.	1. Inspect and clean, or replace shoes. Repair source of contamination.
	2. Inoperative proportioning valve (non-ABS vehicles only).	2. Test proportioning valves following diagnosis and testing procedure. Refer to Proportioning Valve. Replace valves as necessary.
	3. ABS EVBP not functioning.	3. Refer to the ABS section and Appropriate Diagnostic Information.
STOP LAMPS STAY ON	1. Brake lamp switch out of adjustment.	1. Replace brake lamp switch. (Refer to 8 - ELECTRICAL/LAMPS/LIGHTING - EXTERIOR/BRAKE LAMP SWITCH - REMOVAL)
	2. Brake pedal binding.	2. Inspect and replace as necessary.
	3. Power brake booster not allowing pedal to return completely.	3. Replace power brake booster.

BRAKES - BASE (Continued)

CONDITION	POSSIBLE CAUSES	CORRECTION
VEHICLE PULLS TO RIGHT OR LEFT ON BRAKING	1. Frozen brake caliper piston.	1. Replace frozen piston or caliper. Bleed brakes.
	2. Contaminated brake shoe lining (most likely front lining).	2. Inspect and clean, or replace shoes. Repair source of contamination.
	3. Pinched brake lines.	3. Replace pinched line.
	4. Leaking piston seal.	4. Replace piston seal or brake caliper.
	5. Suspension problem.	5. Refer to the Suspension section.
PARKING BRAKE - EXCESSIVE HANDLE TRAVEL	1. Rear brakes out of adjustment.	1. Adjust rear drum brake shoes, or rear parking brake shoes on vehicles with rear disc brakes.

STANDARD PROCEDURE - BASE BRAKE BLEEDING

NOTE: For bleeding the ABS hydraulic system, refer to Antilock Brake System Bleeding in the Antilock Brake System section.

CAUTION: Before removing the master cylinder cap, wipe it clean to prevent dirt and other foreign matter from dropping into the master cylinder reservoir.

CAUTION: Use only Mopar® brake fluid or an equivalent from a fresh, tightly sealed container. Brake fluid must conform to DOT 3 specifications.

Do not pump the brake pedal at any time while having a bleeder screw open during the bleeding process. This will only increase the amount of air in the system and make additional bleeding necessary.

Do not allow the master cylinder reservoir to run out of brake fluid while bleeding the system. An empty reservoir will allow additional air into the brake system. Check the fluid level frequently and add fluid as needed.

The following wheel circuit sequence for bleeding the brake hydraulic system should be used to ensure adequate removal of all trapped air from the hydraulic system.

- Left rear wheel
- Right front wheel
- Right rear wheel
- Left front wheel

MANUAL BLEEDING

NOTE: To bleed the brakes manually, the aid of a helper will be required.

(1) Attach a clear plastic hose to the bleeder screw and feed the hose into a clear jar containing enough fresh brake fluid to submerge the end of the hose (Fig. 1).

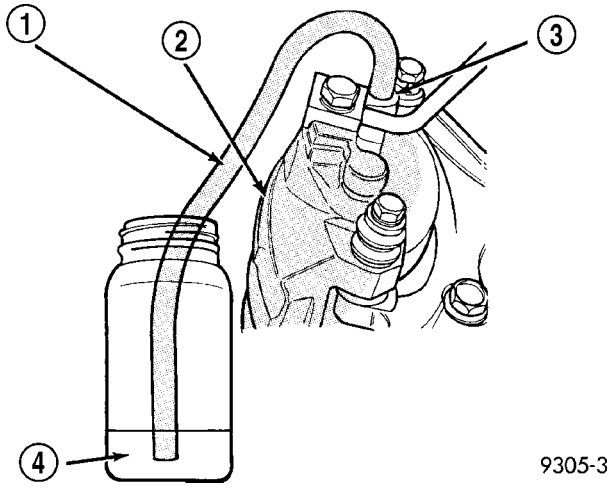

Fig. 1 Proper Method for Purging Air From Brake System (Typical)

1 - CLEAR HOSE
2 - BRAKE CALIPER
3 - BLEEDER SCREW
4 - CLEAN BRAKE FLUID

(2) Have a helper pump the brake pedal three or four times and hold it in the down position.

(3) With the pedal in the down position, open the bleeder screw at least 1 full turn.

(4) Once the brake pedal has dropped, close the bleeder screw. After the bleeder screw is closed, release the brake pedal.

(5) Repeat the above steps until all trapped air is removed from that wheel circuit (usually four or five times).

BRAKES - BASE (Continued)

(6) Bleed the remaining wheel circuits in the same manner until all air is removed from the brake system. Monitor the fluid level in the master cylinder reservoir to make sure it does not go dry.

(7) Check the brake pedal travel. If pedal travel is excessive or has not been improved, some air may still be trapped in the system. Rebleed the brakes as necessary.

(8) Test drive the vehicle to verify the brakes are operating properly and pedal feel is correct.

PRESSURE BLEEDING

NOTE: Follow pressure bleeder manufacturer's instructions for use of pressure bleeding equipment.

Following the same wheel circuit sequence as prescribed for manual bleeding.

(1) Attach Adapter, Special Tool 6921, to the master cylinder reservoir (Fig. 2).

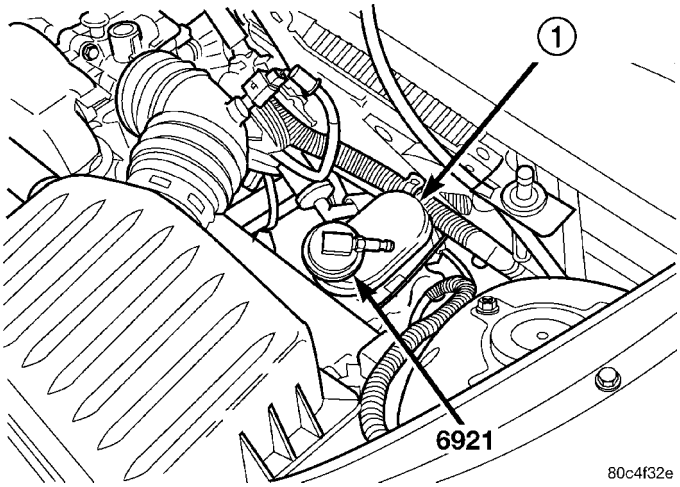

Fig. 2 Special Tool 6921

1 - MASTER CYLINDER FLUID RESERVOIR

(2) Attach Bleeder Tank, Special Tool C-3496-B, or an equivalent, to the adapter on the master cylinder.

(3) Attach a clear plastic hose to the bleeder screw and feed the hose into a clear jar containing enough fresh brake fluid to submerge the end of the hose (Fig. 1).

(4) Open the bleeder screw at least one full turn or more to obtain a steady stream of brake fluid.

(5) After approximately 4–8 ounces of fluid have been bled through the brake circuit and an air-free flow is maintained in the clear plastic hose and jar, close the bleeder screw.

(6) Repeat this procedure at all the remaining bleeder screws.

(7) Check the brake pedal travel. If pedal travel is excessive or has not been improved, some air may still be trapped in the system. Rebleed the brakes as necessary.

(8) Test drive the vehicle to verify the brakes are operating properly and pedal feel is correct.

BRAKE FLUID LEVEL SWITCH

DESCRIPTION

Two different master cylinders are used on this vehicle, but the brake fluid level switch is mounted similarly though the center of the fluid reservoir in both (Fig. 3). Early production PT27 (convertible) use master cylinders supplied by Bosch. Normal production vehicles (PT27 and PT44) use master cylinders supplied by Continental Teves.

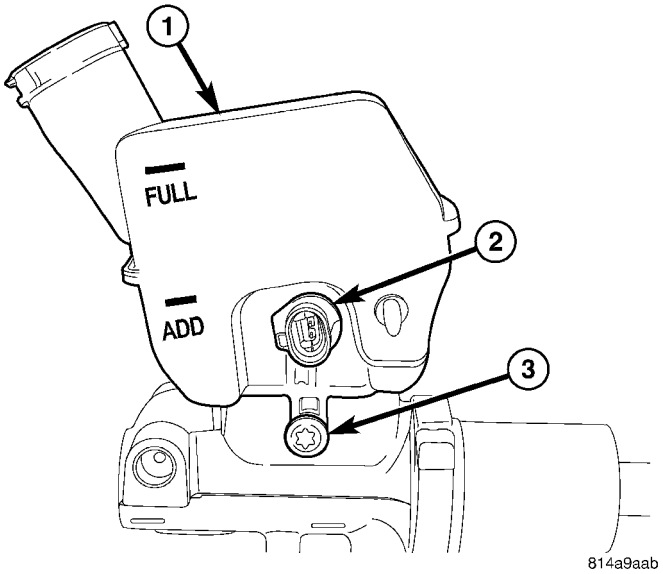

Fig. 3 Reservoir Mounting Screw

1 - RESERVOIR
2 - BRAKE FLUID LEVEL SWITCH
3 - RESERVOIR MOUNTING SCREW

REMOVAL

NOTE: Before proceeding, (Refer to 5 - BRAKES - WARNING) (Refer to 5 - BRAKES - CAUTION).

(1) Remove the vehicle wiring harness connector from brake fluid level switch in master cylinder brake fluid reservoir (Fig. 4).

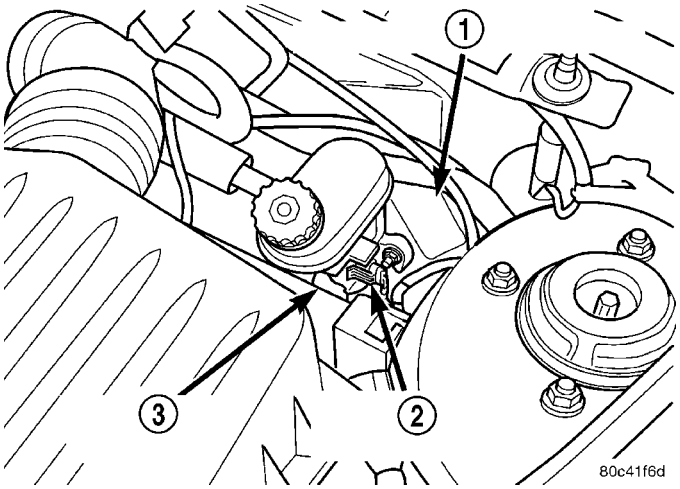

Fig. 4 Master Cylinder

1 - POWER BRAKE BOOSTER
2 - BRAKE FLUID LEVEL SWITCH
3 - MASTER CYLINDER

(2) Push together the retaining tabs holding the brake fluid level switch in place in the brake fluid reservoir (Fig. 5) (Fig. 6).

(3) Pull the brake fluid level switch out the opposite side of the reservoir.

BRAKE FLUID LEVEL SWITCH (Continued)

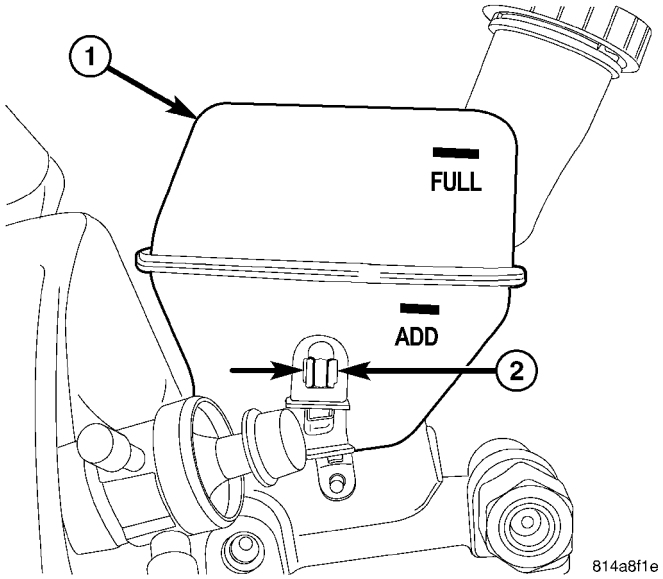

Fig. 6 Fluid Level Switch Retaining Tabs - Continental Teves

1 - RESERVOIR
2 - FLUID LEVEL SWITCH RETAINING TABS

INSTALLATION

(1) Align the brake fluid level switch with its mounting hole on the left side of the master cylinder brake fluid reservoir. Push the switch into the fluid reservoir until the switch retaining tabs are expanded on the other side of the reservoir, locking it in place (Fig. 5) (Fig. 6).

(2) Connect the brake fluid level switch wiring connector (Fig. 4).

HYDRAULIC/MECHANICAL

DESCRIPTION

DESCRIPTION - DISC BRAKES (FRONT)

Each front disc brake assembly consists of the following components (Fig. 7):

- Caliper - single-piston, floating type
- Caliper adapter
- Shoe and lining assemblies
- Rotor

The caliper is a one-piece casting with the inboard side containing a single piston cylinder bore. The front disc brake caliper piston, is manufactured from a phenolic compound. The outside diameter of the caliper piston is 57 mm.

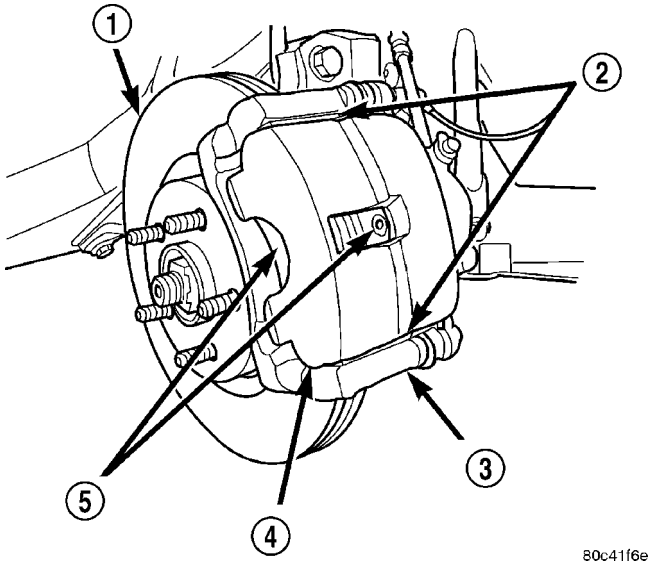

Fig. 7 Front Disc Brakes

1 - BRAKE ROTOR
2 - ABUTMENT SHIMS
3 - DISC BRAKE ADAPTER
4 - CALIPER
5 - BRAKE SHOES (PADS)

A square-cut rubber piston seal is located in a machined groove in the caliper cylinder bore. This seal provides a hydraulic seal between the piston and the cylinder wall (Fig. 8).

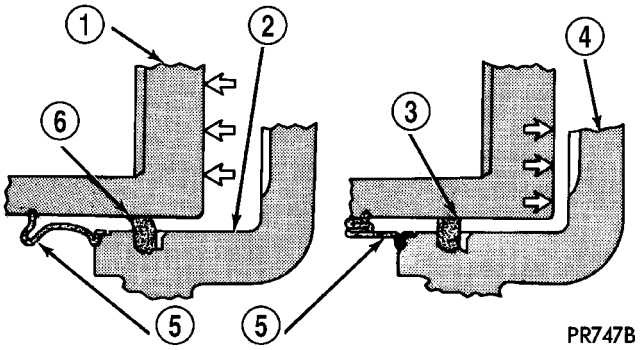

Fig. 8 Piston Seal Function

1 - PISTON
2 - CYLINDER BORE
3 - PISTON SEAL BRAKE PRESSURE OFF
4 - CALIPER HOUSING
5 - DUST BOOT
6 - PISTON SEAL BRAKE PRESSURE ON

A rubber dust boot is installed in a groove in cylinder bore opening and in a groove in the piston (Fig. 9). The boot prevents contamination in the bore area.

HYDRAULIC/MECHANICAL (Continued)

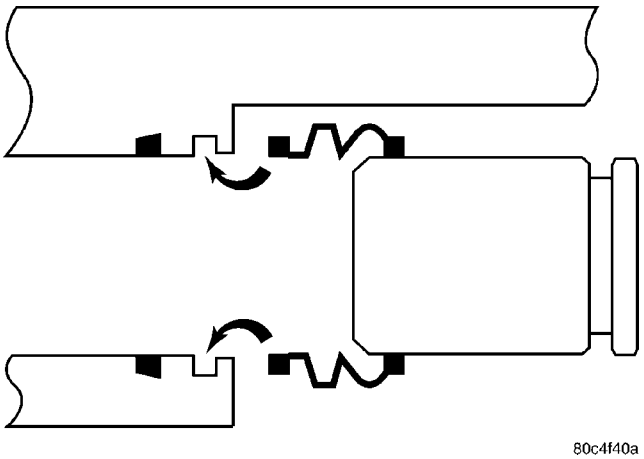

Fig. 9 Piston Boot Installation

The caliper is mounted to the caliper adapter using two guide pin bolts. These bolts thread into two guide pins, slid into the adapter (Fig. 10). The pins are lubricated and have boots to seal them in place in the adapter.

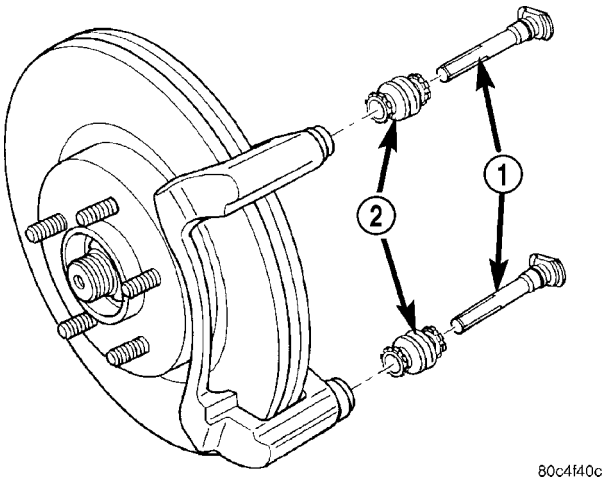

Fig. 10 Adapter, Boots And Pins

1 - PINS
2 - BOOTS

The disc brake caliper adapter is fastened to the steering knuckle using two bolts (Fig. 11).

The machined abutments on the adapter position the brake shoes and caliper. There are two brake shoes, sometimes referred to as pads, per disc brake. One shoe is placed on each side of the brake rotor (Fig. 12). Two abutment shims (upper and lower) ride between the shoes and adapter. The shoes have springs permanently attached to them to help maintain a distance between the shoes and the caliper. When brake shoes are replaced, only brake shoes meeting the original equipment manufacturer (OEM) formulation (such as Mopar® replacement parts) should be used.

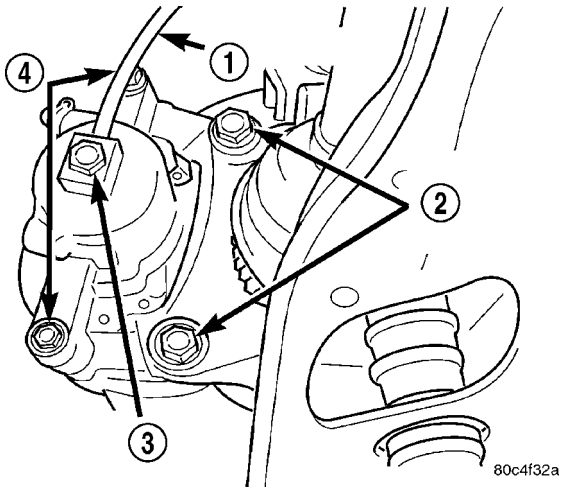

Fig. 11 Adapter Mounting

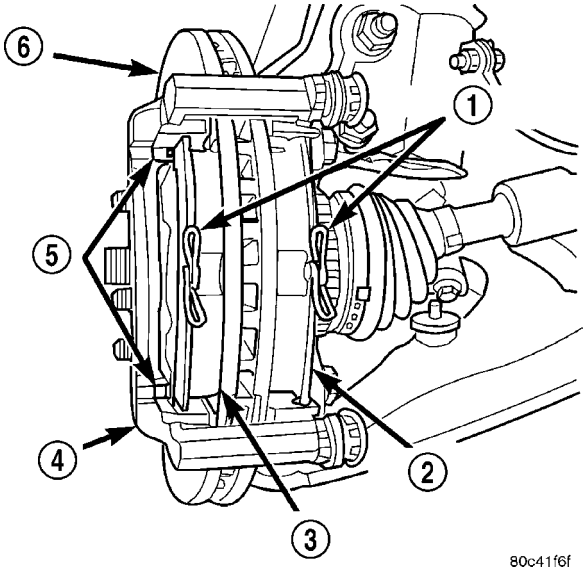

Fig. 12 Brake Shoes Mounted In Adapter

1 - SPRINGS
2 - INBOARD SHOE
3 - OUTBOARD SHOE
4 - DISC BRAKE ADAPTER
5 - ABUTMENT SHIMS
6 - BRAKE ROTOR

Front disc brakes are equipped with audible wear indicators on the inboard brake shoes.

Each front brake rotor is vented to help cool it during and after brake applications. It is mounted on the studs of the front wheel bearing hub.

HYDRAULIC/MECHANICAL (Continued)

This vehicle has an optional performance brake system. The sales code for this system is BR4. Although similar in appearance to the other front disc brake systems available (BRB and BRK (Disc/Drum combination) and BRT (Disc/Disc combination)), this system features heavy duty wheel brake components. BR4 front disc brakes utilize brake rotors that have a pad contact surface approximately 5 mm thicker and brake calipers (and adapters) to accommodate that additional width. The BR4 calipers and rotors can be easily identified. Each BR4 brake caliper is marked “Turbo” while each rotor has a recessed machined area near the hub center (Fig. 13) (Fig. 14).

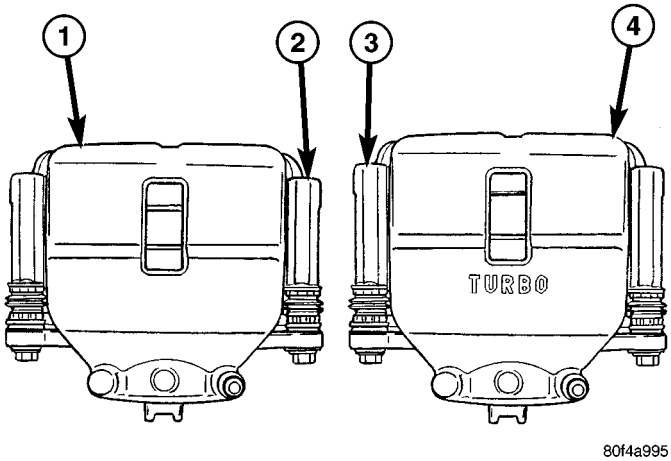

Fig. 13 Standard And BR4 Brake Calipers

1 - BRB/BRT FRONT BRAKE CALIPER
2 - ADAPTER
3 - ADAPTER
4 - BR4 FRONT BRAKE CALIPER

NOTE: Special care should be taken to assure that the correct caliper is used only with the correct rotor.

4 - BR4 PERFORMANCE BRAKE ROTOR
5 - INDENTIFYING MACHINED AREA

DESCRIPTION - DISC BRAKES (REAR)

Rear disc brakes are optional equipment on some models of this vehicle (Fig. 15). The rear disc brakes are similar to the front disc brakes; however, there are several distinctive features that require different service procedures. Each rear disc brake consists of the following components:

- Caliper - single-piston, floating type
- Caliper adapter
- Shoe and lining assemblies
- Rotor - drum-in-hat type

Vehicles are equipped with a one piece caliper assembly that has a 36 mm (1.42 in.) piston and uses a solid non-vented 270 mm (10.63 in.) brake rotor.

The caliper assembly for all applications floats on rubber bushings using internal metal sleeves that are attached to the adapter using threaded guide pin bolts.

The brake caliper adapter is mounted to the rear suspension spindle. The adapter is used to mount the disc brake caliper to the vehicle (Fig. 15). The adapter has two machined abutments which are used to position and align the caliper and brake shoes for movement inboard and outboard.

When brake shoes, sometimes referred to as pads, are replaced, only brake shoes meeting the original equipment manufacturer (OEM) formulation (such as Mopar® replacement parts) should be used.

The adapter also mounts the parking brake shoes and actuating cables to the vehicle. All vehicles equipped with rear disc brakes have a small duo-servo drum brake mounted to the caliper adapter. This is part of the parking brake system. (Refer to 5 - BRAKES/PARKING BRAKE - DESCRIPTION)

This vehicle has an optional performance brake system. The sales code for this system is BR4. Although similar in appearance to the BRT (Disc/

Disc combination), this system features heavy duty wheel brake components. BR4 rear disc brakes utilize brake rotors that have a pad contact surface approximately 3 mm thicker. To accommodate that additional width, instead of using wider calipers as the front brakes do, each rear brake shoe metal backing plate is 1.5 mm thinner than that of the standard BRT rear disc brakes (Fig. 16). BR4 brake rotors can be easily identified by the recessed machined area near the hub center (Fig. 17).

5 - INDENTIFYING MACHINED AREA

NOTE: Special care should be taken to assure that the correct brake shoes are used only with the correct rotor.

DESCRIPTION - DRUM BRAKES (REAR)

All vehicles with rear drum brakes are equipped with 228mm rear drum brakes sales code designated BRB or BRK. The drum brakes are all two-shoe, internal-expanding type with an automatic adjuster screw.

The rear drum brake system consists of these major components (Fig. 18) as well as the attaching hardware:

- Drum
- Shoes
- Support Plate
- Wheel Cylinder

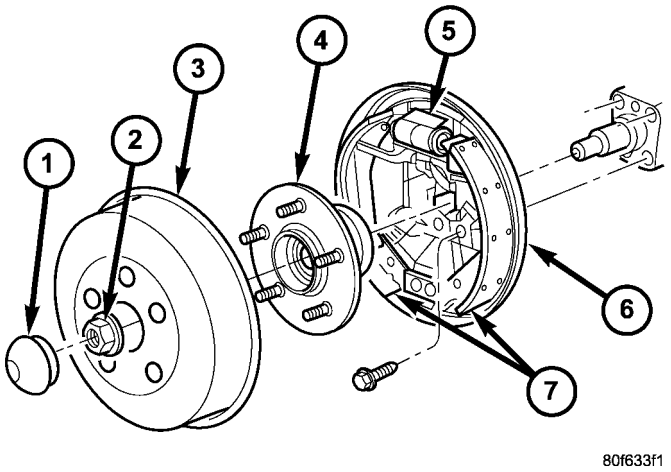

Fig. 18 Drum Brakes

1 - DUST CAP
2 - NUT
3 - DRUM
4 - HUB AND BEARING
5 - WHEEL CYLINDER
6 - SUPPORT PLATE
7 - BRAKE SHOES

DIAGNOSIS AND TESTING - DRUM BRAKE AUTOMATIC ADJUSTER

To properly test the drum brake automatic adjuster, the aide of a helper inside the vehicle to apply the brakes will be necessary.

(1) Raise the vehicle. (Refer to LUBRICATION & MAINTENANCE/HOISTING - STANDARD PROCEDURE).

(2) Remove the access plug from the rear adjustment slot in each brake support plate.

(3) Insert a thin screwdriver in the adjustment slot and push back the adjustment lever. With the lever in this position, back the star wheel adjustment off approximately 10 notches. This will eliminate the possibility that the brake is at full adjustment, and can be adjusted no further.

(4) Remove the screwdriver from the adjustment slot.

(5) Watch the star wheel through the adjustment slot, while a helper applies the brake pedal. As the brake shoes apply, the adjustment lever should move downward, turning the star wheel. A definite rotation of the adjuster star wheel can be observed if the automatic adjuster is working properly.

If the star wheel does not move as indicated, the brake drum needs to be removed and further inspection of the rear brakes is necessary.

(6) If the star wheel is operating properly, readjust the brakes. (Refer to 5 - BRAKES/HYDRAULIC/MECHANICAL/BRAKE PADS/SHOES - ADJUSTMENTS).

(7) Reinstall the adjustment slot access plug.

(8) Lower the vehicle.

BRAKE LINES

DESCRIPTION - BRAKE TUBES AND HOSES

The brake tubes are steel with a corrosion-resistant nylon coating applied to the external surfaces. The flex hoses are made of reinforced rubber with fittings at each end.

OPERATION - BRAKE TUBES AND HOSES

The purpose of the brake tubes and flex hoses is to transfer brake fluid pressure, developed by the master cylinder to the brakes at each wheel of the vehicle. The flex hoses connect the chassis brake tubes which are mounted to the vehicle's underbody to the brake at each wheel, allowing for movement of the vehicle's suspension.

INSPECTION - BRAKE TUBES AND HOSES

Flexible rubber hose is used at both front and rear brakes. Inspection of brake hoses should be performed whenever the brake system is serviced and every 7,500 miles or 12 months, whichever comes first (every engine oil change). Inspect hydraulic brake hoses for severe surface cracking, scuffing, worn spots or physical damage. If the fabric casing of the rubber hose becomes exposed due to cracks or abrasions in the rubber hose cover, the hose should be replaced immediately. Eventual deterioration of the hose can take place with possible burst failure. Faulty installation can cause twisting, resulting in wheel, tire, or chassis interference.

The steel brake tubing should be inspected periodically for evidence of corrosion, physical damage or contact with moving or hot components of the vehicle.

BRAKE PADS/SHOES - FRONT

REMOVAL

NOTE: Before proceeding, (Refer to 5 - BRAKES - WARNING) (Refer to 5 - BRAKES - CAUTION).

(1) Raise the vehicle. (Refer to LUBRICATION & MAINTENANCE/HOISTING - STANDARD PROCEDURE)

NOTE: Perform Step 2 through Step 5 on each side of the vehicle to complete shoe set removal.

(2) Remove the front tire and wheel assembly.

(3) Remove the two brake caliper guide pin bolts (Fig. 19).

BRAKE PADS/SHOES - FRONT (Continued)

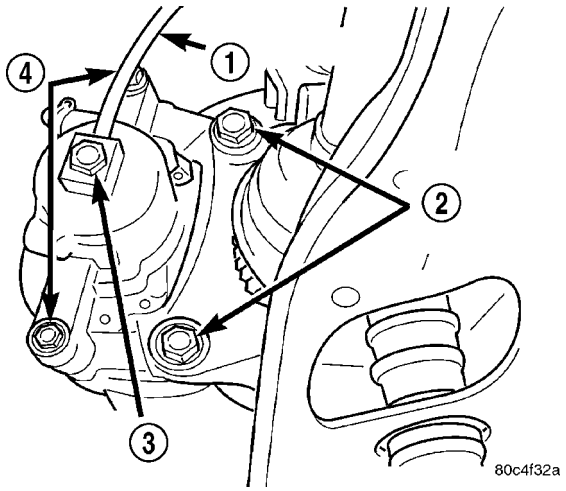

Fig. 19 Brake Caliper Mounting (Typical)

1 - BRAKE HOSE
2 - ADAPTER MOUNTING BOLTS
3 - BANJO BOLT
4 - CALIPER GUIDE PIN BOLTS

(4) Remove the disc brake caliper from the disc brake adapter and hang out of the way using wire or a bungee cord. Use care not to overextend the brake hose when doing this.

(5) Remove the brake shoes from the disc brake caliper adapter (Fig. 20).

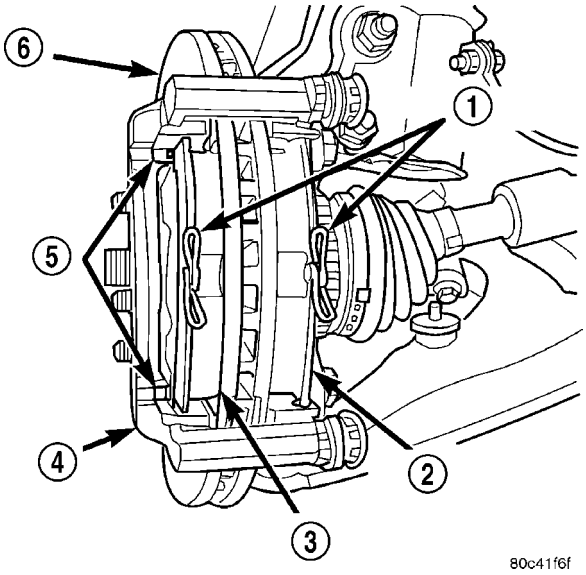

Fig. 20 Brake Shoes Mounted In Adapter

CLEANING - DISC BRAKE SHOES

WARNING: DUST AND DIRT ACCUMULATING ON BRAKE PARTS DURING NORMAL USE MAY CONTAIN ASBESTOS FIBERS FROM PRODUCTION OR AFTERMARKET BRAKE LININGS. BREATHING EXCESSIVE CONCENTRATIONS OF ASBESTOS FIBERS CAN CAUSE SERIOUS BODILY HARM. EXERCISE CARE WHEN SERVICING BRAKE PARTS. DO NOT SAND OR GRIND BRAKE LINING UNLESS EQUIPMENT USED IS DESIGNED TO CONTAIN THE DUST RESIDUE. DO NOT CLEAN BRAKE PARTS WITH COMPRESSED AIR OR BY DRY BRUSHING. CLEANING SHOULD BE DONE BY DAMPENING THE BRAKE COMPONENTS WITH A FINE MIST OF WATER, THEN WIPING THE BRAKE COMPONENTS CLEAN WITH A DAMPENED CLOTH. DISPOSE OF CLOTH AND ALL RESIDUE CONTAINING ASBESTOS FIBERS IN AN IMPERMEABLE CONTAINER WITH THE APPROPRIATE LABEL. FOLLOW PRACTICES PRESCRIBED BY THE OCCUPATIONAL SAFETY AND HEALTH ADMINISTRATION (OSHA) AND THE ENVIRONMENTAL PROTECTION AGENCY (EPA) FOR THE HANDLING, PROCESSING, AND DISPOSING OF DUST OR DEBRIS THAT MAY CONTAIN ASBESTOS FIBERS.

INSPECTION - DISC BRAKE SHOES

Visually inspect brake shoes (pads) for uneven lining wear. Also inspect for excessive lining deterioration. Check the clearance between the tips of the wear indicators on the shoes (if equipped) and the brake rotors.

If a visual inspection does not adequately determine the condition of the lining, a physical check will be necessary. To check the amount of lining wear, remove the disc brake shoes from the calipers.

Measure each brake shoe. The combined brake shoe and its lining material thickness should be measured at its thinnest point.

- For front disc brake shoes, when a set of brake shoes are worn to a thickness of approximately 7.95 mm (5/16 inch), they should be replaced.
- For rear disc brake shoes, when a set of brake shoes are worn to a thickness of approximately 9.0 mm (3/8 inch), they should be replaced.
- Typically, if front shoes are worn out, both fronts and rears need to be replaced. Make sure to check rears.

Replace **both** disc brake shoes (inboard and outboard) on each caliper. It is necessary to replace the shoes on the opposite side of the vehicle as well as the shoes failing inspection.

BRAKE PADS/SHOES - FRONT (Continued)

If the brake shoe assemblies do not require replacement, be sure to reinstall the brake shoes in the original position they were remove from.

INSTALLATION

NOTE: Perform Step 1 through Step 5 on each side of the vehicle to complete shoe set installation, then proceed to Step 6.

NOTE: Inboard brake shoes are not identical side-to-side. This is due to placement of the audible wear indicator on the end of each inboard shoe. Make sure that the audible wear indicators are placed toward the top when the inboard shoes are installed on each side of the vehicle.

(1) Place the brake shoes in the abutment shims clipped into the disc brake caliper adapter as shown (Fig. 20). Place the shoe with the wear indicator attached on the inboard side.

(2) Completely retract the caliper piston back into the bore of the caliper.

CAUTION: Use care when installing the caliper onto the disc brake adapter to avoid damaging the boots on the caliper guide pins.

(3) Install the disc brake caliper over the brake shoes on the brake caliper adapter. Make sure the springs on the shoes do not get caught in the hole formed into the center of the caliper housing.

(4) Align the caliper guide pin bolt holes with the guide pins. Install the caliper guide pin bolts and tighten them to a torque of 35 N·m (26 ft. lbs.) (Fig. 19).

(5) Install the tire and wheel assembly. Tighten the wheel mounting nuts to a torque of 135 N·m (100 ft. lbs.).

(6) Lower the vehicle.

(7) Pump the brake pedal several times before moving the vehicle to set the shoes to the brake rotor.

(8) Check and adjust the brake fluid level as necessary.

(9) Road test the vehicle and make several stops to wear off any foreign material on the brakes and to seat the brake shoes.

BRAKE PADS/SHOES - REAR DISC

REMOVAL

NOTE: Before proceeding, (Refer to 5 - BRAKES - WARNING) (Refer to 5 - BRAKES - CAUTION).

(1) Raise the vehicle. (Refer to LUBRICATION & MAINTENANCE/HOISTING - STANDARD PROCEDURE)

(2) Remove both rear tire and wheel assemblies from vehicle.

NOTE: Perform Step 3 through Step 7 on each side of the vehicle to complete shoe set removal.

NOTE: In some cases, it may be necessary to retract the caliper piston in its bore a small amount in order to provide sufficient clearance between the shoes and the rotor to easily remove the caliper from the knuckle. This can usually be accomplished before the guide pin bolts are removed, by grasping the rear of the caliper and pulling outward working with the guide pins, thus retracting the piston. Never push on the piston directly as it may get damaged.

(3) Remove the two caliper guide pin bolts (Fig. 21).

BRAKE PADS/SHOES - REAR DISC (Continued)

CLEANING - DISC BRAKE SHOES

WARNING: DUST AND DIRT ACCUMULATING ON BRAKE PARTS DURING NORMAL USE MAY CONTAIN ASBESTOS FIBERS FROM PRODUCTION OR AFTERMARKET BRAKE LININGS. BREATHING EXCESSIVE CONCENTRATIONS OF ASBESTOS FIBERS CAN CAUSE SERIOUS BODILY HARM. EXERCISE CARE WHEN SERVICING BRAKE PARTS. DO NOT SAND OR GRIND BRAKE LINING UNLESS EQUIPMENT USED IS DESIGNED TO CONTAIN THE DUST RESIDUE. DO NOT CLEAN BRAKE PARTS WITH COMPRESSED AIR OR BY DRY BRUSHING. CLEANING SHOULD BE DONE BY DAMPENING THE BRAKE COMPONENTS WITH A FINE MIST OF WATER, THEN WIPING THE BRAKE COMPONENTS CLEAN WITH A DAMPENED CLOTH. DISPOSE OF CLOTH AND ALL RESIDUE CONTAINING ASBESTOS FIBERS IN AN IMPERMEABLE CONTAINER WITH THE APPROPRIATE LABEL. FOLLOW PRACTICES PRESCRIBED BY THE OCCUPATIONAL SAFETY AND HEALTH ADMINISTRATION (OSHA) AND THE ENVIRONMENTAL PROTECTION AGENCY (EPA) FOR THE HANDLING, PROCESSING, AND DISPOSING OF DUST OR DEBRIS THAT MAY CONTAIN ASBESTOS FIBERS.

INSPECTION - DISC BRAKE SHOES

Visually inspect brake shoes (pads) for uneven lining wear. Also inspect for excessive lining deterioration. Check the clearance between the tips of the wear indicators on the shoes (if equipped) and the brake rotors.

If a visual inspection does not adequately determine the condition of the lining, a physical check will be necessary. To check the amount of lining wear, remove the disc brake shoes from the calipers.

Measure each brake shoe. The combined brake shoe and its lining material thickness should be measured at its thinnest point.

- For front disc brake shoes, when a set of brake shoes are worn to a thickness of approximately 7.95 mm (5/16 inch), they should be replaced.
- For rear disc brake shoes, when a set of brake shoes are worn to a thickness of approximately 9.0 mm (3/8 inch), they should be replaced.
- Typically, if front shoes are worn out, both fronts and rears need to be replaced. Make sure to check rears.

Replace **both** disc brake shoes (inboard and outboard) on each caliper. It is necessary to replace the shoes on the opposite side of the vehicle as well as the shoes failing inspection.

If the brake shoe assemblies do not require replacement, be sure to reinstall the brake shoes in the original position they were remove from.

INSTALLATION

CAUTION: When installing new brake components, be sure to use correct parts. Parts designed for BR4 Performance Brake System must not be mixed with other brake systems. These parts, similar in appearance, can be easily identified (Fig. 16) (Fig. 17). (Refer to 5 - BRAKES/HYDRAULIC/MECHANICAL - DESCRIPTION - DISC BRAKES (REAR))

NOTE: Perform Step 1 through Step 7 on each side of the vehicle to complete shoe set installation, then proceed to Step 8.

(1) Completely retract the caliper piston back into piston bore of the caliper. This is required to gain the necessary shoe-to-rotor clearance for the caliper installation onto the steering knuckle.

(2) Install the inboard brake shoe into the caliper piston by firmly pressing the shoe in with the thumbs (Fig. 25). Be sure the inboard brake shoe is positioned squarely against the face of the caliper piston.

(3) Slide the outboard brake shoe onto the caliper assembly (Fig. 24). Be sure the retaining clip is squarely seated in the depressed areas on the caliper.

(4) Lubricate both adapter caliper slide abutments with a liberal amount of Mopar® Multipurpose Lubricant, or an equivalent.

CAUTION: Use care when installing the caliper assembly onto adapter so the guide pin bushings and sleeves do not get damaged by the mounting bosses on adapter.

(5) Starting with the lower end, carefully lower the caliper and brake shoes over the brake rotor and catch the caliper's bottom edge behind the caliper slide abutment (Fig. 22). Rotate the top of the caliper into mounting position on the adapter.

CAUTION: Extreme caution should be taken not to cross thread the caliper guide pin bolts when they are installed.

(6) Carefully install the caliper guide pin bolts (Fig. 21), then tighten them to a torque of 22 N·m (192 in. lbs.).

(7) Install the tire and wheel assembly. Tighten the wheel mounting nuts to a torque of 135 N·m (100 ft. lbs.).

(8) Lower the vehicle.

BRAKE PADS/SHOES - REAR DISC (Continued)

(9) Pump the brake pedal several times to ensure the vehicle has a firm brake pedal before moving the vehicle.

(10) Road test the vehicle and make several stops to wear off any foreign material on the brakes and to seat the brake shoes.

BRAKE PADS/SHOES - REAR DRUM

REMOVAL

NOTE: Before proceeding, (Refer to 5 - BRAKES - WARNING) (Refer to 5 - BRAKES - CAUTION).

NOTE: Make sure parking brake is in “released” position before raising vehicle.

(1) Raise and support vehicle. (Refer to LUBRICATION & MAINTENANCE/HOISTING - STANDARD PROCEDURE)

(2) Remove both rear tire and wheel assemblies from vehicle.

(3) Remove brake drums from both sides of vehicle (Fig. 26). (Refer to 5 - BRAKES/HYDRAULIC/MECHANICAL/DRUM - REMOVAL)

NOTE: Perform Step 4 through Step 12 on each side of the vehicle to complete shoe set removal. It may be easier to install the new components on the first side of the vehicle before disassembling the opposite side so it may be used as a reference guide for proper installation. (Refer to 5 - BRAKES/HYDRAULIC/MECHANICAL/BRAKE PADS/SHOES - REAR DRUM - INSTALLATION)

(4) Remove hub and bearing dust cap (Fig. 26).

(5) Remove hub and bearing retaining nut, then slide hub and bearing off spindle (Fig. 26).

(6) Compress cable return spring, then remove parking brake cable from parking brake lever (Fig. 27).

(7) Remove lower return spring (Fig. 28).

(8) Compress and remove shoe hold-down spring clips (Fig. 28).

(9) Remove both shoes and remaining parts as an assembly from anchor and wheel cylinder (Fig. 28).

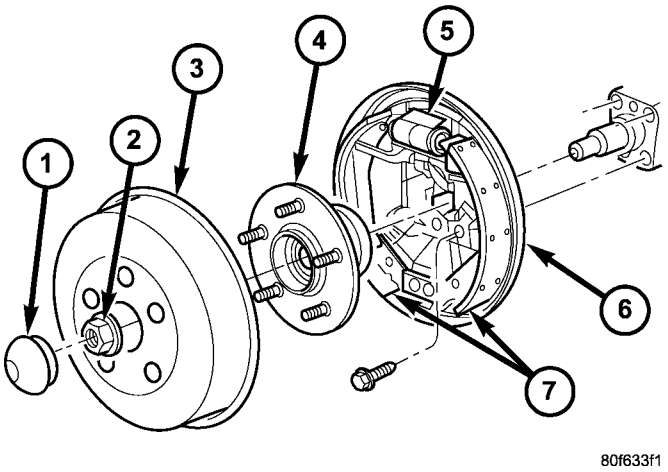

Fig. 26 Drum Brakes

1 - DUST CAP
2 - NUT
3 - DRUM
4 - HUB AND BEARING
5 - WHEEL CYLINDER
6 - SUPPORT PLATE
7 - BRAKE SHOES

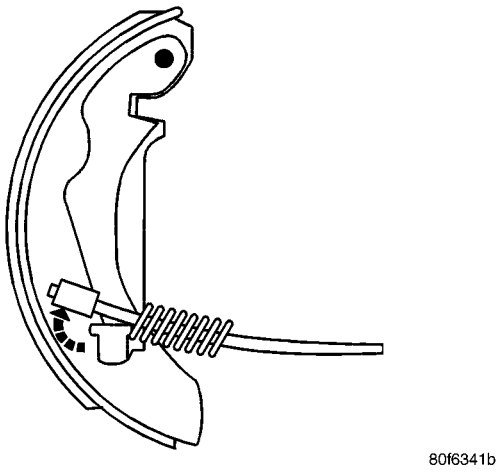

Fig. 27 Cable Removal From Lever

BRAKE PADS/SHOES - REAR DRUM (Continued)

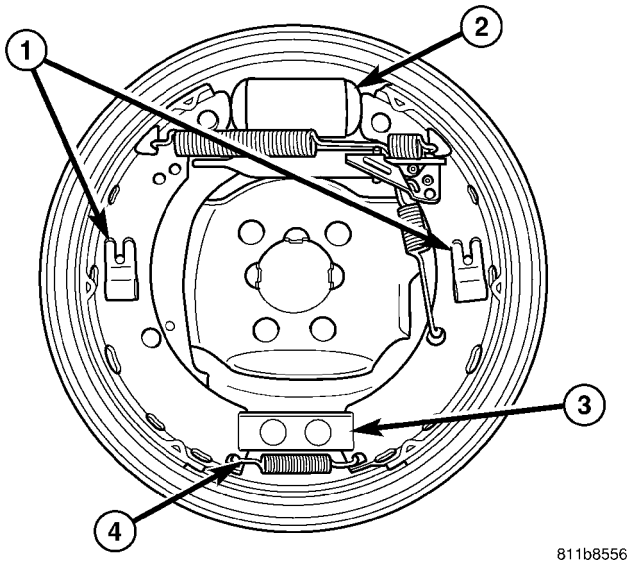

Fig. 28 Shoes Mounted To Support Plate

1 - HOLD-DOWN SPRING CLIPS
2 - WHEEL CYLINDER
3 - ANCHOR
4 - LOWER RETURN SPRING

(10) Remove adjuster spring from leading shoe and lever pawl (Fig. 29).

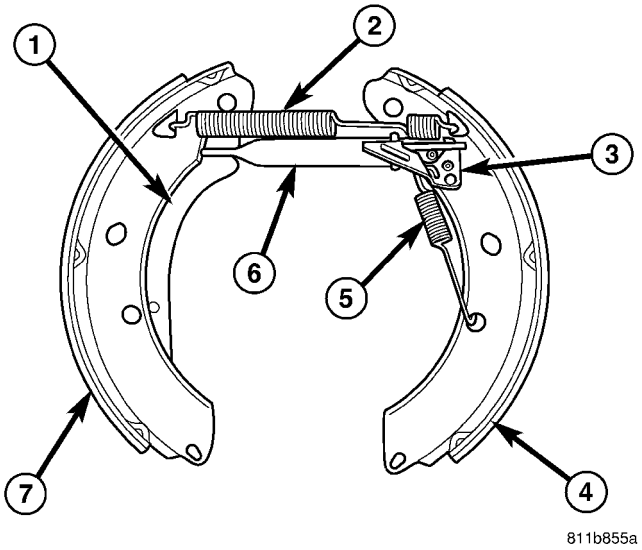

Fig. 29 Bench Assembled Shoes (Right Side Shown)

1 - LEVER
2 - UPPER RETURN SPRING
3 - LEVER PAWL
4 - LEADING SHOE
5 - ADJUSTER SPRING
6 - ADJUSTER
7 - TRAILING SHOE

(11) Remove lever pawl from pivot on leading shoe and slide out from under adjuster.

(12) Remove adjuster and upper spring from shoes. (Fig. 29).

CLEANING

WARNING: DUST AND DIRT ACCUMULATING ON BRAKE PARTS DURING NORMAL USE MAY CONTAIN ASBESTOS FIBERS FROM PRODUCTION OR AFTERMARKET BRAKE LININGS. BREATHING EXCESSIVE CONCENTRATIONS OF ASBESTOS FIBERS CAN CAUSE SERIOUS BODILY HARM. EXERCISE CARE WHEN SERVICING BRAKE PARTS. DO NOT SAND OR GRIND BRAKE LINING UNLESS EQUIPMENT USED IS DESIGNED TO CONTAIN THE DUST RESIDUE. DO NOT CLEAN BRAKE PARTS WITH COMPRESSED AIR OR BY DRY BRUSHING. CLEANING SHOULD BE DONE BY DAMPENING THE BRAKE COMPONENTS WITH A FINE MIST OF WATER, THEN WIPING THE BRAKE COMPONENTS CLEAN WITH A DAMPENED CLOTH. DISPOSE OF CLOTH AND ALL RESIDUE CONTAINING ASBESTOS FIBERS IN AN IMPERMEABLE CONTAINER WITH THE APPROPRIATE LABEL. FOLLOW PRACTICES PRESCRIBED BY THE OCCUPATIONAL SAFETY AND HEALTH ADMINISTRATION (OSHA) AND THE ENVIRONMENTAL PROTECTION AGENCY (EPA) FOR THE HANDLING, PROCESSING, AND DISPOSING OF DUST OR DEBRIS THAT MAY CONTAIN ASBESTOS FIBERS.

INSPECTION

Rear brake shoe lining should show contact across the entire width of the lining and also from the heel to the toe of the lining. Replace the shoes if noted otherwise.

Brake shoes with lack of contact at the toe or heel of the brake shoe lining may be improperly ground.

Clean and inspect the brake support plate and shoe adjuster screw. Apply a thin coat of Mopar® Multi-Purpose Grease or equivalent to the threads of the self-adjuster. Replace the adjuster screw if it is corroded.

NOTE: Adjuster screws are different side-to-side. Left side adjuster screws have left-hand threads and right side adjuster screws have right-handed threads.

If the old brake shoe return or hold down springs have overheated or are damaged, replace them. Overheating indications are paint discoloration or distorted end coils.

BRAKE PADS/SHOES - REAR DRUM (Continued)

INSTALLATION

NOTE: Perform Step 1 through Step 11 on each side of vehicle to complete shoe set installation, then proceed to Step 12.

(1) Lubricate six shoe contact areas on support plate and anchor using Mopar® Brake Lubricant or equivalent (Fig. 30).

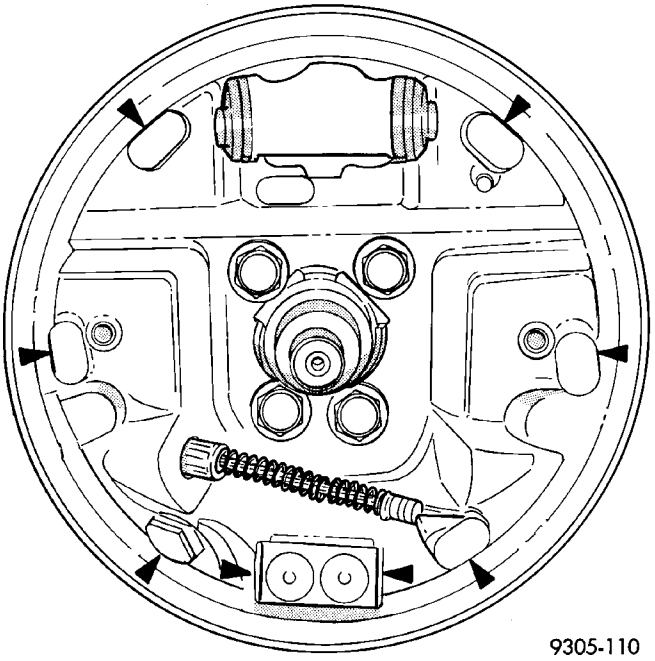

Fig. 30 Shoe Contact Areas on Support Plate

(2) Before installing shoes on vehicle, perform the following on the bench:

(a) Place one leading and one trailing shoe on bench (trailing shoe has parking brake lever attached to it).

(b) Install adjuster and upper spring (Fig. 29).

(c) Slide lever pawl under adjuster and onto pivot on leading shoe.

(d) Install adjuster spring between leading shoe and lever pawl (Fig. 29).

(3) Install pre-assembled brake shoe assembly over wheel cylinder and anchor on brake support plate (Fig. 28).

(4) Install both shoe hold-down pins from rear (Fig. 31), through support plate and shoes.

(5) Compress and install shoe hold-down spring clips on pins (Fig. 28).

(6) Install lower return spring (Fig. 28).

(7) Compress parking brake cable return spring, then install cable on parking brake lever (Fig. 32). Release spring guiding it beneath retaining tab on lever.

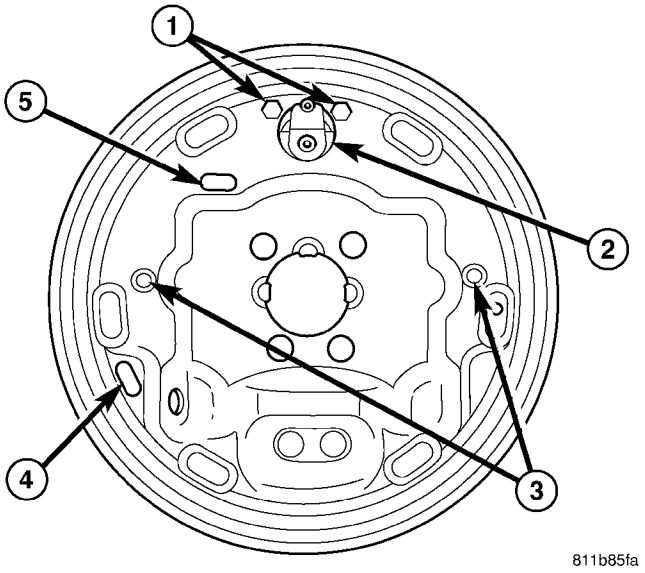

Fig. 31 Rear View Of Brake Support Plate (Right Side Shown)

1 - WHEEL CYLINDER MOUNTING BOLTS
2 - WHEEL CYLINDER
3 - SHOE HOLD-DOWN PINS
4 - SHOE WEAR INSPECTION HOLE
5 - ADJUSTER ACCESS HOLE

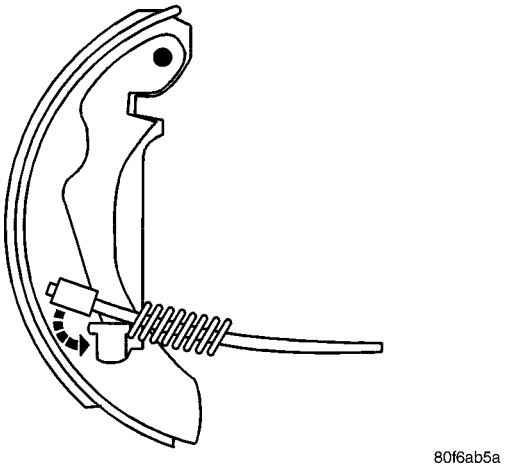

Fig. 32 Cable Installation To Lever

(8) Slide hub and bearing onto spindle (Fig. 26). Install retaining nut and tighten to 217 N·m (160 ft. lbs.) torque.

(9) Install hub and bearing dust cap (Fig. 26).

(10) Adjust brake shoes to drum diameter using brake shoe gauge. (Refer to 5 - BRAKES/HYDRAULIC/MECHANICAL/BRAKE PADS/SHOES - ADJUSTMENTS)

(11) Install brake drum (Fig. 26). (Refer to 5 - BRAKES/HYDRAULIC/MECHANICAL/DRUM - INSTALLATION)

BRAKE PADS/SHOES - REAR DRUM (Continued)

(12) Install both tire and wheel assemblies. Tighten wheel mounting nuts to 135 N·m (100 ft. lbs.) torque.

(13) Slowly rotate wheels and verify that brake drums **lightly** drag on shoes.

(14) Lower vehicle.

(15) Road test vehicle stopping in both forward and reverse directions. Automatic-adjuster will continue to adjust brakes as necessary during road test.

ADJUSTMENTS

ADJUSTMENT - DRUM BRAKE SHOES

NOTE: Before proceeding, (Refer to 5 - BRAKES - WARNING) (Refer to 5 - BRAKES - CAUTION).

(1) Verify the parking brake lever is in the fully released position.

(2) Raise the vehicle. (Refer to LUBRICATION & MAINTENANCE/HOISTING - STANDARD PROCEDURE)

NOTE: Perform the following steps on each rear drum brake assembly.

(3) Remove the tire and wheel assembly from the vehicle.

(4) Remove the brake drum. (Refer to 5 - BRAKES/HYDRAULIC/MECHANICAL/DRUM - REMOVAL)

(5) Using a brake shoe gauge, Special Tool C-3919 or equivalent, measure the inside diameter of the brake drum (Fig. 33). Tighten the gauge set-screw at this measurement.

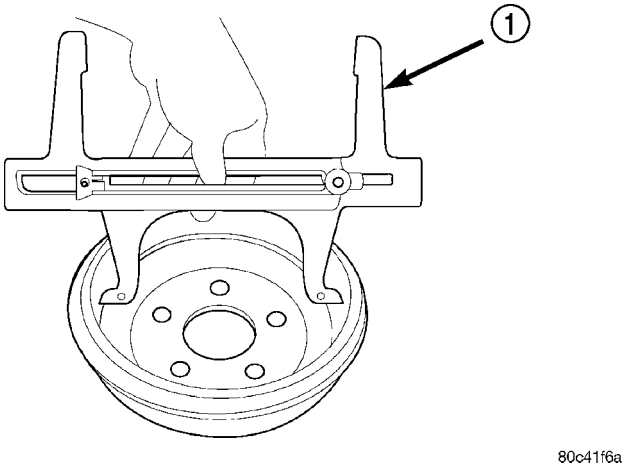

Fig. 33 Brake Drum Measurement

1 - BRAKE SHOE GAUGE

(6) Place the other side of the brake shoe gauge on the brake shoes as shown (Fig. 34).

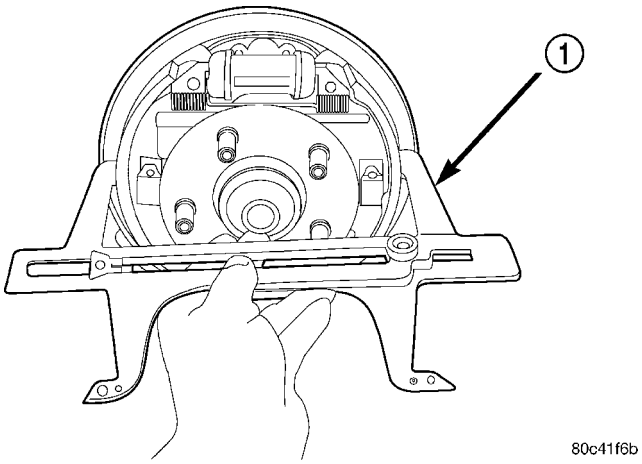

Fig. 34 Brake Shoe Measurement

1 - BRAKE SHOE GAUGE

(7) Adjust the shoe diameter to the setting on the gauge. To adjust the shoe diameter, turn the adjuster-screw star-wheel using a screwdriver inserted through the adjusting hole in the rear of the shoe support plate. Once the tip of the screwdriver contacts the star-wheel teeth, move the handle of tool downward using the support plate as a pivot to adjust the shoes outward.

(8) Once the shoe diameter is set, reinstall the brake drum.

(9) Turn the drum. A slight drag should be felt while rotating the drum.

(10) Install the tire and wheel assembly. Tighten the wheel mounting nuts to a torque of 135 N·m (100 ft. lbs.).

(11) After adjusting both rear drum brakes, lower the vehicle.

(12) Apply and release the parking brake lever one time after the adjustment process is completed so the parking brakes can readjust themselves to the new brake shoe adjustment.

(13) Road test vehicle stopping in both forward and reverse directions. Automatic-adjuster will continue to adjust brakes as necessary during road test.

DISC BRAKE CALIPER - FRONT

REMOVAL

NOTE: Before proceeding, (Refer to 5 - BRAKES - WARNING) (Refer to 5 - BRAKES - CAUTION).

(1) Using a brake pedal holding tool as shown (Fig. 35), depress the brake pedal past its first one inch of travel and hold it in this position. This will isolate the master cylinder from the brake hydraulic system

DISC BRAKE CALIPER - FRONT (Continued)

and will not allow the brake fluid to drain out of the master cylinder reservoir when the lines are opened.

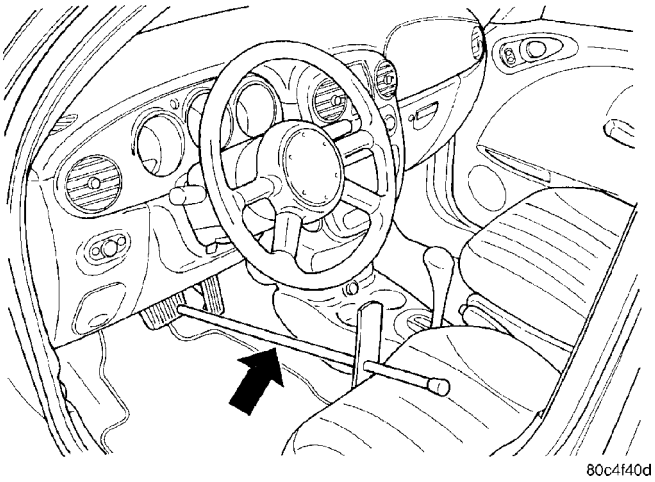

Fig. 35 Brake Pedal Holding Tool

(2) Raise the vehicle. (Refer to LUBRICATION & MAINTENANCE/HOISTING - STANDARD PROCEDURE)

(3) Remove the front tire and wheel assembly.

(4) Remove the banjo bolt connecting the brake hose to the brake caliper (Fig. 36). There are two washers (one on each side of the flex hose fitting) that will come off with the banjo bolt. Discard the washers.

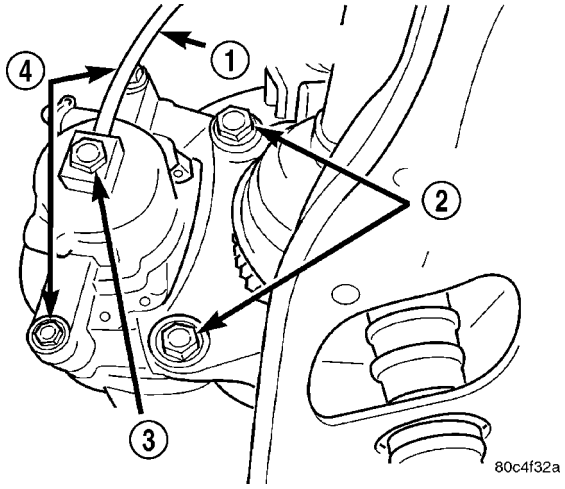

Fig. 36 Brake Caliper Mounting (Typical)

1 - BRAKE HOSE
2 - ADAPTER MOUNTING BOLTS
3 - BANJO BOLT
4 - CALIPER GUIDE PIN BOLTS

(5) Remove the two brake caliper guide pin bolts (Fig. 36).

(6) Remove the disc brake caliper from the disc brake adapter.

DISASSEMBLY

NOTE: Before disassembling the brake caliper, remove it from the vehicle. (Refer to 5 - BRAKES/HYDRAULIC/MECHANICAL/DISC BRAKE CALIPER - REMOVAL)

NOTE: Before disassembling the brake caliper, clean and inspect it. (Refer to 5 - BRAKES/HYDRAULIC/MECHANICAL/DISC BRAKE CALIPER - CLEANING) (Refer to 5 - BRAKES/HYDRAULIC/MECHANICAL/DISC BRAKE CALIPER - INSPECTION)

WARNING: UNDER NO CONDITION SHOULD HIGH PRESSURE AIR EVER BE USED TO REMOVE A PISTON FROM A CALIPER BORE. PERSONAL INJURY COULD RESULT FROM SUCH A PRACTICE.

CAUTION: Do not use excessive force when clamping caliper in vise. Excessive vise pressure will cause bore distortion.

(1) Mount the caliper in a vise equipped with protective jaws.

(2) Place a wooden block in the caliper as shown (Fig. 37).

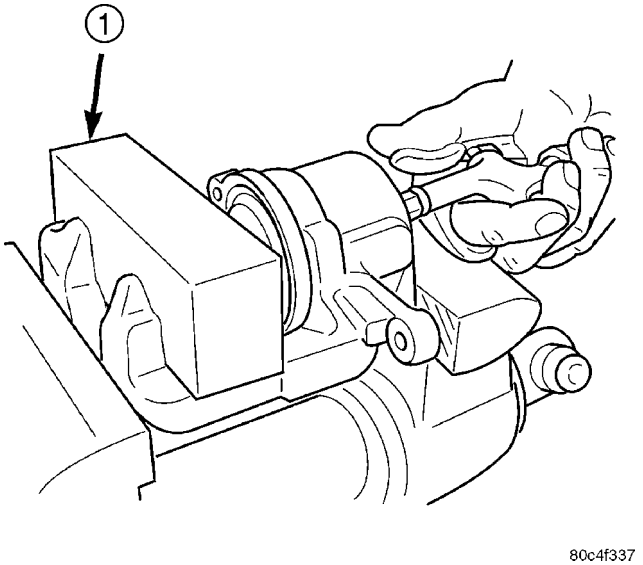

Fig. 37 Piston Removal

1 - WOOD BLOCK

WARNING: DO NOT PLACE FACE OR HANDS NEAR CALIPER AND PISTON IF USING COMPRESSED AIR PRESSURE TO REMOVE PISTON. DO NOT USE HIGH PRESSURE.

DISC BRAKE CALIPER - FRONT (Continued)

(3) If necessary, apply low pressure compressed air to the caliper fluid inlet in short spurts to force the piston out.

(4) Remove the piston from the caliper.

(5) Remove the dust boot from the piston and discard it.

CAUTION: Do not use a screw driver or other metal tool for seal removal. Using such tools can scratch the bore or leave burrs on the seal groove edges.

(6) Using a soft tool such as a plastic trim stick, work the piston seal out of its groove in caliper piston bore (Fig. 38). Discard the old seal.

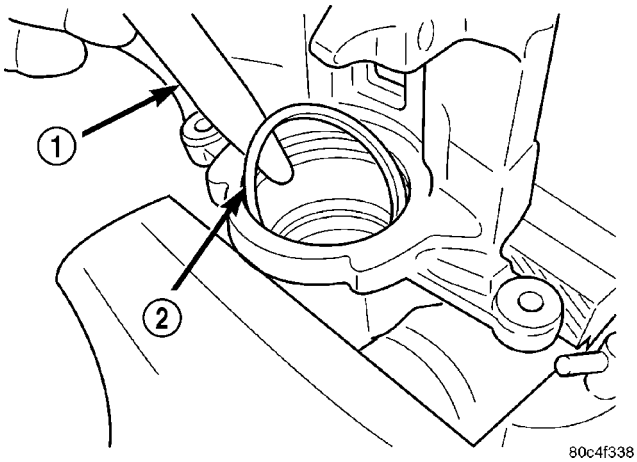

Fig. 38 Piston Seal Removal

1 - TRIM STICK
2 - SEAL

(7) Clean the piston bore and drilled passage ways with alcohol or a suitable solvent. Wipe it dry using only a lint-free cloth.

(8) Inspect both the piston and bore for scoring or pitting. Bores that show light scratches or corrosion can usually be cleared of the light scratches or corrosion using crocus cloth.

CLEANING - DISC BRAKE CALIPER

WARNING: DUST AND DIRT ACCUMULATING ON BRAKE PARTS DURING NORMAL USE MAY CONTAIN ASBESTOS FIBERS FROM PRODUCTION OR AFTERMARKET BRAKE LININGS. BREATHING EXCESSIVE CONCENTRATIONS OF ASBESTOS FIBERS CAN CAUSE SERIOUS BODILY HARM. EXERCISE CARE WHEN SERVICING BRAKE PARTS. DO NOT SAND OR GRIND BRAKE LINING UNLESS EQUIPMENT USED IS DESIGNED TO CONTAIN THE DUST RESIDUE. DO NOT CLEAN BRAKE PARTS WITH COMPRESSED AIR OR BY DRY BRUSHING. CLEANING SHOULD BE DONE BY DAMPENING THE BRAKE COMPONENTS WITH A FINE MIST OF WATER, THEN WIPING THE BRAKE COMPONENTS CLEAN WITH A DAMPENED CLOTH. DISPOSE OF CLOTH AND ALL RESIDUE CONTAINING ASBESTOS FIBERS IN AN IMPERMEABLE CONTAINER WITH THE APPROPRIATE LABEL. FOLLOW PRACTICES PRESCRIBED BY THE OCCUPATIONAL SAFETY AND HEALTH ADMINISTRATION (OSHA) AND THE ENVIRONMENTAL PROTECTION AGENCY (EPA) FOR THE HANDLING, PROCESSING, AND DISPOSING OF DUST OR DEBRIS THAT MAY CONTAIN ASBESTOS FIBERS.

To clean or flush the internal passages of the brake caliper, use fresh brake fluid or Mopar® Non-Chlorinated Brake Parts Cleaner. Never use gasoline, kerosene, alcohol, oil, transmission fluid or any fluid containing mineral oil to clean the caliper. These fluids will damage rubber cups and seals.

INSPECTION - DISC BRAKE CALIPER

Inspect the disc brake caliper for the following:

- Brake fluid leaks in and around piston boot area
- Ruptures, brittleness or damage to the piston dust boot

If caliper fails inspection, disassemble and recondition caliper, replacing the seals and dust boots.

ASSEMBLY

NOTE: Always use new, clean brake fluid when assembling the brake caliper.

NOTE: Never use an old piston seal.

(1) Dip the new piston seal in clean brake fluid and install it in the groove of the caliper bore (Fig. 39). The seal should be started at one area of the groove and gently worked around into the groove using only your clean fingers to seat it.

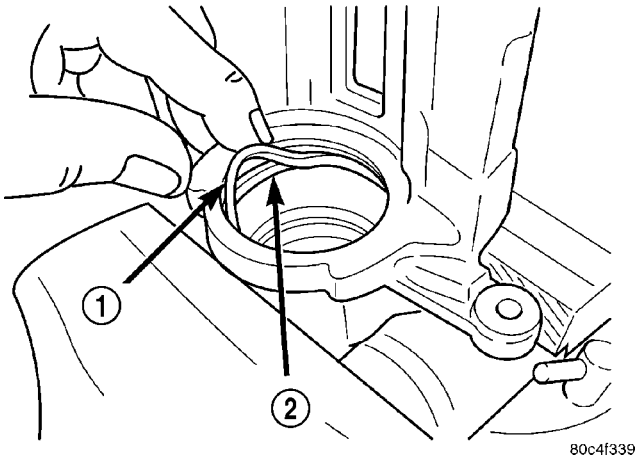

Fig. 39 New Piston Seal Installation

1 - SEAL
2 - GROOVE

DISC BRAKE CALIPER - FRONT (Continued)

(2) Coat the new piston with clean brake fluid.

(3) Coat the new piston boot with clean brake fluid leaving a generous amount inside the boot.

(4) Position the dust boot over the lower section of the piston (Fig. 40).

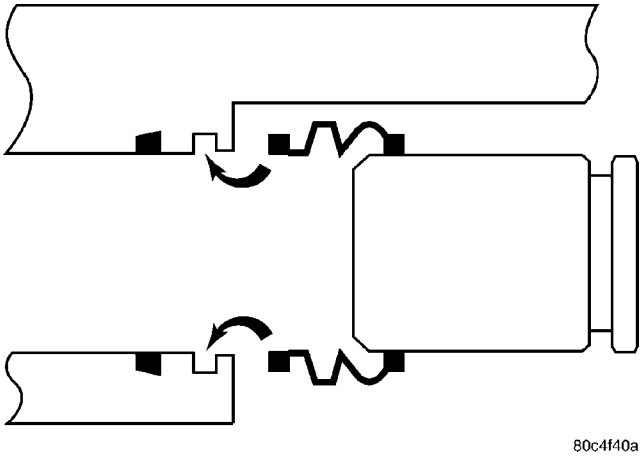

Fig. 40 Boot Installation

(5) Extend the dust boot below the bottom of the piston and guide the lip seal into the groove in the caliper piston bore.

CAUTION: Force applied to the piston to seat it in the bore must be applied uniformly to avoid cocking and binding of the piston.

(6) Install the piston into the bore carefully pushing it past the piston seal using hand pressure (Fig. 41). Push the piston in until it bottoms in the caliper bore and the dust boot lip seal falls into the groove near the top of the piston.

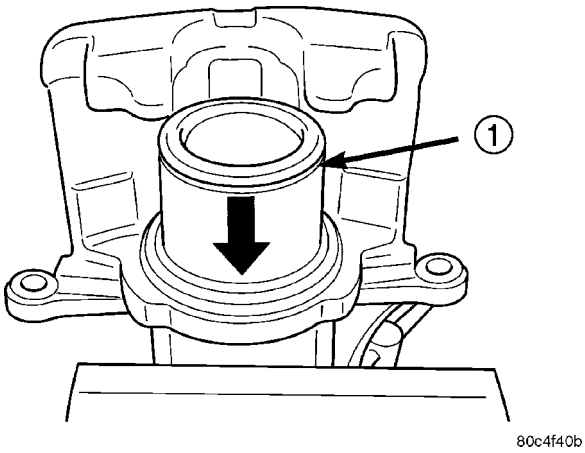

Fig. 41 Piston Installation

1 - PISTON GROOVE

(7) Reinstall the caliper on the vehicle and bleed the brakes as necessary. (Refer to 5 - BRAKES/HYDRAULIC/MECHANICAL/DISC BRAKE CALIPER - INSTALLATION)

INSTALLATION

CAUTION: When installing new brake components, be sure to use correct parts. Parts designed for BR4 Performance Brake System must not be mixed with other brake systems. These parts, similar in appearance, can be easily identified (Fig. 13) (Fig. 14). (Refer to 5 - BRAKES/HYDRAULIC/MECHANICAL - DESCRIPTION - DISC BRAKES (FRONT))

(1) Completely retract the caliper piston back into the bore of the caliper. Use a C-clamp to retract the piston. Place a wood block over the piston before installing the C-clamp to avoid damaging the piston.

CAUTION: Use care when installing the caliper onto the disc brake adapter to avoid damaging the boots on the caliper guide pins.

(2) Install the disc brake caliper over the brake shoes on the brake caliper adapter. Make sure the springs on the shoes do not get caught in the hole formed into the center of the caliper housing.

(3) Align the caliper guide pin bolt holes with the guide pins. Install the caliper guide pin bolts and tighten them to a torque of 35 N·m (26 ft. lbs.) (Fig. 36).

(4) Install the banjo bolt connecting the brake hose to the brake caliper (Fig. 36). Install NEW washers on each side of the hose fitting as the banjo bolt is guided through the fitting. Thread the banjo bolt into the caliper and tighten it to a torque of 24 N·m (210 in. lbs.).

(5) Install the tire and wheel assembly. Tighten the wheel mounting nuts to a torque of 135 N·m (100 ft. lbs.).

(6) Lower the vehicle.

(7) Remove the brake pedal holding tool.

(8) Bleed the caliper as necessary. (Refer to 5 - BRAKES - STANDARD PROCEDURE)

(9) Road test the vehicle and make several stops to wear off any foreign material on the brakes and to seat the brake shoes.

DISC BRAKE CALIPER - REAR

REMOVAL

NOTE: Before proceeding, (Refer to 5 - BRAKES - WARNING) (Refer to 5 - BRAKES - CAUTION).

(1) Using a brake pedal holding tool as shown (Fig. 42), depress the brake pedal past its first one inch of travel and hold it in this position. This will isolate the master cylinder from the brake hydraulic system and will not allow the brake fluid to drain out of the master cylinder reservoir while the lines are disconnected.

DISC BRAKE CALIPER - REAR (Continued)

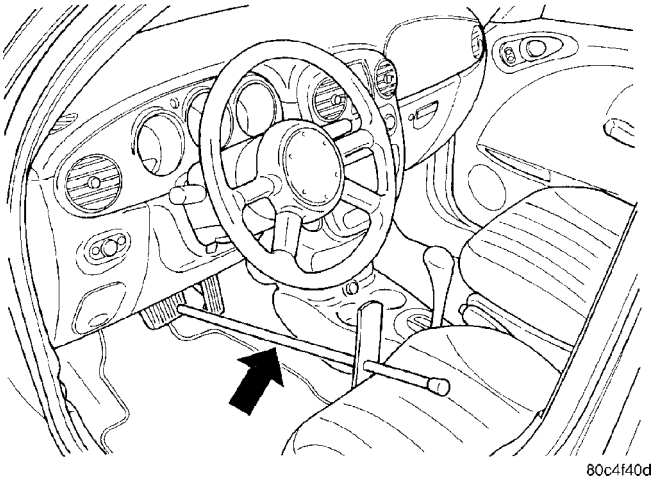

Fig. 42 Brake Pedal Holding Tool

(2) Raise the vehicle. (Refer to LUBRICATION & MAINTENANCE/HOISTING - STANDARD PROCEDURE)

(3) Remove the rear tire and wheel assembly.

(4) Remove the banjo bolt connecting the brake hose to the brake caliper (Fig. 43). There are two washers (one on each side of the flex hose fitting) that will come off with the banjo bolt. Discard the washers.

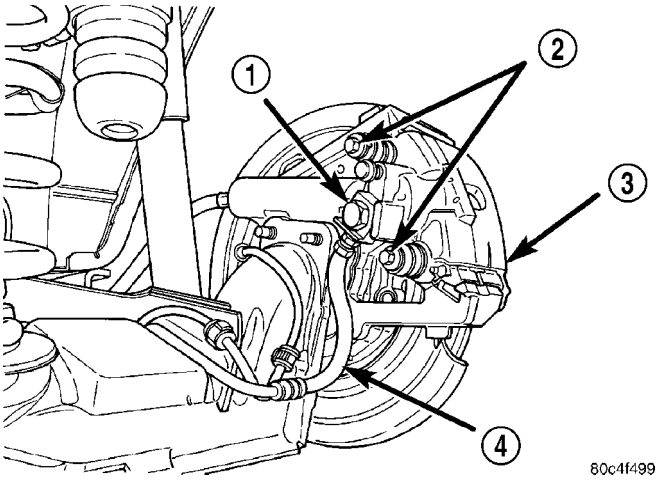

Fig. 43 Brake Hose Mounting

1 - BANJO BOLT
2 - GUIDE PIN BOLTS
3 - CALIPER
4 - BRAKE HOSE

NOTE: In some cases, it may be necessary to retract the caliper piston in its bore a small amount in order to provide sufficient clearance between the shoes and the rotor to easily remove the caliper from the knuckle. This can usually be accomplished before the guide pin bolts are removed, by grasping the rear of the caliper and pulling outward working with the guide pins, thus retracting the piston. Never push on the piston directly as it may get damaged.

(5) Remove the two caliper guide pin bolts (Fig. 44).

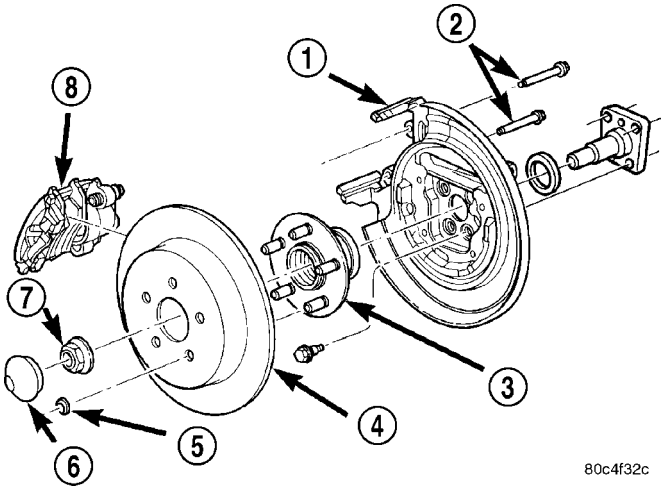

Fig. 44 Caliper Mounting

1 - DISC BRAKE ADAPTER
2 - GUIDE PIN BOLTS
3 - HUB AND BEARING
4 - BRAKE ROTOR
5 - RETAINER CLIP
6 - DUST CAP
7 - NUT
8 - DISC BRAKE CALIPER

(6) Remove the caliper assembly from the brake adapter by first rotating the top of the caliper away from the rotor, and then lifting the caliper assembly off the machined abutment on the adapter (Fig. 45).

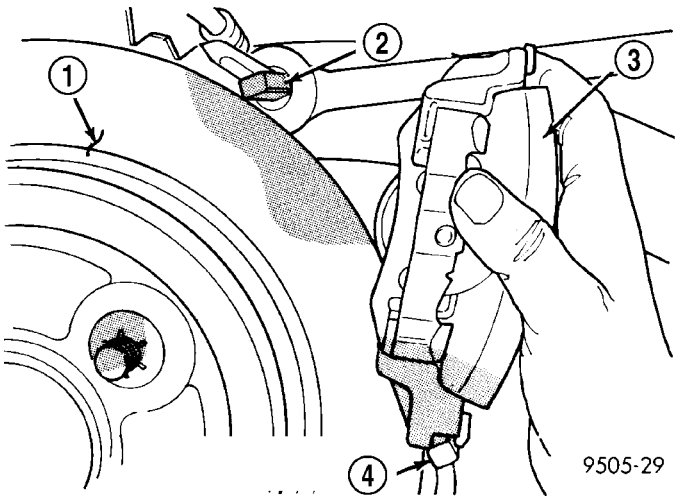

Fig. 45 Removing Caliper From Adapter

1 - BRAKING DISC
2 - CALIPER ADAPTER
3 - CALIPER
4 - LOWER MACHINED ADAPTER ABUTMENT

DISC BRAKE CALIPER - REAR (Continued)

DISASSEMBLY

DISASSEMBLY - DISC BRAKE CALIPER (GUIDE PIN BUSHINGS)

Before disassembling the brake caliper, clean and inspect it. (Refer to 5 - BRAKES/HYDRAULIC/MECHANICAL/DISC BRAKE CALIPERS - INSPECTION).

(1) With one hand, push the guide pin bushing sleeve towards the back of the caliper, and at the same time, pull the sleeve out the back of the caliper and bushing (Fig. 46).

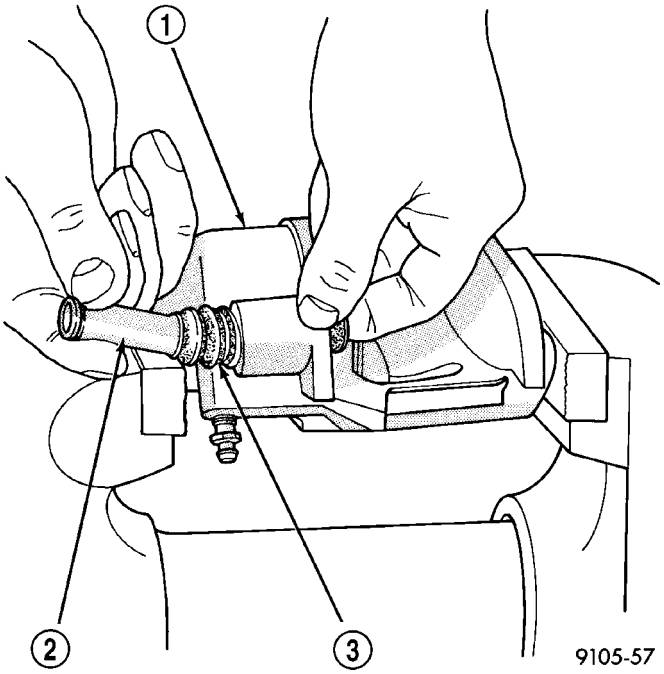

Fig. 46 Removing Sleeve From Bushing

1 - CALIPER
2 - SLEEVE
3 - BUSHING

(2) Using your fingers, collapse one side of the rubber guide pin bushing. Pull the guide pin bushing out the other side of the brake caliper mounting boss (Fig. 47).

DISASSEMBLY - DISC BRAKE CALIPER (PISTON AND SEAL)

Before disassembling the brake caliper, clean and inspect it. (Refer to 5 - BRAKES/HYDRAULIC/MECHANICAL/DISC BRAKE CALIPERS - INSPECTION).

CALIPER PISTON REMOVAL

WARNING: UNDER NO CONDITION SHOULD HIGH PRESSURE AIR EVER BE USED TO REMOVE A PISTON FROM A CALIPER BORE. PERSONAL INJURY COULD RESULT FROM SUCH A PRACTICE.

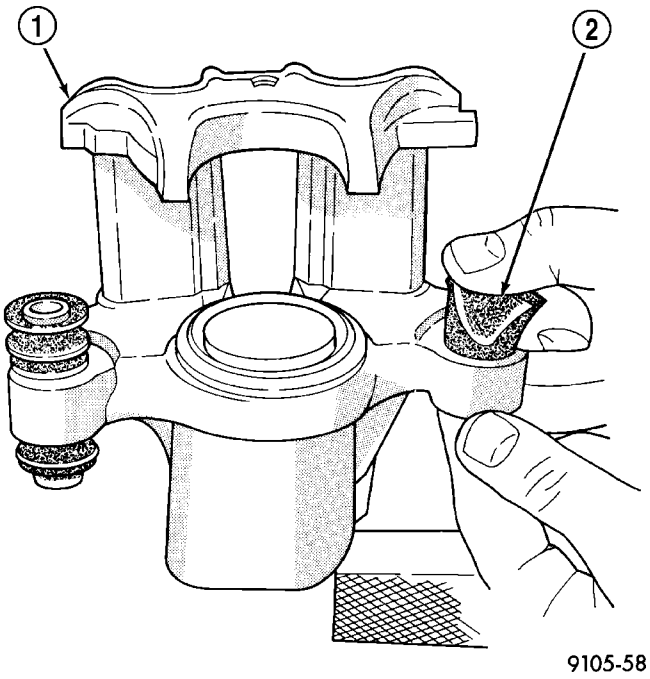

Fig. 47 Removing Bushing From Caliper

1 - CALIPER
2 - BUSHING

NOTE: The safest way to remove the piston from the caliper bore is to use the hydraulic pressure of the vehicle's brake system.

(1) Following the removal procedure in DISC BRAKE SHOES (Refer to 5 - BRAKES/HYDRAULIC/MECHANICAL/BRAKE PADS/SHOES - REMOVAL), remove the caliper from the brake rotor and hang the assembly on a wire hook away from rotor and body of the vehicle so brake fluid cannot get on these components. Remove the brake shoes, and place a small piece of wood between the piston and caliper fingers.

(2) Carefully depress the brake pedal to hydraulically push piston out of its bore. Once completed, apply and hold down the brake pedal to any position beyond the first inch of pedal travel using a brake pedal holding tool. This will prevent the fluid in the master cylinder reservoir from completely draining out.

(3) Disconnect the brake fluid flex hose from the caliper assembly and remove it from the vehicle.

CALIPER SEAL REMOVAL

CAUTION: Do not use excessive force when clamping caliper in vise. Excessive vise pressure will cause bore distortion.

DISC BRAKE CALIPER - REAR (Continued)

(1) To disassemble the caliper, mount it in a vise equipped with protective jaws.

(2) Remove the piston dust boot from the caliper and discard (Fig. 48).

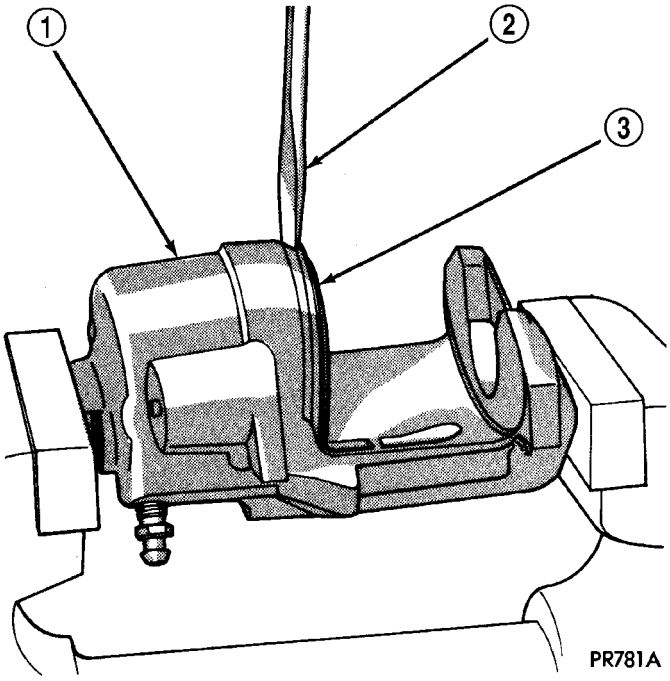

Fig. 48 Removing Caliper/Piston Dust Boot

1 - CALIPER
2 - SCREWDRIVER
3 - BOOT

NOTE: Do not use a screw driver or other metal tool for seal removal. Using such tools can scratch the bore or leave burrs on the seal groove edges.

(3) Using a soft tool such as a plastic trim stick, work the piston seal out of its groove in caliper piston bore (Fig. 49). Discard the old seal.

(4) Clean the piston bore and drilled passage ways using alcohol or a suitable solvent. Wipe it dry using only a lint-free cloth.

(5) Inspect the piston bore for scoring or pitting. Bores that show light scratches or corrosion can usually be cleared of the light scratches or corrosion using crocus cloth. Bores that have deep scratches or scoring should be honed. Use Caliper Hone, Special Tool C-4095, or the equivalent to hone the bore. Do not over-hone the bore. Don not increase the diameter of the bore more than 0.0254 mm (0.001 inch) (Fig. 50). If the bore does not clean up within this specification, a new caliper housing should be installed.

NOTE: During the honing procedure, coat the stones and bore with brake fluid. After honing the bore, carefully clean the seal and boot grooves with a stiff non-metallic rotary brush. Use extreme care in cleaning the caliper after honing. Remove all dirt and grit by flushing the caliper bore with fresh clean brake fluid; wipe it dry with a clean, lint free cloth and then clean it a second time.

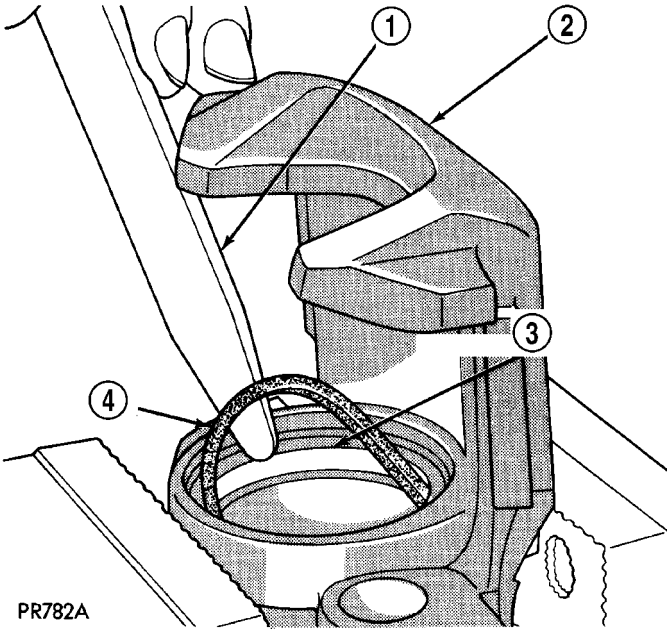

Fig. 49 Removing Piston Seal

1 - PLASTIC TRIM STICK

4 - PISTON SEAL

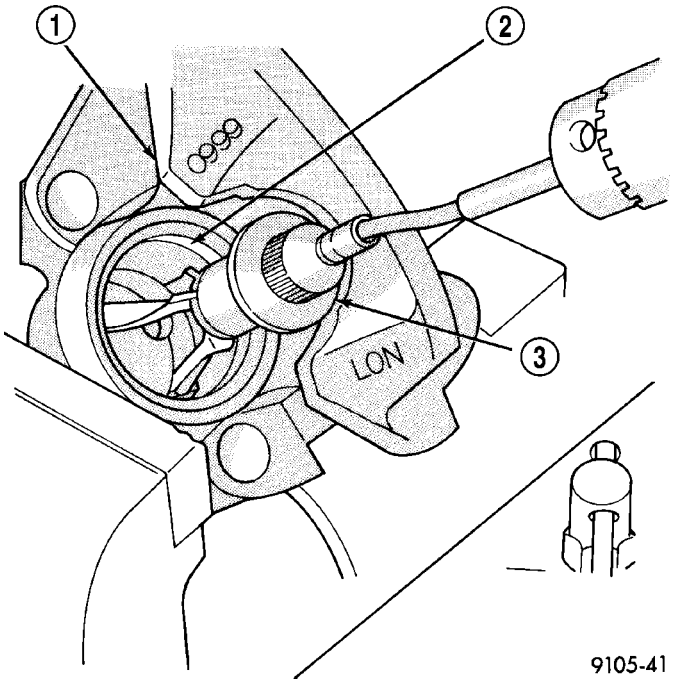

Fig. 50 Honing Brake Caliper Piston Bore

1 - CALIPER
2 - CALIPER BORE
3 - SPECIAL TOOL C-4095

DISC BRAKE CALIPER - REAR (Continued)

(6) Inspect the caliper piston for pitting, scratches, or any physical damage. Replace the piston if there is evidence of scratches, pitting or physical damage.

CLEANING - DISC BRAKE CALIPER

WARNING: DUST AND DIRT ACCUMULATING ON BRAKE PARTS DURING NORMAL USE MAY CONTAIN ASBESTOS FIBERS FROM PRODUCTION OR AFTERMARKET BRAKE LININGS. BREATHING EXCESSIVE CONCENTRATIONS OF ASBESTOS FIBERS CAN CAUSE SERIOUS BODILY HARM. EXERCISE CARE WHEN SERVICING BRAKE PARTS. DO NOT SAND OR GRIND BRAKE LINING UNLESS EQUIPMENT USED IS DESIGNED TO CONTAIN THE DUST RESIDUE. DO NOT CLEAN BRAKE PARTS WITH COMPRESSED AIR OR BY DRY BRUSHING. CLEANING SHOULD BE DONE BY DAMPENING THE BRAKE COMPONENTS WITH A FINE MIST OF WATER, THEN WIPING THE BRAKE COMPONENTS CLEAN WITH A DAMPENED CLOTH. DISPOSE OF CLOTH AND ALL RESIDUE CONTAINING ASBESTOS FIBERS IN AN IMPERMEABLE CONTAINER WITH THE APPROPRIATE LABEL. FOLLOW PRACTICES PRESCRIBED BY THE OCCUPATIONAL SAFETY AND HEALTH ADMINISTRATION (OSHA) AND THE ENVIRONMENTAL PROTECTION AGENCY (EPA) FOR THE HANDLING, PROCESSING, AND DISPOSING OF DUST OR DEBRIS THAT MAY CONTAIN ASBESTOS FIBERS.

To clean or flush the internal passages of the brake caliper, use fresh brake fluid or Mopar® Non-Chlorinated Brake Parts Cleaner. Never use gasoline, kerosene, alcohol, oil, transmission fluid or any fluid containing mineral oil to clean the caliper. These fluids will damage rubber cups and seals.

INSPECTION - DISC BRAKE CALIPER

Inspect the disc brake caliper for the following:

- Brake fluid leaks in and around boot area and inboard lining
- Ruptures, brittleness or damage to the piston dust boot
- Damaged, dry or brittle guide pin dust boots

If caliper fails inspection, disassemble and recondition caliper, replacing the seals and dust boots.

ASSEMBLY

ASSEMBLY - DISC BRAKE CALIPER (GUIDE PIN BUSHINGS)

(1) Fold the guide pin bushing in half lengthwise at the solid middle section (Fig. 51).

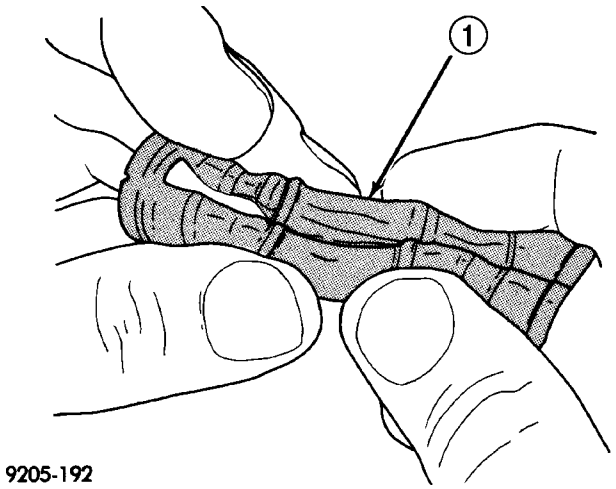

Fig. 51 Folded Caliper Guide Pin Bushing

1 - CALIPER GUIDE PIN BUSHING

NOTE: To avoid damage to the bushing, do not use a sharp object to install the guide pin bushing.

(2) Insert the folded bushing into the caliper mounting boss using your fingers (Fig. 52).

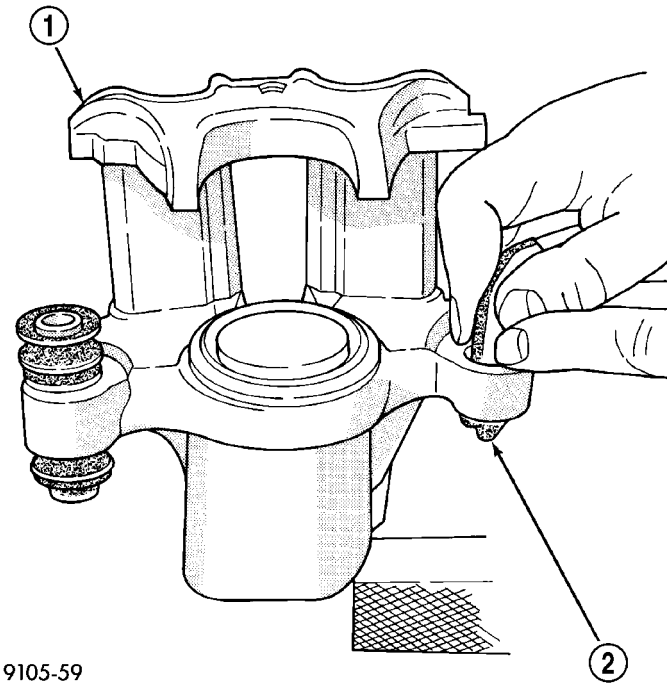

Fig. 52 Installing Caliper Guide Pin Bushing

1 - CALIPER
2 - BUSHING

(3) Unfold the bushing using your fingers or a wooden dowel until the bushing is fully seated into the caliper housing. The bushing flanges should be seated evenly on both sides of the bushing hole (Fig. 53).

DISC BRAKE CALIPER - REAR (Continued)

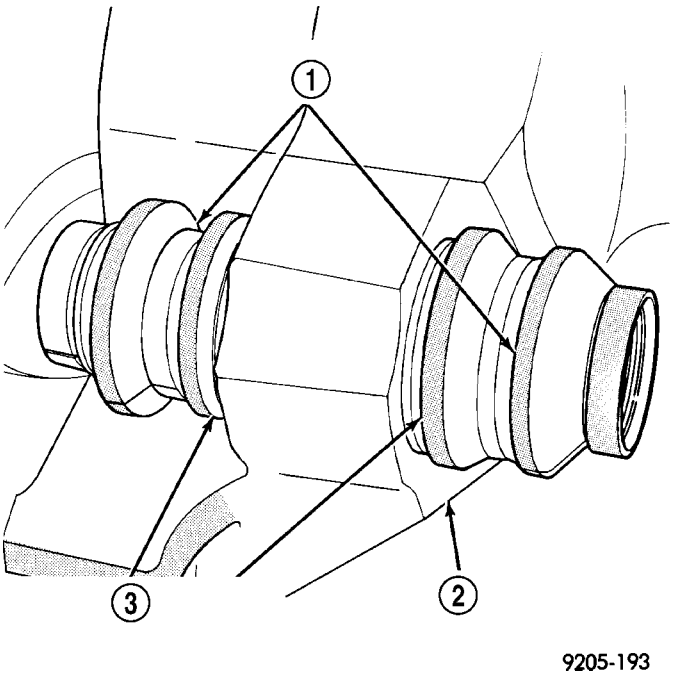

Fig. 53 Bushing Correctly Installed In Caliper

1 - BUSHING
2 - CALIPER
3 - BE SURE BOTH BUSHING FLANGES ARE FULLY SEATED AROUND CALIPER BUSHING BORES.

(4) Lubricate the inside surfaces of the bushing using Mopar Dielectric Grease or an equivalent.

(5) Install the guide pin sleeve into one end of bushing until the seal area of bushing is past the seal groove in the sleeve (Fig. 54).

(6) Holding the convoluted boot on the opposite end of the bushing, push the steel sleeve through the bushing until the bushing boot is fully seated into the seal groove on that end of sleeve (Fig. 54). Install the other end bushing boot into the groove on that end of the bushing sleeve.

(7) Verify both ends of the bushing are seated in the sleeve groves (Fig. 55). When the sleeve is seated properly into the bushing, the sleeve/bushing can be held between your fingers and easily slid back and forth without the bushing unseating from the sleeve groove.

ASSEMBLY - DISC BRAKE CALIPER (PISTON AND SEAL)

NOTE: Never use an old piston seal.

(1) Dip the new piston seal in clean brake fluid and install it in the groove of the caliper bore. The seal should be started at one area of the groove and gently worked around and into the groove (Fig. 56) using only your clean fingers to seat it.

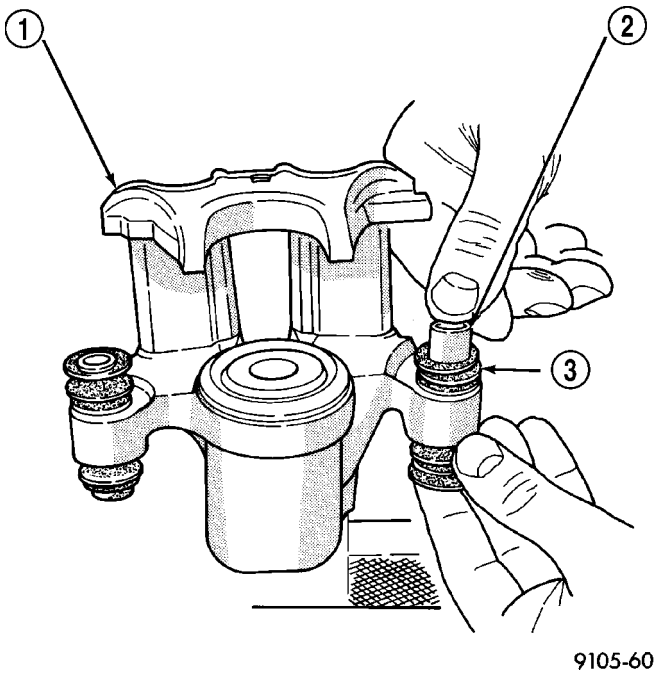

Fig. 54 Installing Sleeve In Bushing

1 - CALIPER
2 - SLEEVE
3 - BUSHING

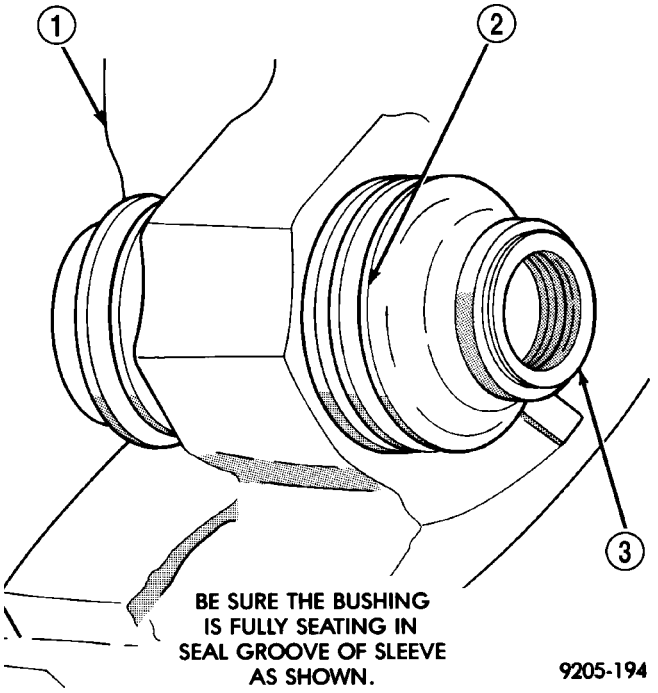

Fig. 55 Correctly Installed Guide Pin Sleeve And Bushing

1 - CALIPER
2 - BUSHING
3 - SLEEVE

(2) Coat the new piston boot with clean brake fluid leaving a generous amount inside the boot.

DISC BRAKE CALIPER - REAR (Continued)

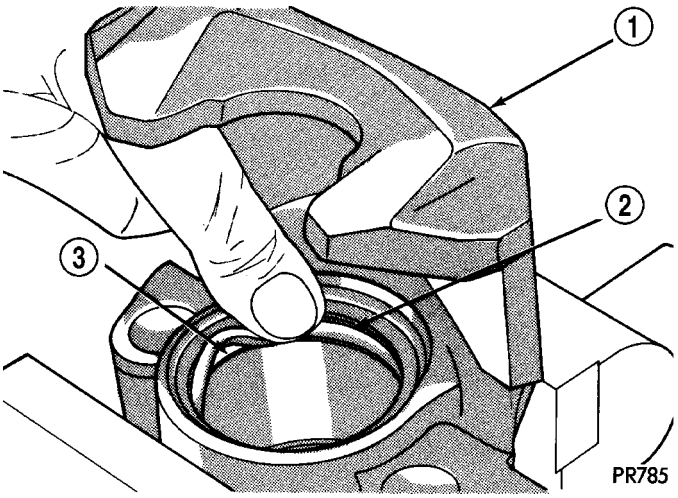

Fig. 56 Installing New Piston Seal

1 - CALIPER
2 - PISTON SEAL
3 - SEAL GROOVE

(3) Position the dust boot over the piston after coating it with brake fluid.

CAUTION: Force applied to the piston to seat it in the bore must be applied uniformly to avoid cocking and binding of the piston.

(4) Install piston into caliper bore pushing it past the piston seal until it bottoms in the caliper bore (Fig. 57).

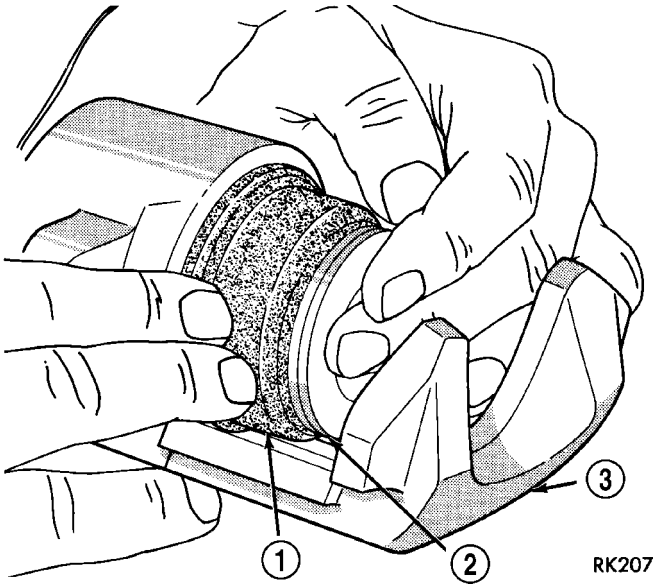

Fig. 57 Installing Piston Into Caliper Bore

1 - BOOT
2 - PISTON
3 - CALIPER

(5) Position the dust boot into the counterbore of the caliper assembly piston bore.

(6) Using a hammer and Installer, Special Tool C-4689, and Handle, Special Tool C-4171, drive the boot into the counterbore of the caliper (Fig. 58).

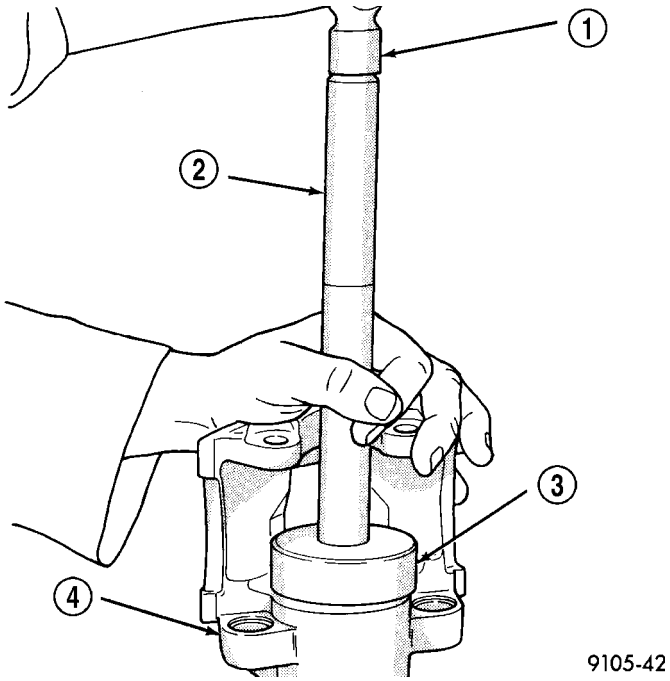

Fig. 58 Installing Dust Boot In Caliper Counterbore

1 - HAMMER
2 - SPECIAL TOOL C-4171
3 - SPECIAL TOOL C-4689
4 - CALIPER

(7) Install the brake shoes (Refer to 5 - BRAKES/HYDRAULIC/MECHANICAL/BRAKE PADS/SHOES - INSTALLATION).

(8) Reinstall the caliper on the vehicle and bleed the brakes as necessary. (Refer to 5 - BRAKES/HYDRAULIC/MECHANICAL/DISC BRAKE CALIPERS - INSTALLATION).

INSTALLATION

CAUTION: When installing new brake components, be sure to use correct parts. Parts designed for BR4 Performance Brake System must not be mixed with other brake systems. These parts, similar in appearance, can be easily identified (Fig. 16) (Fig. 17). (Refer to 5 - BRAKES/HYDRAULIC/MECHANICAL - DESCRIPTION - DISC BRAKES (REAR))

NOTE: Step (1) below is only required when installing the disc brake caliper after new brake shoes have been installed.

(1) Completely retract the caliper piston back into piston bore of the caliper.

DISC BRAKE CALIPER - REAR (Continued)

(2) Lubricate both adapter caliper slide abutments with a liberal amount of Mopar® Multipurpose Lubricant, or an equivalent.

CAUTION: Use care when installing the caliper assembly onto adapter so the guide pin bushings and sleeves do not get damaged by the mounting bosses on adapter.

(3) Starting with the lower end, carefully lower the caliper and brake shoes over the brake rotor and catch the caliper's bottom edge behind the caliper slide abutment (Fig. 45). Rotate the top of the caliper into mounting position on the adapter.

CAUTION: Extreme caution should be taken not to cross thread the caliper guide pin bolts when they are installed.

(4) Carefully install the caliper guide pin bolts (Fig. 44), then tighten them to a torque of 22 N·m (192 in. lbs.).

(5) Install the banjo bolt connecting the brake hose to the brake caliper (Fig. 43). Install NEW washers. Place one fitting washer on each side of the hose fitting as the banjo bolt is guided through the fitting. Thread the banjo bolt into the caliper and tighten it to a torque of 24 N·m (210 in. lbs.).

(6) Install the tire and wheel assembly. Tighten the wheel mounting nuts to a torque of 135 N·m (100 ft. lbs.).

(7) Lower the vehicle.

(8) Remove the brake pedal holding tool.

(9) Bleed the caliper as necessary. (Refer to 5 - BRAKES - STANDARD PROCEDURE)

(10) Road test the vehicle and make several stops to wear off any foreign material on the brakes and to seat the brake shoes.

DISC BRAKE CALIPER ADAPTER - FRONT

REMOVAL

NOTE: Before proceeding, (Refer to 5 - BRAKES - WARNING) (Refer to 5 - BRAKES - CAUTION).

(1) Raise the vehicle. (Refer to LUBRICATION & MAINTENANCE/HOISTING - STANDARD PROCEDURE)

(2) Remove the front tire and wheel assembly.

(3) Remove the two brake caliper guide pin bolts (Fig. 59).

(4) Remove the disc brake caliper from the adapter. Hang the caliper out of the way using wire or a bungee cord. Use care not to overextend the brake hose when doing this.

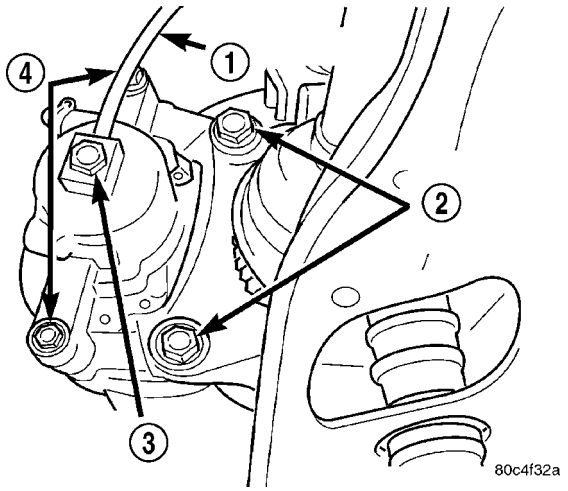

Fig. 59 Brake Caliper Mounting

1 - BRAKE HOSE
2 - ADAPTER MOUNTING BOLTS
3 - BANJO BOLT
4 - CALIPER GUIDE PIN BOLTS

(5) Remove the brake shoes from the disc brake caliper adapter (Fig. 60).

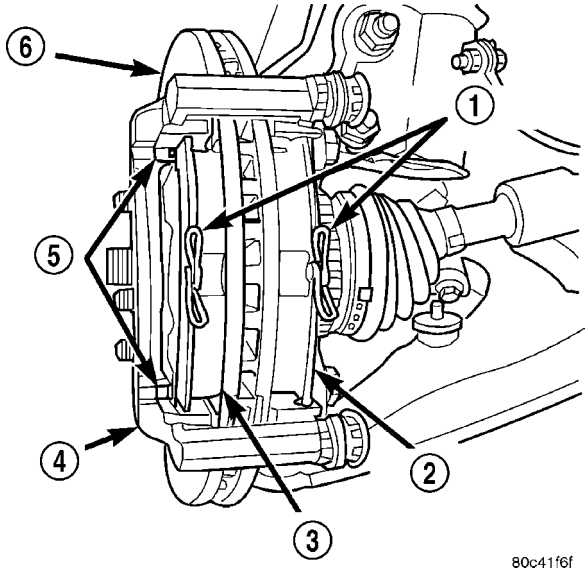

Fig. 60 Brake Shoes Mounted In Adapter

5 - ABUTMENT SHIMS
6 - BRAKE ROTOR

(6) Remove the abutment shims from the adapter (Fig. 60).

(7) Remove the two bolts securing the disc brake caliper adapter to the steering knuckle (Fig. 59).

(8) Remove the disc brake caliper adapter.

DISC BRAKE CALIPER ADAPTER - FRONT (Continued)

INSTALLATION

CAUTION: When installing new brake components, be sure to use correct parts. Parts designed for BR4 Performance Brake System must not be mixed with other brake systems. These parts, similar in appearance, can be easily identified (Fig. 13) (Fig. 14). (Refer to 5 - BRAKES/HYDRAULIC/MECHANICAL - DESCRIPTION - DISC BRAKES (FRONT))

(1) Install the disc brake caliper adapter on the steering knuckle.

(2) Install the two bolts securing the disc brake caliper adapter to the steering knuckle (Fig. 59). Tighten the bolts to a torque of 104 N·m (77 ft. lbs.).

(3) Attach the two abutment shims to the adapter fitting the contour of each shim to the adapter's contour (Fig. 60).

(4) Place the brake shoes in the abutment shims clipped into the disc brake caliper adapter as shown (Fig. 60). Place the shoe with the wear indicator attached on the inboard side.

CAUTION: Use care when installing the caliper onto the disc brake adapter to avoid damaging the boots on the caliper guide pins.

(5) Install the disc brake caliper over the brake shoes on the brake caliper adapter. Make sure the springs on the shoes do not get caught in the hole formed into the center of the caliper housing.

(6) Align the caliper guide pin bolt holes with the guide pins. Install the caliper guide pin bolts and tighten them to a torque of 35 N·m (26 ft. lbs.) (Fig. 59).

(7) Install the tire and wheel assembly. Tighten the wheel mounting nuts to a torque of 135 N·m (100 ft. lbs.).

(8) Lower the vehicle.

(9) Road test the vehicle and make several stops to wear off any foreign material on the brakes and to seat the brake shoes.

DISC BRAKE CALIPER GUIDE PINS

REMOVAL

NOTE: Before proceeding, (Refer to 5 - BRAKES - WARNING) (Refer to 5 - BRAKES - CAUTION).

(1) Raise the vehicle. (Refer to LUBRICATION & MAINTENANCE/HOISTING - STANDARD PROCEDURE)

(2) Remove the front tire and wheel assembly.

(3) Remove the two brake caliper guide pin bolts (Fig. 61).

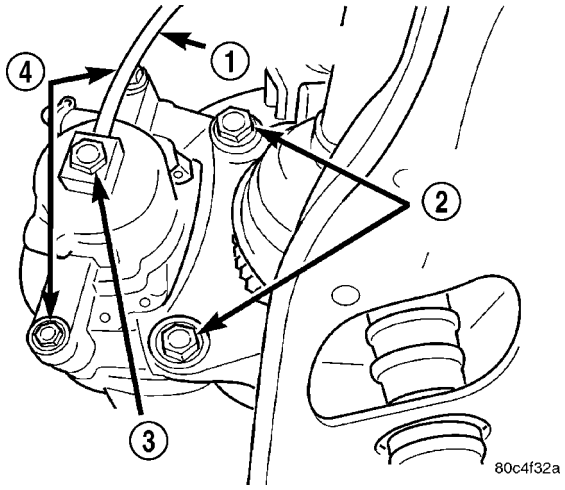

Fig. 61 Brake Caliper Mounting

1 - BRAKE HOSE
2 - ADAPTER MOUNTING BOLTS
3 - BANJO BOLT
4 - CALIPER GUIDE PIN BOLTS

(4) Remove the disc brake caliper from the disc brake caliper adapter and hang it out of the way using wire or a bungee cord. Use care not to overextend the brake hose when doing this.

(5) Remove the guide pins and boots from the adapter as shown (Fig. 62).

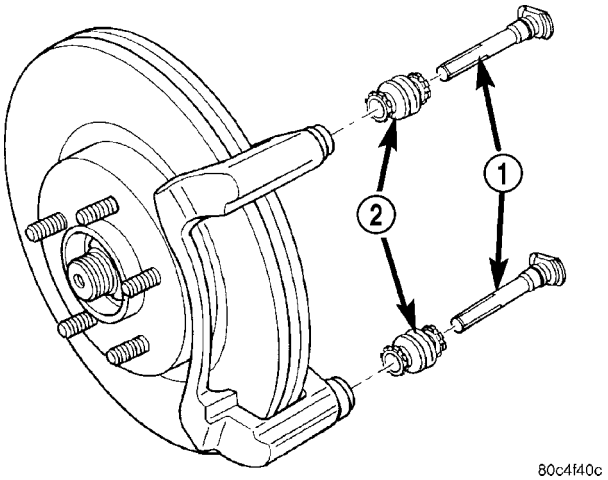

Fig. 62 Guide Pins And Boots

1 - PINS
2 - BOOTS

INSTALLATION

(1) Lubricate the guide pins and inside the boots with the packet supplied with the service kit, Sythesco GLK-1 lubricant or equivalent.

(2) Install the guide pins and boots in the adapter as shown (Fig. 62). The boots have grooves built into their inner lips to fit onto the pins and adapter.

DISC BRAKE CALIPER GUIDE PINS (Continued)

CAUTION: Use care when installing the caliper onto the disc brake adapter to avoid damaging the boots on the caliper guide pins.

(3) Install the disc brake caliper over the brake shoes on the brake caliper adapter. Make sure the springs on the shoes do not get caught in the hole formed into the center of the caliper housing.

(4) Align the caliper guide pin bolt holes with the guide pins. Install the caliper guide pin bolts and tighten them to a torque of 35 N·m (26 ft. lbs.) (Fig. 61).

(5) Install the tire and wheel assembly. Tighten the wheel mounting nuts to a torque of 135 N·m (100 ft. lbs.).

(6) Lower the vehicle.

(7) Pump the brake pedal several times before moving the vehicle to set the shoes to the brake rotor.

DRUM

DIAGNOSIS AND TESTING - BRAKE DRUM

With the drum off the vehicle, measure the drum for diameter variation (oval shape). The diameter variation of the drum braking surface must not exceed specifications listed in the following table.

Measure brake drum runout. Brake drum runout should be checked with the drum mounted on a brake lathe. Brake drum runout should not exceed specifications listed in the following table.

If either of these measurements are not within specification, reface or replace the drum. (Refer to 5 - BRAKES/HYDRAULIC/MECHANICAL/DRUM - STANDARD PROCEDURE).

Always replace the drum if machining will cause the diameter to exceed drum maximum diameter. All brake drums are marked with the maximum allowable brake drum diameter (Fig. 63). Maximum brake drum diameter can also be found in the following table.

BRAKE DRUM LIMITS

SALES CODE	DIAMETER VARIATION	RUNOUT	RUNOUT (IN 360°)	MAXIMUM DIAMETER
BRB/ BRK	0.080 mm 0.003 in.	0.045 mm in 60° 0.002 in. in 60°	0.130 mm 0.005 in.	230.60 mm 9.079 in.
Note: Vehicles without ABS are equipped with BRB drum brakes. Vehicles with ABS are equipped with BRK drum brakes.				

STANDARD PROCEDURE - BRAKE DRUM MACHINING

If a brake drum is deeply scored or warped, it can be machined on a brake lathe equipped to machine brake drums. Follow the manufacturers instructions on the machining procedure.

Measure the brake drum diameter before machining. If machining the drum will cause the drum to exceed maximum allowable diameter, do not machine the brake drum. It needs to be replaced.

CAUTION: Do not machine the brake drum if it will cause the drum to exceed maximum allowable diameter.

All brake drums are marked with the maximum allowable brake drum diameter.All vehicles have it marked on the inside of the drum (Fig. 63).

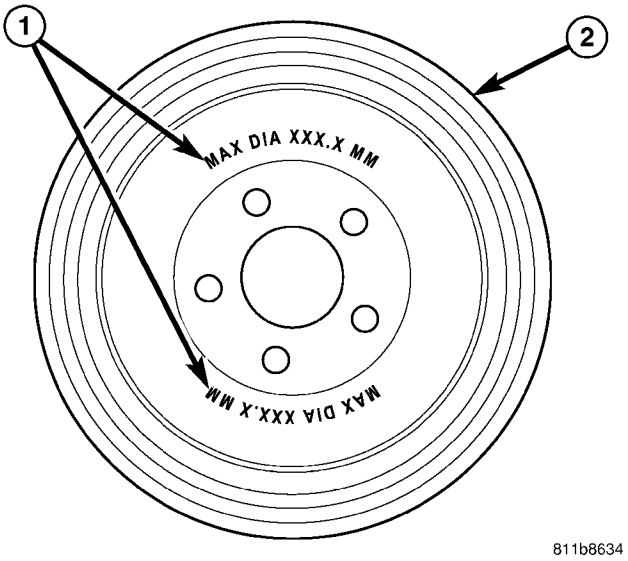

Fig. 63 Drum Maximum Diameter Identification (Inside Drum)

1 - MAXIMUM DIAMETER IDENTIFICATION MARKING
2 - BRAKE DRUM

When machining, make sure the feed rate for the final cut is set to deliver a fine finish. A fine finish helps to avoid a screw effect on the brake shoes when the brakes are applied. This final feed cut specification varies from lathe manufacturer to lathe manufacturer.

REMOVAL

NOTE: Before proceeding, (Refer to 5 - BRAKES - WARNING) (Refer to 5 - BRAKES - CAUTION).

DRUM (Continued)

(1) Raise vehicle. (Refer to LUBRICATION & MAINTENANCE/HOISTING - STANDARD PROCEDURE)

(2) Remove rear tire and wheel assembly.

(3) Remove brake drum retaining clips (if equipped) (Fig. 64).

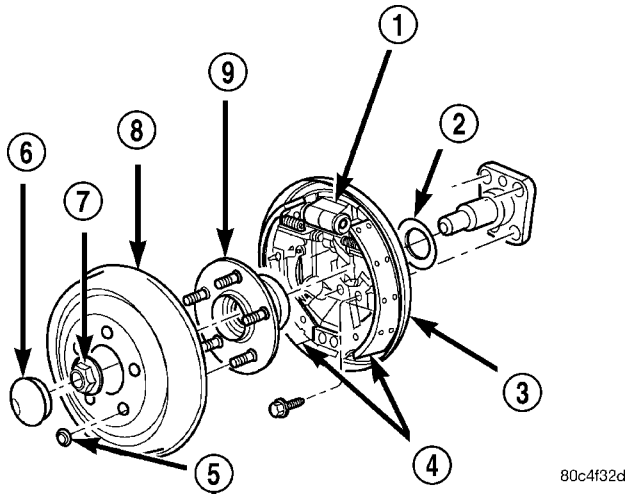

Fig. 64 Drum Brakes (Typical)

1 - WHEEL CYLINDER
2 - SEAL
3 - SUPPORT PLATE
4 - BRAKE SHOES
5 - RETAINER CLIP
6 - DUST CAP
7 - NUT
8 - DRUM
9 - HUB AND BEARING

(4) Slide brake drum off mounted wheel studs of hub and remove from vehicle (Fig. 64). If drum does not come off, further brake clearance can be obtained by removing rubber plug near top of support plate and backing off brake adjuster screw. To do so:

(a) Fabricate pawl release tool like one shown using a coat hanger or heavy mechanics wire (Fig. 65).

(b) Remove plug from rear of support plate below wheel cylinder.

(c) Insert fabricated tool through access hole in support plate, under adjuster, against lever pawl (Fig. 66). Pawl is attached to and pivots from leading shoe. When inserting tool through hole, directing tool somewhat forward (toward leading shoe) assures better contact with pawl.

(d) While pushing on pawl with fabricated tool to disengage it from adjuster star-wheel teeth (Fig. 66), rotate star-wheel downward to back off adjustment using a small screwdriver or brake adjuster tool.

(e) Once adjuster screw is backed off a sufficient amount, drum should slide off wheel studs.

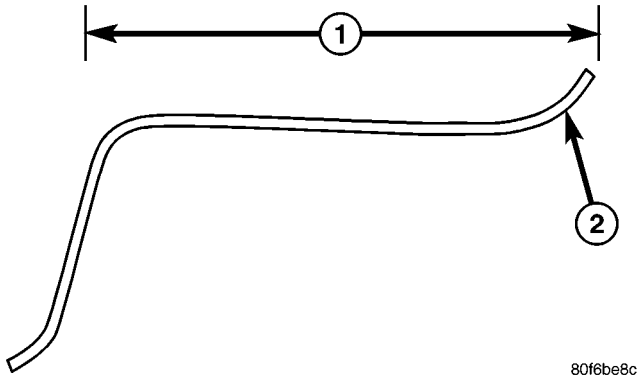

Fig. 65 Fabricated Tool

1 - APPROXIMATELY 15 CM (6 INCHES)
2 - THIS END TO BE INSERTED INTO BRAKE ASSEMBLY

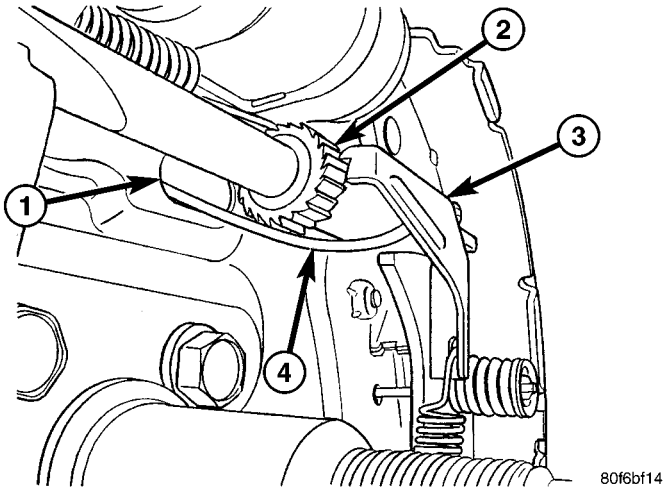

Fig. 66 Fabricated Tool Inserted Against Pawl

1 - ACCESS HOLE
2 - STAR WHEEL
3 - LEVER PAWL
4 - FABRICATED TOOL

INSTALLATION

NOTE: Before installing drum, inspect brake shoe linings for wear, alignment, and contamination. Repair or replace as necessary.

NOTE: If rust or any foreign material is present on hub, drum or wheel mating surfaces, wet wire brush these areas to remove prior to assembly of parts.

(1) Properly remove any buildup formed along outer edge of drum's machined braking surface.

(2) Adjust brake shoes to drum diameter using a brake shoe gauge. (Refer to 5 - BRAKES/HYDRAULIC/MECHANICAL/BRAKE PADS/SHOES - ADJUSTMENTS)

DRUM (Continued)

(3) Install brake drum on rear hub and bearing (Fig. 64).

(4) Install tire and wheel assembly. Tighten wheel mounting nuts to 135 N·m (100 ft. lbs.) torque.

(5) Lower vehicle.

(6) Road test vehicle stopping in both forward and reverse directions. Automatic-adjuster will continue to adjust brakes as necessary during road test.

FLUID

DIAGNOSIS AND TESTING - BRAKE FLUID CONTAMINATION

Indications of fluid contamination are swollen or deteriorated rubber parts. Swelling indicates the presence of petroleum in the brake fluid.

To test for contamination, put a small amount of drained brake fluid in clear glass jar. If the fluid separates into layers, there is mineral oil or other fluid contamination of the brake fluid.

If the brake fluid is contaminated, drain and thoroughly flush the brake system. Replace all the rubber parts or components containing rubber coming into contact with the brake fluid including: the master cylinder and reservoir; proportioning valves (non-ABS); caliper seals; wheel cylinder seals; ABS hydraulic control unit; and all hydraulic fluid hoses.

STANDARD PROCEDURE - BRAKE FLUID LEVEL CHECKING

NOTE: Brake fluid level should be checked a minimum of twice a year.

Master cylinder reservoirs are marked, FULL and ADD, indicating the allowable brake fluid level range in the master cylinder fluid reservoir (Fig. 67).

CAUTION: Use only Mopar® Brake Fluid DOT 3 Motor Vehicle or an equivalent from a tightly sealed container. Do not use petroleum-based fluid because seal damage in the brake system will result. (Refer to 5 - BRAKES/HYDRAULIC/MECHANICAL/FLUID - SPECIFICATIONS)

Although there is a range, the preferred level is FULL. As necessary, adjust the brake fluid level to the FULL mark listed on the side of the master cylinder fluid reservoir (Fig. 67). Do not overfill the system.

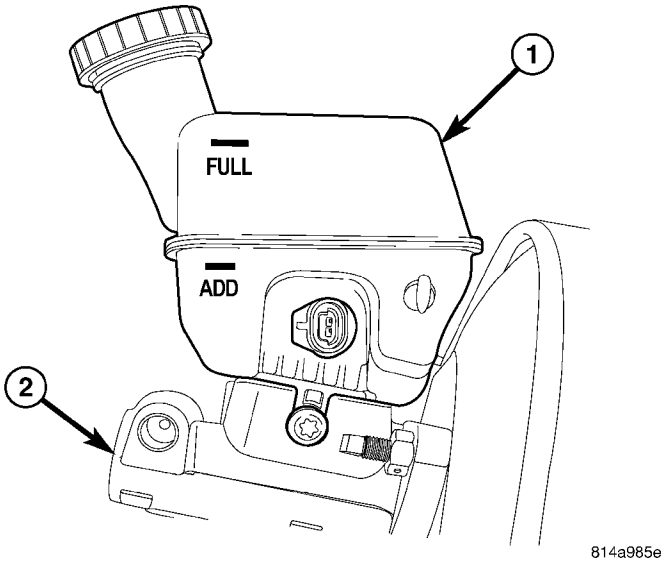

Fig. 67 Fluid Level Markings

1 - RESERVOIR
2 - MASTER CYLINDER

SPECIFICATIONS

BRAKE FLUID

The brake fluid used in this vehicle must conform to DOT 3 specifications and SAE J1703 standards. No other type of brake fluid is recommended or approved for usage in the vehicle brake system. Use only Mopar® Brake Fluid DOT 3 Motor Vehicle or an equivalent from a tightly sealed container.

CAUTION: Never use reclaimed brake fluid or fluid from an container which has been left open. An open container will absorb moisture from the air and contaminate the fluid.

CAUTION: Never use any type of a petroleum-based fluid in the brake hydraulic system. Use of such type fluids will result in seal damage of the vehicle brake hydraulic system causing a failure of the vehicle brake system. Petroleum based fluids would be items such as engine oil, transmission fluid, power steering fluid, etc.

FLUID RESERVOIR

REMOVAL - BOSCH

NOTE: The Bosch master cylinder does not need to be removed from the power brake booster for removal and installation of the brake fluid reservoir. The Continental Teves master cylinder requires removal from the power brake booster for removal and installation of the brake fluid reservoir. (Refer to 5 - BRAKES/HYDRAULIC/MECHANICAL/MASTER CYLINDER - REMOVAL) (Refer to 5 - BRAKES/HYDRAULIC/MECHANICAL/MASTER CYLINDER - DISASSEMBLY)

NOTE: Before proceeding, (Refer to 5 - BRAKES - WARNING) (Refer to 5 - BRAKES - CAUTION).

(1) Clean the master cylinder housing and brake fluid reservoir exterior surfaces.

(2) Remove the brake fluid reservoir cap. Using a clean syringe or siphoning tool, empty as much brake fluid as possible from the reservoir.

(3) Remove the vehicle wiring harness connector from brake fluid level switch in master cylinder brake fluid reservoir (Fig. 79).

(4) Remove the two plastic pins holding the reservoir to the master cylinder (Fig. 68).

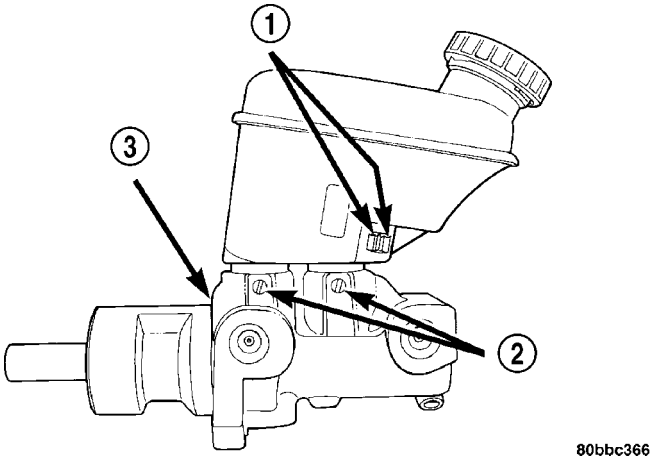

Fig. 68 Master Cylinder Reservoir

1 - BRAKE FLUID LEVEL SWITCH RETAINING TABS
2 - RESERVOIR RETAINING PINS
3 - SEAL

(5) Lift the reservoir from the master cylinder casting.

(6) Remove the grommets (O-rings) sealing the reservoir to the master cylinder housing (Fig. 69).

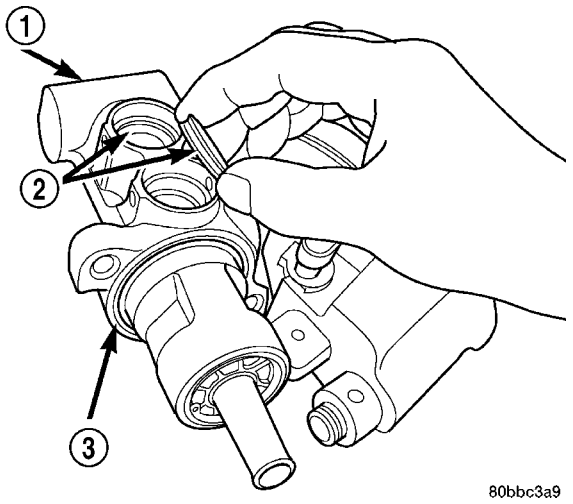

Fig. 69 Sealing Grommets

1 - MASTER CYLINDER
2 - GROMMETS (O-RINGS)
3 - SEAL

INSTALLATION - BOSCH

(1) Install NEW sealing grommets (O-rings) in the master cylinder housing (Fig. 69).

(2) Lubricate the sealing grommets with fresh clean brake fluid. Place the reservoir in position over the grommets making sure the filler hole is towards the front of the vehicle. Seat the reservoir into the grommets. While holding the reservoir firmly against the grommets, install new plastic pins through their mounting holes until they protrude out the other side of the master cylinder reservoir (Fig. 68).

(3) Connect the brake fluid level switch wiring connector (Fig. 79).

(4) Fill the reservoir with fresh clean brake fluid. (Refer to 5 - BRAKES/HYDRAULIC/MECHANICAL/FLUID - STANDARD PROCEDURE).

MASTER CYLINDER

DESCRIPTION

Two different manufacturers are used for this component. Early production PT27 (convertible) use master cylinders supplied by Bosch. Normal production vehicles (PT27 and PT44) use master cylinders supplied by Continental Teves. The master cylinder brands are not interchangeable.

The individual brands can be easily identified by the shape of the fluid reservoir. Bosch master cylinders use a more rounded reservoir while Continental Teves master cylinders use a larger, more squared-off look reservoir.

MASTER CYLINDER (Continued)

Both brand master cylinders offer two master cylinders depending on whether or not the vehicle is equipped with antilock brakes (ABS). Vehicles without ABS use a standard compensating-port master cylinder, while vehicles equipped with ABS use a center-valve design master cylinder. The bore diameter for all applications using a Bosch master cylinder is 23.82 mm (0.937 in.). The bore diameter for all applications using a Continental Teves master cylinder is 22.2 mm (0.874 in.).

All non-ABS master cylinders are a four-outlet design (one for each wheel brake). There are two ports at each piston. One feeds a front wheel brake while the other feeds the opposite side rear wheel brake. The rear wheel brake ports are drilled and threaded to accept screw-in proportioning valves (Fig. 80). One valve is threaded into the bottom of the master cylinder housing at the primary piston and the other is threaded into the right side of the master cylinder housing at the secondary piston.

All ABS master cylinders are a two-outlet design and the brake tubes from these primary and secondary outlet ports lead directly to the integrated control unit (ICU) before going to each wheel brake (Fig. 76).

All master cylinders mount to the power brake booster in the same manner.

The master cylinder body is an anodized aluminum casting. It has a machined bore to accept the master cylinder pistons and also has threaded ports with seats for hydraulic brake tube connections.

The master cylinder has the brake fluid reservoir mounted on top of it which gravity feeds brake fluid to the master cylinder when it is required. The reservoir is made of see-through plastic and it houses the brake fluid level switch. A removable brake fluid level switch is mounted in the left side.

OPERATION

When the brake pedal is pressed, the master cylinder primary and secondary pistons apply brake pressure through the proportioning valves (on non-ABS vehicles) and chassis brake tubes to each brake assembly. The brake fluid reservoir supplies the brake hydraulic system with the necessary fluid to operate properly.

The non-ABS master cylinder's primary outlet ports supply hydraulic pressure to the right front and left rear brakes while the secondary outlet ports supply hydraulic pressure to the left front and right rear brakes. ABS equipped master cylinder outlet ports supply hydraulic pressure to the ABS Integrated Control Unit (ICU) where it is distributed to the individual wheel brakes.

The master cylinder reservoir cap diaphragm is slit to allow atmospheric pressure to equalize on both sides of the diaphragm.

STANDARD PROCEDURE - MASTER CYLINDER BLEEDING

(1) Clamp the master cylinder in a vise.

NOTE: Depending on master cylinder type (Bosch or Continental Teves, with or without ABS) refer to steps 2 - 5 for proper Bleeder Tube installation.

NOTE: On vehicles without ABS this procedure is designed to be performed with the proportioning valves installed in the master cylinder.

(2) Bosch Master Cylinder without ABS – Attach four Bleeder Tubes, Special Tool 8358-1, to the four ports of the master cylinder (proportion valves installed) and tighten to 17 N·m (145 in. lbs.) torque (Fig. 70). Flex the Bleeder Tubes and position the open ends into the master cylinder reservoir so their outlets are below the surface of the brake fluid in the reservoir when filled.

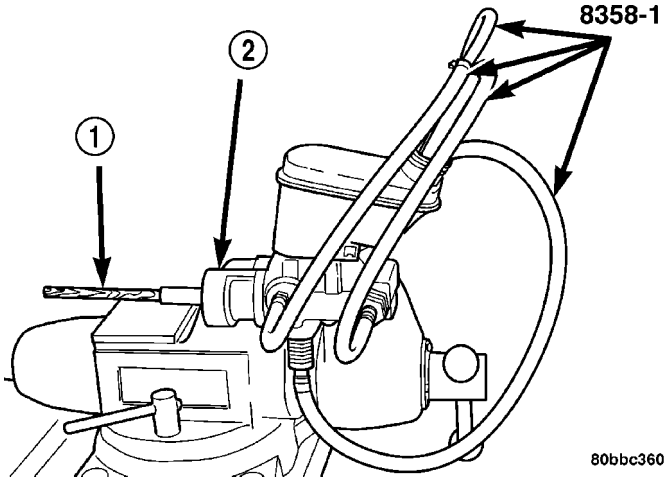

Fig. 70 Bleeding Master Cylinder - W/O ABS

1 - WOODEN DOWEL
2 - MASTER CYLINDER

(3) Bosch Master Cylinder with ABS – Attach a Bleeder Tube, Special Tool 8358-1, to the primary port of the master cylinder and tighten to 17 N·m (145 in. lbs.) torque (Fig. 71). Attach a Bleeder Tube, Special Tool 8358-2, to the secondary port of the master cylinder and tighten to 17 N·m (145 in. lbs.) torque. Flex the Bleeder Tubes and position the open ends of the tubes into the master cylinder reservoir so their outlets are below the surface of the brake fluid in the reservoir when filled.

MASTER CYLINDER (Continued)

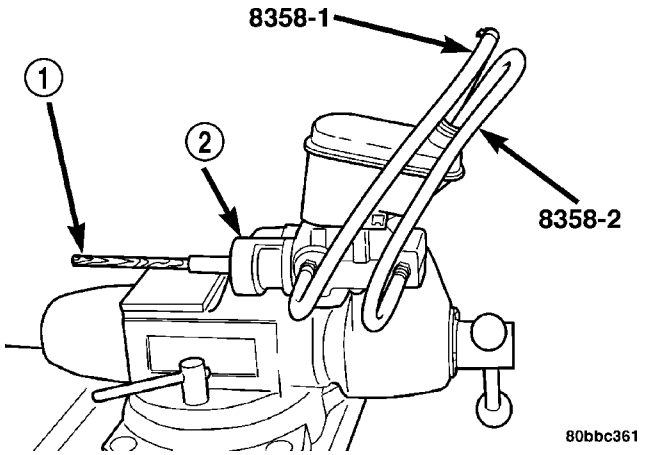

Fig. 71 Bleeding Master Cylinder - W/ABS

1 - WOODEN DOWEL
2 - MASTER CYLINDER

NOTE: Continental Teves Master Cylinder without ABS – In the following step the last substep states to submerge the ends of the Bleeder Tubes in a jar filled with brake fluid instead of the master cylinder reservoir. That is because all four Bleeder Tubes will not fit through the slot at the base of the reservoir neck (Fig. 72), sufficiently below the fluid level.

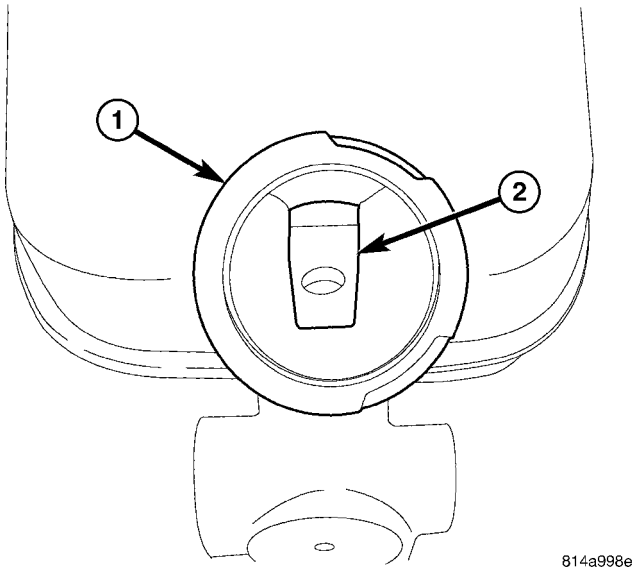

Fig. 72 Master Cylinder Reservoir Neck

1 - RESERVOIR NECK
2 - SLOT

(4) Continental Teves Master Cylinder without ABS – Attach the special tools for bleeding the master cylinder in the following fashion (Fig. 73):

(a) Thread Adapter, Special Tool 8822-1, into the primary outlet port of the master cylinder without a proportioning valve. Tighten Adapter to 17 N·m (145 in. lbs.) torque.

(b) Thread Adapter, Special Tool 8822-2, into the secondary outlet port of the master cylinder without a proportioning valve. Tighten Adapter to 17 N·m (145 in. lbs.) torque.

(c) Thread a Bleeder Tube, Special Tool 8358-1, into each Adapter. Tighten Tube nuts to 17 N·m (145 in. lbs.) torque.

(d) Thread a Bleeder Tube, Special Tool 8358-2, into each proportioning valve. Tighten Tube nuts to 17 N·m (145 in. lbs.) torque.

(e) Flex and place the open ends of the Bleeder Tubes into a clear jar containing enough fresh brake fluid to submerge the ends on the Bleeder Tubes. Do not completely fill the jar with fluid or fluid being bled from master cylinder will overflow jar.

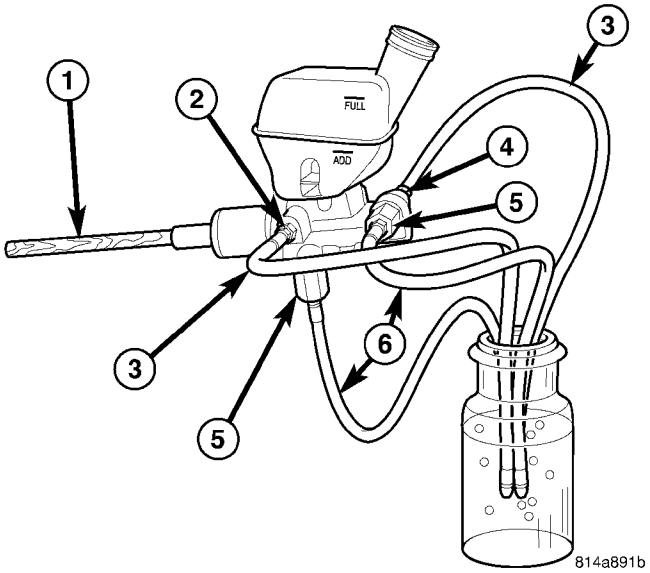

Fig. 73 Bleeding Master Cylinder - Without ABS

1 - WOODEN DOWEL
2 - ADAPTER 8822-1
3 - TUBE 8358-1
4 - ADAPTER 8822-2
5 - PROPORTIONING VALVE
6 - TUBE 8358-2

(5) Continental Teves Master Cylinder with ABS – Attach the special tools for bleeding the master cylinder in the following fashion (Fig. 74):

(a) Thread Adapter, Special Tool 8822-1, into the primary outlet port of the master cylinder. Tighten Adapter to 17 N·m (145 in. lbs.) torque.

(b) Thread Adapter, Special Tool 8822-2, into the secondary outlet port of the master cylinder. Tighten Adapter to 17 N·m (145 in. lbs.) torque.

(c) Thread a Bleeder Tube, Special Tool 8358-1, into each Adapter. Tighten Tube nuts to 17 N·m (145 in. lbs.) torque.

(d) Flex each Bleeder Tube and place open end into the neck of the master cylinder reservoir,

MASTER CYLINDER (Continued)

down through the slot at the base of the neck (Fig. 72). Position the open ends of the tubes into the reservoir so their outlets are below the surface of the brake fluid in the reservoir when filled.

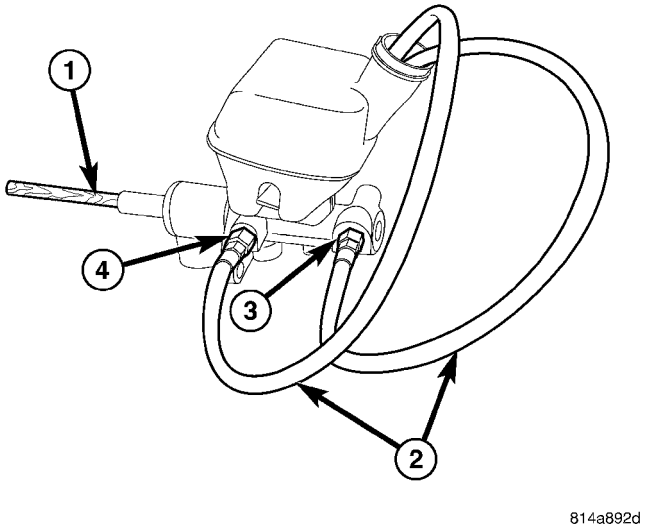

Fig. 74 Bleeding Master Cylinder - With ABS

1 - WOODEN DOWEL
2 - TUBE 8358-1
3 - ADAPTER 8822-2
4 - ADAPTER 8822-1

NOTE: Make sure ends of the Bleeder Tubes stay below the surface of the brake fluid in reservoir at all times during the bleeding procedure.

(6) Fill the brake fluid reservoir with fresh Mopar® Brake Fluid DOT 3 Motor Vehicle, or equivalent. (Refer to 5 - BRAKES/HYDRAULIC/MECHANICAL/ FLUID - SPECIFICATIONS)

(7) Using an appropriately sized wooden dowel as a pushrod (Fig. 70) (Fig. 71) (Fig. 73) (Fig. 74), slowly press the pistons inward discharging brake fluid through the Bleeder Tubes, then release the pressure, allowing the pistons to return to the released position. Repeat this several times until all air bubbles are expelled from the master cylinder bore and Bleeder Tubes.

(8) Remove the Bleed Tubes and Adapters from the master cylinder and plug the master cylinder outlet ports.

(9) Install the fill cap on the reservoir.

(10) Remove the master cylinder from the vise.

(11) Install the master cylinder on the vehicle. (Refer to 5 - BRAKES/HYDRAULIC/MECHANICAL/ MASTER CYLINDER - INSTALLATION)

REMOVAL

REMOVAL - LHD WITH ABS

NOTE: Before proceeding, (Refer to 5 - BRAKES - WARNING) (Refer to 5 - BRAKES - CAUTION).

CAUTION: The vacuum in the power brake booster must be pumped down before removing the master cylinder to prevent the booster from sucking in any contamination. This can be done by pumping the brake pedal while the engine is not running until a firm brake pedal is achieved.

(1) With the engine not running, pump the brake pedal 4-5 strokes until the pedal feel is firm.

(2) Unclip the air cleaner cover (two clips) and move the cover aside.

(3) Remove the air cleaner housing by pulling straight up.

(4) Disconnect the negative (ground) cable from the battery and isolate the cable.

(5) Unlatch the power distribution center, lift it up, and move it to the side.

(6) Remove the vehicle wiring harness connector from brake fluid level switch in master cylinder brake fluid reservoir (Fig. 75).

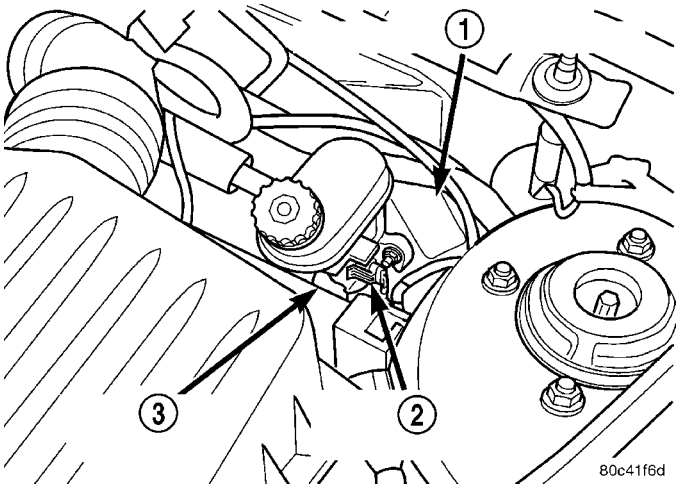

Fig. 75 Master Cylinder

(9) Slide the master cylinder straight out of the power brake booster.

DISASSEMBLY - CONTINENTAL TEVES MASTER CYLINDER

(1) Clean the master cylinder housing and brake fluid reservoir. Use only Mopar® Brake Parts Cleaner or equivalent.

(2) Remove the brake fluid reservoir cap. Using a syringe or equivalent type tool, empty as much brake fluid as possible from the reservoir.

CAUTION: When removing the fluid reservoir from the master cylinder, do not attempt to pry it off using any type of tool. This can damage the fluid reservoir or master cylinder housing.

(3) Remove the screw fastening the fluid reservoir to the master cylinder housing (Fig. 87).

(4) Pull the reservoir straight up and remove it from the grommet seals in master cylinder housing (Fig. 88).

(5) If the reservoir is being replaced, remove the fluid level switch. Push together the retaining tabs holding the brake fluid level switch in place in the brake fluid reservoir (Fig. 89), then pull the brake fluid level switch out the opposite side of the reservoir.

MASTER CYLINDER (Continued)

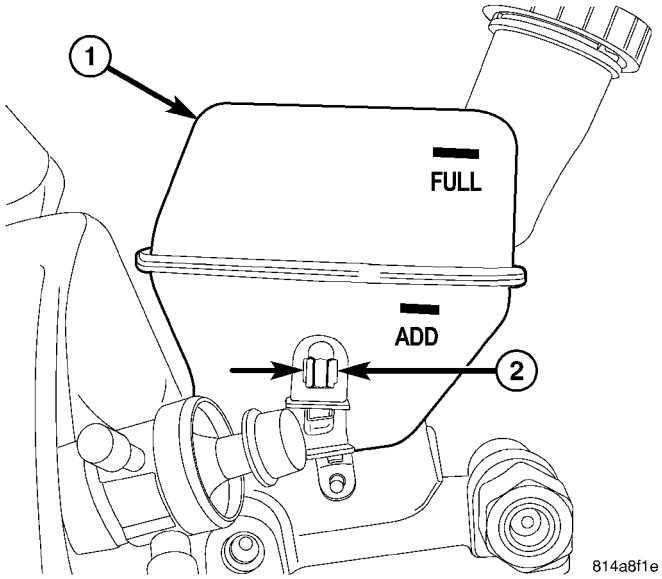

Fig. 89 Fluid Level Switch Retaining Tabs - Continental Teves

1 - RESERVOIR
2 - FLUID LEVEL SWITCH RETAINING TABS

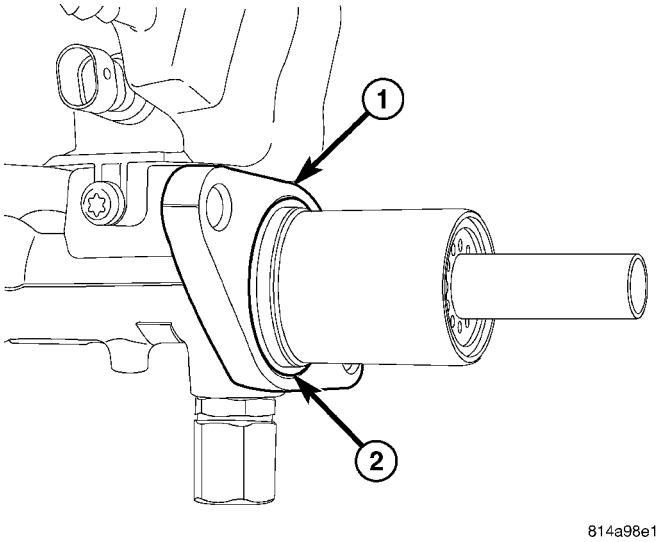

Fig. 90 Vacuum Seal On Rear Of Master Cylinder

1 - MASTER CYLINDER MOUNTING FLANGE
2 - VACUUM SEAL

ASSEMBLY - CONTINENTAL TEVES MASTER CYLINDER

(1) Install a NEW vacuum seal on the master cylinder mounting flange making sure the seal fits squarely in its groove (Fig. 90).

(2) If the reservoir is being replaced, align the brake fluid level switch with its mounting hole on the left side of the master cylinder brake fluid reservoir. Push the switch into the fluid reservoir until the switch retaining tabs are expanded on the other side of the reservoir, locking it in place (Fig. 89).

(3) Lubricate the reservoir mounting area with fresh clean brake fluid. Place the reservoir in position over the grommet seals (Fig. 88). Slide reservoir into grommet seals by firmly pressing down on fluid reservoir. Once installed, make sure fluid reservoir is touching the top of both grommet seals.

(4) Install the fluid reservoir mounting screw (Fig. 87). Tighten the screw to 4 N·m (35 in. lbs.).

(5) Thoroughly bleed master cylinder before installing it on vehicle. (Refer to 5 - BRAKES/HYDRAULIC/MECHANICAL/MASTER CYLINDER - STANDARD PROCEDURE)

(6) Install master cylinder on power brake booster. (Refer to 5 - BRAKES/HYDRAULIC/MECHANICAL/MASTER CYLINDER - INSTALLATION)

INSTALLATION

INSTALLATION - LHD WITH ABS

NOTE: The master cylinder must be bled before installing it on the vehicle.

(1) Bleed the master cylinder before installing it on the vehicle. (Refer to 5 - BRAKES/HYDRAULIC/MECHANICAL/MASTER CYLINDER - STANDARD PROCEDURE)

(2) Wipe the face of the power brake booster clean where the vacuum seal on the rear of the master cylinder comes in contact when it's installed. Do not get any cleaner or debris inside the booster.

CAUTION: When installing a master cylinder on the vehicle, a NEW vacuum seal MUST be installed on master cylinder (Fig. 91).

(3) If the master cylinder does not have a new vacuum seal installed on the mounting flange, remove it. Install a NEW vacuum seal on the master cylinder mounting flange making sure the seal fits squarely in its groove (Fig. 91).

CAUTION: If resistance is met during master cylinder insertion into power brake booster, the master cylinder push rod may not be lined up with the booster push rod. Remove the master cylinder, realign and insert it again.

(4) Line the master cylinder mounting holes up with the mounting studs on the power brake booster. Ensure the master cylinder piston push rod lines up with the booster push rod, then carefully slide the master cylinder into the power brake booster until it contacts the face of the booster.

MASTER CYLINDER (Continued)

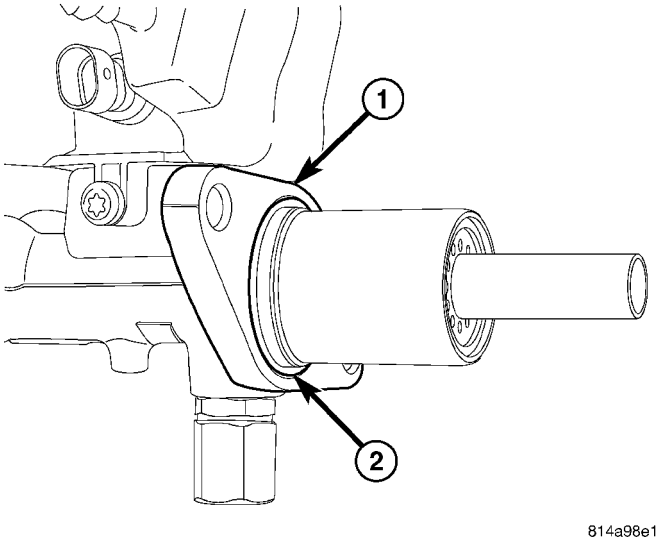

Fig. 91 Vacuum Seal On Rear Of Master Cylinder

1 - MASTER CYLINDER MOUNTING FLANGE
2 - VACUUM SEAL

(5) Install the two master cylinder mounting nuts (Fig. 78). Bosch Master Cylinder – Tighten each nut to 18 N·m (160 in. lbs.). Continental Teves Master Cylinder – Tighten each nut to 25 N·m (221 in. lbs.).

(6) Continental Teves Master Cylinder Only – If equipped with a manual transaxle and a new reservoir is being installed, using an appropriate cutting tool, cut the clutch actuator port at "V" groove opening the port. Discard the severed plug (Fig. 92).

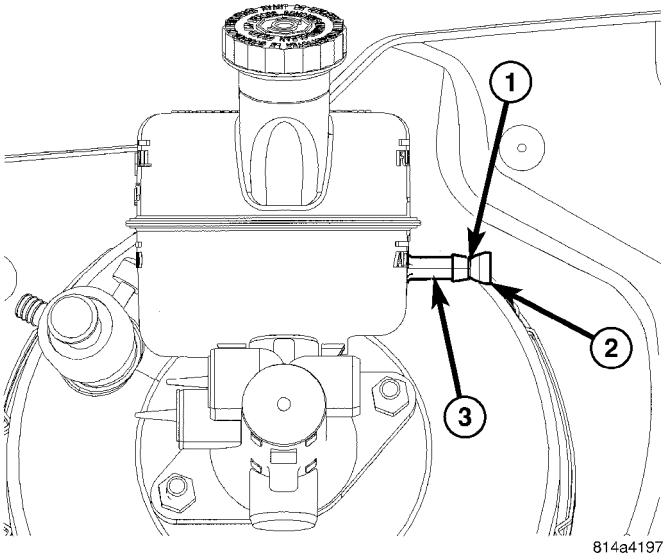

Fig. 92 Cut And Remove End Of Port - Manual Transaxle Only

1 - CUT AT CENTER OF "V" GROOVE
2 - PORT PLUG
3 - HYDRAULIC CLUTCH PORT

(7) Continental Teves Master Cylinder Only – If equipped with a manual transaxle, slide the clutch actuator hose onto the reservoir port (Fig. 93). Install the hose clamp just past the upset bead on the port.

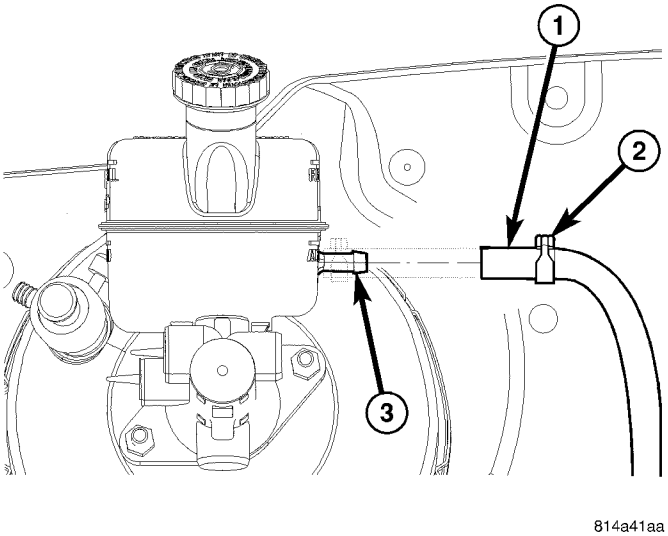

Fig. 93 Clutch Actuator Hose To Reservoir Port Installation

1 - CLUTCH ACTUATOR HOSE
2 - HOSE CLAMP
3 - UPSET BEAD ON PORT

(8) Connect the primary and secondary brake tubes to the master cylinder outlet ports (Fig. 76). Tighten tube nuts to 17 N·m (145 in. lbs.).

(9) Connect the brake fluid level switch wiring connector (Fig. 75).

(10) Install the power distribution center.

(11) Connect the negative (ground) cable on the battery.

(12) Install the air cleaner housing.

(13) Reinstall the air cleaner cover.

(14) Fill the master cylinder reservoir to the proper level. (Refer to 5 - BRAKES/HYDRAULIC/MECHANICAL/FLUID - STANDARD PROCEDURE)

WARNING: Be certain a firm brake pedal is achieved prior to attempting to operate the vehicle. If a firm brake pedal cannot be achieved, bleed the brake hydraulic system and check for leaks. (Refer to 5 - BRAKES - STANDARD PROCEDURE)

(15) Road test the vehicle to ensure proper operation of the brakes.

MASTER CYLINDER (Continued)

INSTALLATION - LHD WITHOUT ABS

(1) If removed, install the proportioning valves in their master cylinder ports (Fig. 83). The valves are identical, so they can be installed in either master cylinder port going to the rear brakes. Make sure the O-rings on the proportioning valves are new. Tighten the proportioning valves to 27 N·m (239 in. lbs.).

NOTE: The master cylinder must be bled before installing it on the vehicle.

(2) Bleed the master cylinder. (Refer to 5 - BRAKES/HYDRAULIC/MECHANICAL/MASTER CYLINDER - STANDARD PROCEDURE)

(3) Wipe the face of the power brake booster clean where the master cylinder seal comes in contact when it's installed. Do not get any cleaner or debris inside the booster.

CAUTION: When installing a master cylinder on the vehicle, a NEW vacuum seal MUST be installed on master cylinder (Fig. 94).

(4) If the master cylinder does not have a new vacuum seal installed on the mounting flange, remove it. Install a NEW vacuum seal on the master cylinder mounting flange making sure the seal fits squarely in its groove (Fig. 94).

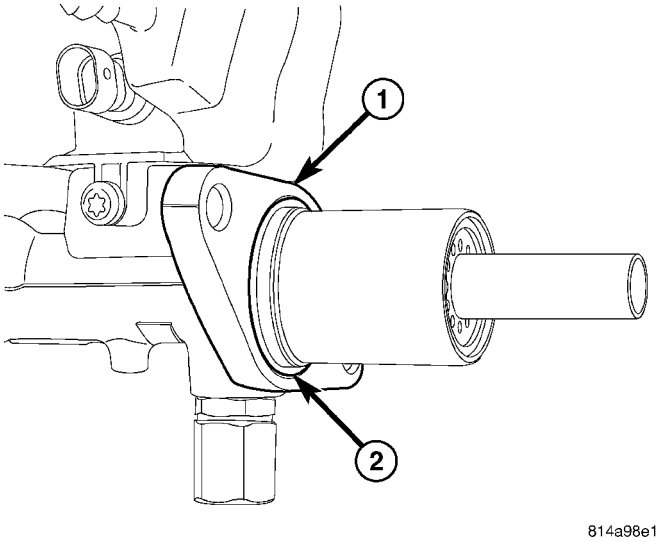

Fig. 94 Vacuum Seal On Rear Of Master Cylinder

1 - MASTER CYLINDER MOUNTING FLANGE
2 - VACUUM SEAL

CAUTION: If resistance is met during master cylinder insertion into power brake booster, the master cylinder push rod may not be lined up with the booster push rod. Remove the master cylinder, realign and insert it again.

(5) Line the master cylinder mounting holes up with the mounting studs on the power brake booster. Ensure the master cylinder piston push rod lines up with the booster push rod, then carefully slide the master cylinder into the power brake booster until it contacts the face of the booster.

(6) Install the two master cylinder mounting nuts (Fig. 82). Bosch Master Cylinder – Tighten each nut to 18 N·m (160 in. lbs.). Continental Teves Master Cylinder – Tighten each nut to 25 N·m (221 in. lbs.).

(7) Continental Teves Master Cylinder Only – If equipped with a manual transaxle and a new reservoir is being installed, using an appropriate cutting tool, cut the clutch actuator port at the "V" groove opening the port. Discard the severed plug (Fig. 95).

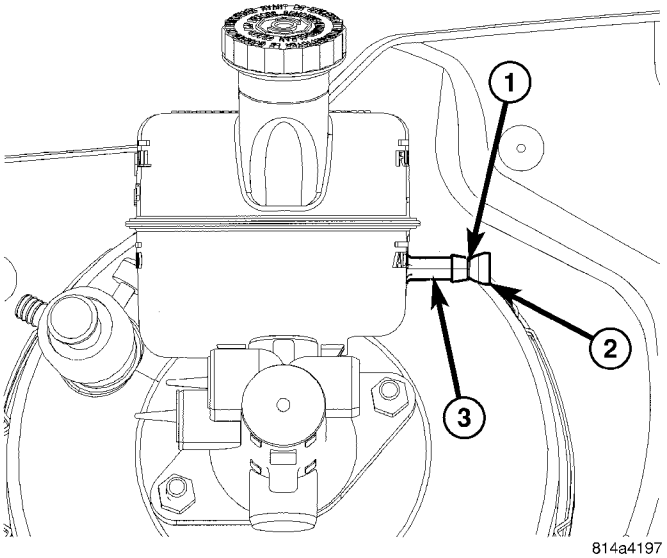

Fig. 95 Cut And Remove End Of Port - Manual Transaxle Only

1 - CUT AT CENTER OF "V" GROOVE
2 - PORT PLUG
3 - HYDRAULIC CLUTCH PORT

(8) Continental Teves Master Cylinder Only – If equipped with a manual transaxle, slide the clutch actuator hose onto the reservoir port (Fig. 96). Install the hose clamp just past the upset bead on the port.

(9) Connect the four brake tubes to the master cylinder and proportioning valve ports (Fig. 80). Tighten the tube nuts to a torque of 17 N·m (145 in. lbs.).

(10) Connect the brake fluid level switch wiring connector (Fig. 79).

(11) Install the power distribution center.

(12) Connect the negative (ground) cable on the battery.

(13) Install the air cleaner housing.

(14) Reinstall the air cleaner cover (two clips).

(15) Fill the master cylinder to the proper level. (Refer to 5 - BRAKES/HYDRAULIC/MECHANICAL/FLUID - STANDARD PROCEDURE)

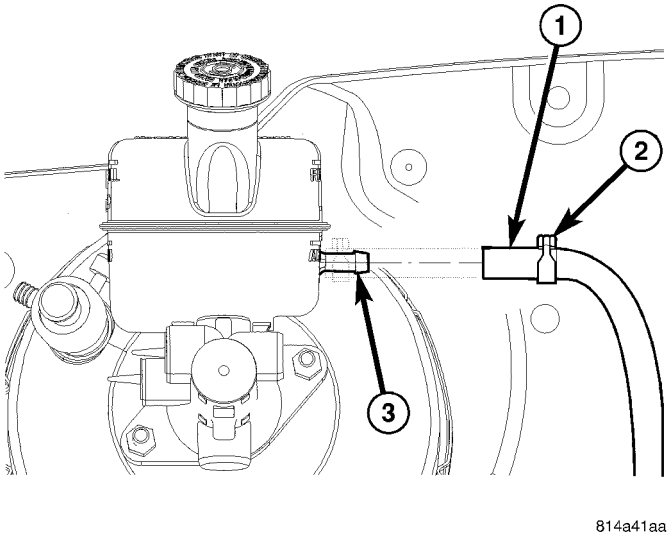

Fig. 96 Clutch Actuator Hose To Reservoir Port Installation

1 - CLUTCH ACTUATOR HOSE
2 - HOSE CLAMP
3 - UPSET BEAD ON PORT

WARNING: Be certain a firm brake pedal is achieved prior to attempting to operate the vehicle. If a firm brake pedal cannot be achieved, bleed the brake hydraulic system and check for leaks. (Refer to 5 - BRAKES - STANDARD PROCEDURE)

(16) Road test the vehicle to ensure proper operation of the brakes.

INSTALLATION - RHD

NOTE: The master cylinder must be bled before installing it on the vehicle.

(1) Bleed the master cylinder. (Refer to 5 - BRAKES/HYDRAULIC/MECHANICAL/MASTER CYLINDER - STANDARD PROCEDURE)

(2) Wipe the face of the power brake booster clean where the master cylinder seal comes in contact when it's installed. Do not get any cleaner or debris inside the booster.

CAUTION: When installing a master cylinder on the vehicle, a NEW vacuum seal MUST be installed on master cylinder (Fig. 97).

(3) If the master cylinder does not have a new vacuum seal installed on the mounting flange, remove it. Install a NEW vacuum seal on the master cylinder mounting flange making sure the seal fits squarely in its groove (Fig. 97).

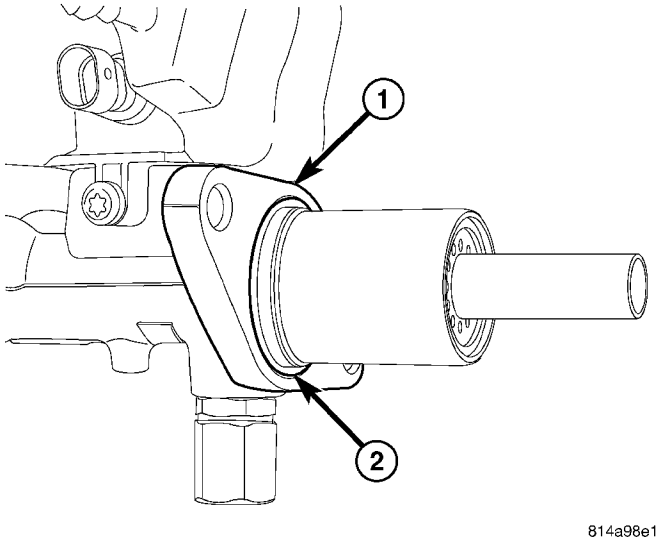

Fig. 97 Vacuum Seal On Rear Of Master Cylinder

1 - MASTER CYLINDER MOUNTING FLANGE
2 - VACUUM SEAL

CAUTION: If resistance is met during master cylinder insertion into power brake booster, the master cylinder push rod may not be lined up with the booster push rod. Remove the master cylinder, realign and insert it again.

(4) Line the master cylinder mounting holes up with the mounting studs on the power brake booster. Ensure the master cylinder piston push rod lines up with the booster push rod, then carefully slide the master cylinder into the power brake booster until it contacts the face of the booster.

(5) Install the two master cylinder mounting nuts (Fig. 86). Bosch Master Cylinder – Tighten each nut to 18 N·m (160 in. lbs.). Continental Teves Master Cylinder – Tighten each nut to 25 N·m (221 in. lbs.).

(6) Continental Teves Master Cylinder Only – If equipped with a manual transaxle and a new reservoir is being installed, using an appropriate cutting tool, cut the clutch actuator port at "V" groove opening the port. Discard the severed plug (Fig. 98).

(7) Continental Teves Master Cylinder Only – If equipped with a manual transaxle, slide the clutch actuator hose onto the reservoir port (Fig. 99). Install the hose clamp just past the upset bead on the port.

(8) Connect the primary and secondary brake tubes to the master cylinder (Fig. 84). Tighten all tube nuts to 17 N·m (145 in. lbs.).

(9) Connect the brake fluid level switch wiring connector.

(10) Install the brake booster vacuum supply hose.

(11) Fill the master cylinder to the proper level. (Refer to 5 - BRAKES/HYDRAULIC/MECHANICAL/FLUID - STANDARD PROCEDURE)

MASTER CYLINDER (Continued)

3 - UPSET BEAD ON PORT

WARNING: Be certain a firm brake pedal is achieved prior to attempting to operate the vehicle. If a firm brake pedal cannot be achieved, bleed the brake hydraulic system and check for leaks. (Refer to 5 - BRAKES - STANDARD PROCEDURE)

(12) Road test the vehicle to ensure proper operation of the brakes.

PEDAL - WITH AUTOMATIC TRANSAXLE

REMOVAL

NOTE: Before proceeding, (Refer to 5 - BRAKES - WARNING).

(1) Unclip the air cleaner cover (two clips) and move the cover aside.

(2) Disconnect and isolate the battery negative cable from its post on the battery.

(3) Remove the silencer pad below the knee blocker.

(4) Fold down and remove the knee blocker.

(5) Remove the brake lamp switch by rotating the switch in a counterclockwise direction approximately 30 degrees (Fig. 100).

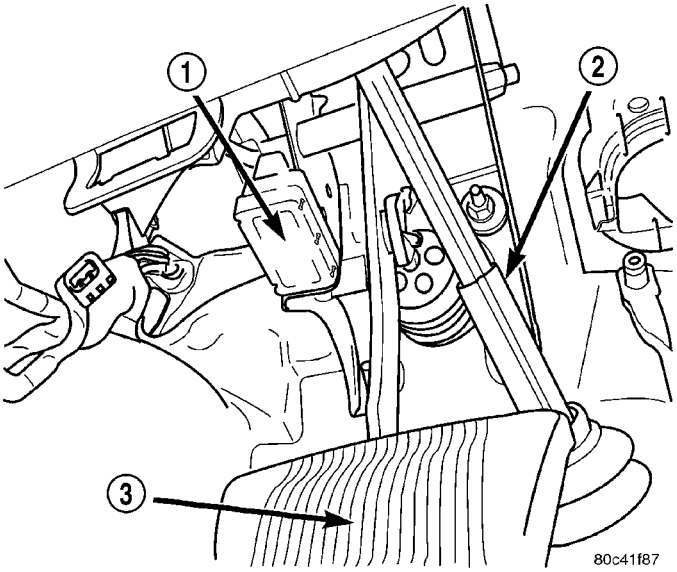

Fig. 100 Brake Lamp Switch

1 - BRAKE LAMP SWITCH
2 - STEERING COLUMN COUPLER
3 - BRAKE PEDAL

(6) Pull the switch rearward and remove it from its mounting bracket. Discard the brake lamp switch.

(7) Remove the clip securing the power brake booster input rod to the brake pedal (Fig. 101). Remove the input rod from the brake pedal.

(8) Remove the four nuts securing the power brake booster to the brake pedal bracket (Fig. 101).

(9) Remove the two remaining upper nuts securing the brake pedal bracket to the instrument panel support.

(10) Carefully remove the brake pedal and bracket assembly from the vehicle.

(11) Remove the pivot shaft nut.

PEDAL - WITH AUTOMATIC TRANSAXLE (Continued)

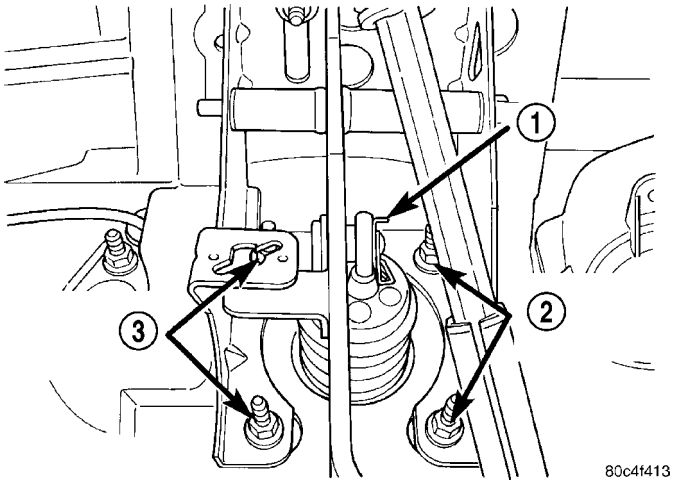

Fig. 101 Booster Mounting

1 - CLIP
2 - BOOSTER MOUNTING NUTS
3 - BOOSTER MOUNTING NUTS

(12) Remove the pivot shaft out the right side of the bracket.

(13) Slide the pedal out of its bracket.

(14) The bushings can be removed from the pedal by sliding them out each side of the pivot.

INSTALLATION

(1) Lubricate the brake pedal bushings with Mopar® Lubriplate or an equivalent.

(2) If removed, slide a bushing in each side of the pedal until the bushing shoulder contacts the pedal pivot.

(3) Install the brake pedal and bushings into the pedal mounting bracket by sliding the pedal between the sides of the bracket behind the brake lamp switch mounting flange.

(4) Once the pedal bushings line up with the mounting holes in the bracket, install the pivot shaft through the pedal from the right side.

(5) Install the pivot shaft nut. Tighten the nut to a torque of 34 N·m (25 ft. lbs.).

(6) Carefully install the brake pedal and bracket assembly in the vehicle lining up the bracket with the power brake booster mounting studs and the studs on the instrument panel support.

(7) Install the two upper nuts securing the brake pedal bracket to the instrument panel support. Install the two nuts all the way, but do not tighten them at this time.

(8) Install the four nuts securing the power brake booster to the brake pedal bracket (Fig. 101). Tighten the four nuts to a torque of 34 N·m (300 in. lbs.).

(9) Tighten the two upper nuts securing the brake pedal bracket to the instrument panel support to a torque of 34 N·m (300 in. lbs.).

(10) Install the power brake booster input rod on the pin mounted on the side of the brake pedal. Install a new retaining clip on the end of the pin (Fig. 101). Do not reuse the old clip.

CAUTION: Do not reuse the original brake lamp switch. The switch can only be adjusted once. That is during initial installation of the switch. If the switch is not adjusted properly or has been removed for some service, a new switch must be installed and adjusted.

(11) Mount and adjust the NEW brake lamp switch using the following procedure:

- Install the switch in its bracket by aligning the index tab on the switch with the slot in the mounting bracket.
- When the switch is fully seated in its bracket, rotate the switch clockwise approximately 30° to lock the switch into place (Fig. 100).
- With the brake pedal in the fully released position, move the lever on the back of the brake lamp switch from the non-adjusted angle position to the full vertical position (Fig. 102). This will adjust the brake lamp switch to the vehicle.

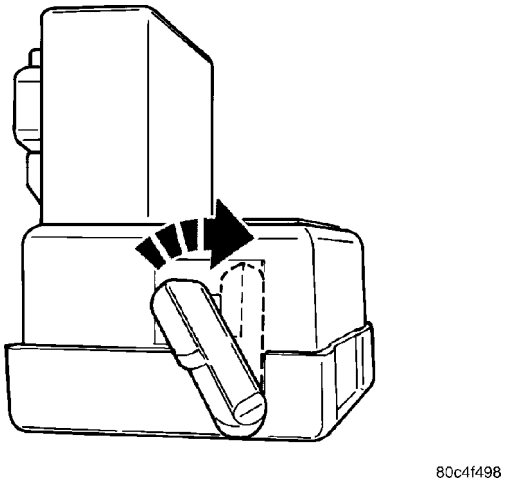

Fig. 102 Switch Adjustment Lever

(12) Install the knee blocker.

(13) Install the silencer pad below the knee blocker.

(14) Reconnect the battery negative terminal.

(15) Reinstall the air cleaner cover (two clips).

(16) Check the stop lamps to verify they are operating properly and not staying on when the pedal is in the released position.

(17) Road test the vehicle to ensure proper operation of the brakes and speed control (if equipped).

PEDAL - WITH MANUAL TRANSAXLE

REMOVAL

NOTE: Before proceeding, (Refer to 5 - BRAKES - WARNING).

(1) Unclip the air cleaner cover (two clips) and move the cover aside.

(2) Disconnect and isolate the battery negative cable from its post on the battery.

(3) Remove the silencer pad below the knee blocker.

(4) Fold down and remove the knee blocker.

(5) Remove the brake lamp switch by rotating the switch in a counterclockwise direction approximately 30 degrees (Fig. 103).

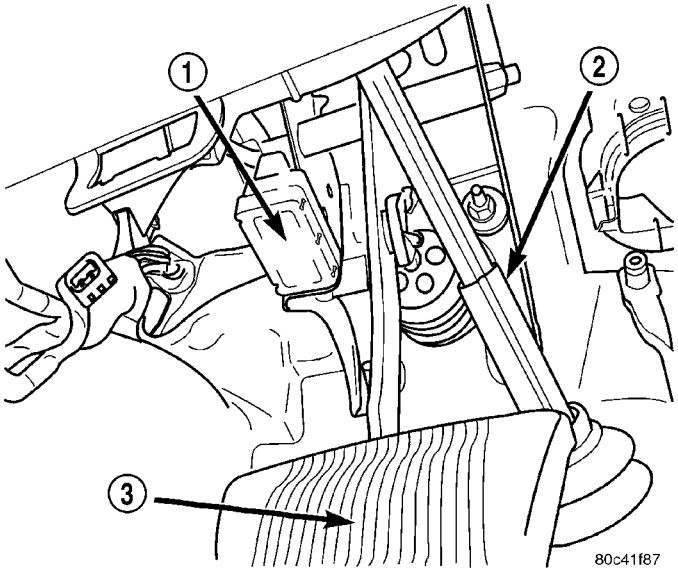

Fig. 103 Brake Lamp Switch

1 - BRAKE LAMP SWITCH
2 - STEERING COLUMN COUPLER
3 - BRAKE PEDAL

(6) Pull the switch rearward and remove it from its mounting bracket. Discard the brake lamp switch.

(7) Remove the clip securing the power brake booster input rod to the brake pedal (Fig. 104). Remove the input rod from the brake pedal.

(8) Remove the pivot shaft nut (Fig. 105).

(9) Start to remove the pivot shaft out the left side of the bracket (Fig. 105). Pull the shaft to the left until the brake pedal can be removed, stopping short of removing the shaft from the clutch pedal.

(10) Slide the brake pedal out of its bracket and remove it from the vehicle.

(11) The bushings can be removed from the pedal by sliding them out each side (Fig. 105).

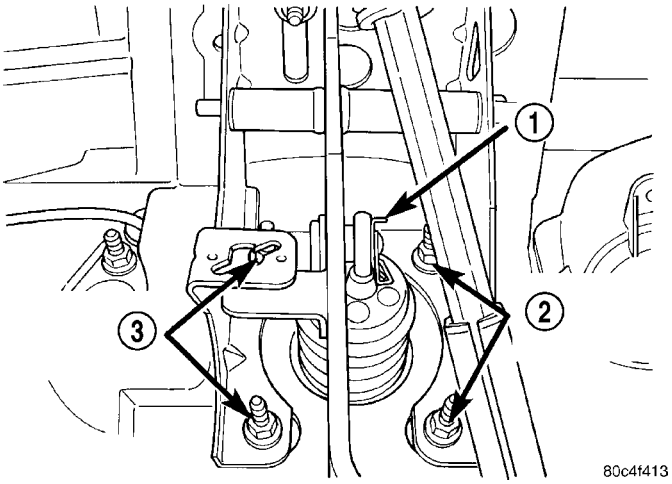

Fig. 104 Booster Push Rod Clip

1 - CLIP
2 - BOOSTER MOUNTING NUTS
3 - BOOSTER MOUNTING NUTS

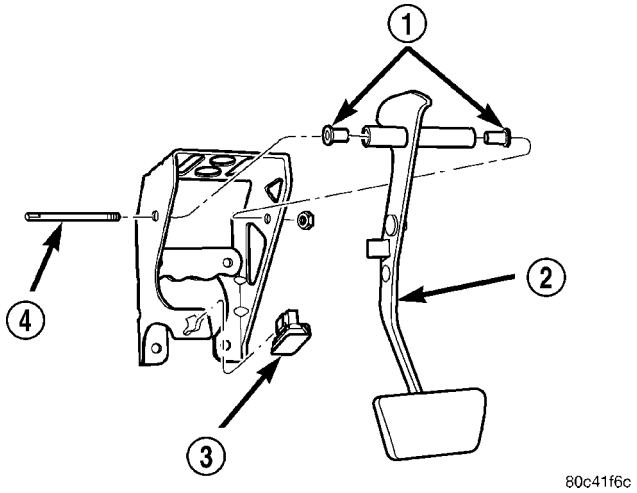

Fig. 105 Brake Pedal Mounting (Typical)

1 - BUSHINGS
2 - BRAKE PEDAL
3 - BRAKE LAMP SWITCH
4 - PIVOT SHAFT

INSTALLATION

(1) Lubricate the brake pedal bushings with Mopar® Lubriplate or an equivalent.

(2) If removed, slide a bushing in each side of the pedal pivot until the bushing shoulder contacts the pedal pivot.

(3) Install the brake pedal and bushings into the pedal mounting bracket by sliding the pedal between the sides of the bracket behind the brake lamp switch mounting flange (Fig. 105).

(4) Once the pedal bushings line up with the mounting holes in the bracket, install the pivot shaft through the pedal from the left side (Fig. 105).

PEDAL - WITH MANUAL TRANSAXLE (Continued)

(5) Install the pivot shaft nut (Fig. 105). Tighten the nut to a torque of 34 N·m (25 ft. lbs.).

(6) Install the power brake booster input rod on the pin mounted on the side of the brake pedal. Install a new retaining clip on the end of the pin (Fig. 104). Do not reuse the old clip.

CAUTION: Do not reuse the original brake lamp switch. The switch can only be adjusted once. That is during initial installation of the switch. If the switch is not adjusted properly or has been removed for some service, a new switch must be installed and adjusted.

(7) Mount and adjust the NEW brake lamp switch using the following procedure:

- Install the switch in its bracket by aligning the index tab on the switch with the slot in the mounting bracket.
- When the switch is fully seated in its bracket, rotate the switch clockwise approximately 30° to lock the switch into place (Fig. 103).
- With the brake pedal in the fully released position, move the lever on the back of the brake lamp switch from the non-adjusted angle position to the full vertical position (Fig. 106). This will adjust the brake lamp switch to the vehicle.

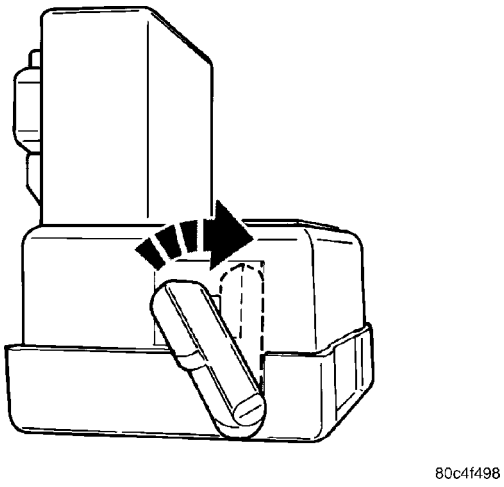

Fig. 106 Switch Adjustment Lever

(8) Install the knee blocker.

(9) Install the silencer pad below the knee blocker.

(10) Reconnect the battery negative terminal.

(11) Reinstall the air cleaner cover (two clips).

(12) Check the stop lamps to verify they are operating properly and not staying on when the pedal is in the released position.

(13) Road test the vehicle to ensure proper operation of the brakes and speed control (if equipped).

POWER BRAKE BOOSTER

DESCRIPTION

The power brake booster is mounted to the engine side of the dash panel. The master cylinder is bolted to the front of the booster (Fig. 107). A vacuum check valve is also mounted on the front of the booster. A vacuum line connects the check valve to engine source vacuum. The booster input rod extends through the dash panel and connects to the brake pedal.

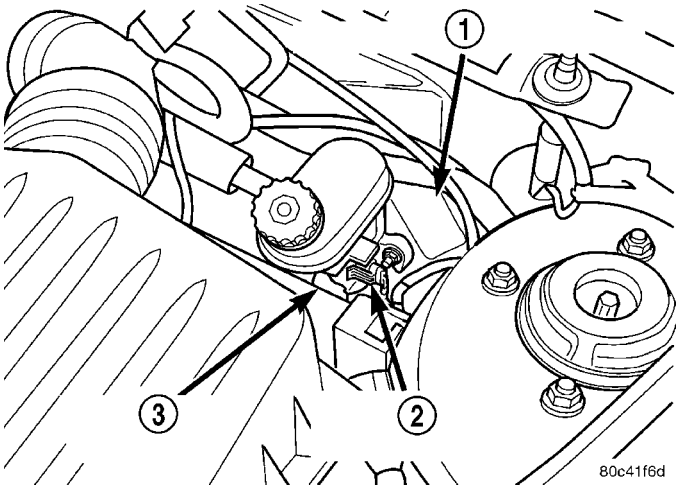

Fig. 107 Power Brake Booster Location

1 - POWER BRAKE BOOSTER
2 - BRAKE FLUID LEVEL SWITCH
3 - MASTER CYLINDER

There are two different power brake booster designs, although externally they appear similar. Early production vehicles (with Bosch master cylinder and booster) use a 205 mm tandem diaphragm power brake booster. Normal production vehicles (with Continental Teves master cylinder and booster) use a 200 mm tandem diaphragm power brake booster. Power brake boosters are internally tuned differently depending on whether the vehicle is equipped with ABS or without ABS. If the power brake booster requires replacement, be sure it is replaced with the correct part.

The power brake booster can be identified by the tag attached to the body of the booster assembly (Fig. 108). This tag contains the following information:

- The production part number
- The date it was built, and
- The booster manufacturer.

OPERATION

The purpose of the power brake booster is to reduce the amount of force required by the driver (foot-pedal pressure) to obtain the required hydraulic pressure in the brake system to stop the vehicle.

POWER BRAKE BOOSTER (Continued)

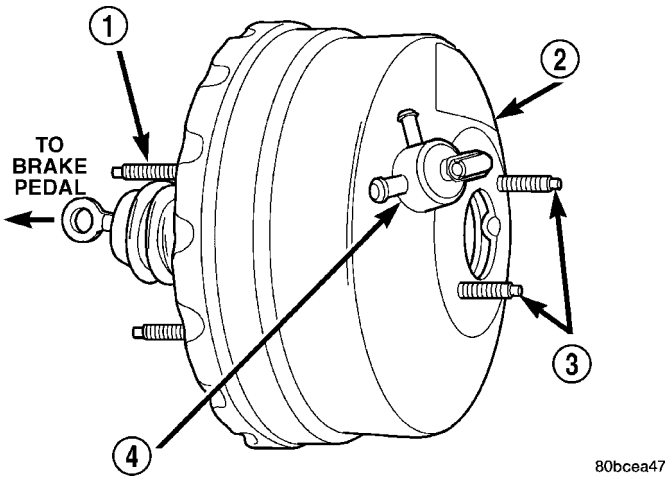

Fig. 108 Power Brake Booster

1 - MOUNTING STUD
2 - PARTS IDENTIFICATION TAG
3 - MASTER CYLINDER MOUNTING STUDS
4 - VACUUM CHECK VALVE

The power brake booster is vacuum operated. The vacuum is supplied from the intake manifold on the engine through the vacuum hose and power brake booster vacuum check valve.

As the brake pedal is depressed, the power booster input rod moves forward. This opens and closes valves in the power brake booster, allowing atmospheric pressure to enter on one side of a diaphragm. Engine vacuum is always present on the other side. This difference in pressure forces the output rod of the power booster out against the primary piston of the master cylinder. As the pistons in the master cylinder move forward, hydraulic pressure is created in the brake system.

DIAGNOSIS AND TESTING - POWER BRAKE BOOSTER

BASIC TEST

(1) With engine off, depress and release the brake pedal several times to purge all vacuum from the power brake booster.

(2) Depress and hold the pedal with light effort (15 to 25 lbs. pressure), then start the engine.

The pedal should fall slightly, then hold. Less effort should be needed to apply the pedal at this time. If the pedal fell as indicated, perform the VACUUM LEAK TEST listed after the BASIC TEST. If the pedal did not fall, continue on with this BASIC TEST.

(3) Disconnect the vacuum hose on the side of the vacuum check valve that leads to the speed control, then connect a vacuum gauge to the open vacuum port on the valve.

(4) Start the engine.

(5) When the engine is at warm operating temperature, allow it to idle and check the vacuum at the gauge.

If the vacuum supply is 12 inches Hg (40.5 kPa) or more, the power brake booster is defective and must be replaced. If the vacuum supply is below 12 inches, continue on with this BASIC TEST.

(6) Shut off the engine.

(7) Connect the vacuum gauge to the vacuum reference port on the engine intake manifold.

(8) Start the engine and observe the vacuum gauge.

If the vacuum is still low, check the engine tune and repair as necessary. If the vacuum is above 12 inches, the hose or check to the booster has a restriction or leak.

Once an adequate vacuum supply is obtained, repeat the BASIC TEST.

VACUUM LEAK TEST

(1) Disconnect the vacuum hose on the side of the power brake booster vacuum check valve that leads to the speed control, then connect a vacuum gauge to the open vacuum port on the valve.

(2) Remove the remaining hose on the vacuum check valve that is not the vacuum supply hose coming from the intake manifold. Cap off the open port on the check valve.

(3) Start the engine.

(4) Allow the engine to warm up to normal operating temperature and engine idle.

(5) Using vacuum line pliers, close off the vacuum supply hose near the booster and observe the vacuum gauge.

If the vacuum drop exceeds 1.0 inch Hg (3.3 kPa) in one minute, repeat the above steps to confirm the reading. The vacuum loss should be less than 1.0 inch Hg in one minute time span. If the loss is more than 1.0 inch Hg, replace the power brake booster. If it is not, continue on with this test.

(6) Remove the pliers from the hose temporarily.

(7) Apply light effort (approximately 15 lbs. of force) to the brake pedal and hold the pedal steady. Do not move the pedal once the pressure is applied or the test results may vary.

(8) Have an assistant reattach the pliers to the vacuum supply hose.

(9) Allow 5 seconds for stabilization, then observe the vacuum gauge.

If the vacuum drop exceeds 3.0 inches Hg (10 kPa) in 15 seconds, repeat the above steps to confirm the reading. The vacuum loss should be less than 3.0 inches Hg in 15 seconds time span. If the loss is more than 3.0 inches Hg, replace the power brake booster. If it is not, the booster is not defective.

POWER BRAKE BOOSTER (Continued)

REMOVAL

REMOVAL - LHD

NOTE: Before proceeding, (Refer to 5 - BRAKES - WARNING) (Refer to 5 - BRAKES - CAUTION).

(1) Disconnect negative (ground) cable from the battery and isolate the cable.

(2) Remove the master cylinder. (Refer to 5 - BRAKES/HYDRAULIC/MECHANICAL/MASTER CYLINDER - REMOVAL)

(3) If the vehicle is equipped with ABS, remove the integrated control unit (ICU). (Refer to 5 - BRAKES/ HYDRAULIC/MECHANICAL/ICU (INTEGRATED CONTROL UNIT) - REMOVAL)

(4) Disconnect the vacuum hoses from the check valve on the power brake booster (Fig. 109), but do not remove the check valve from power brake booster.

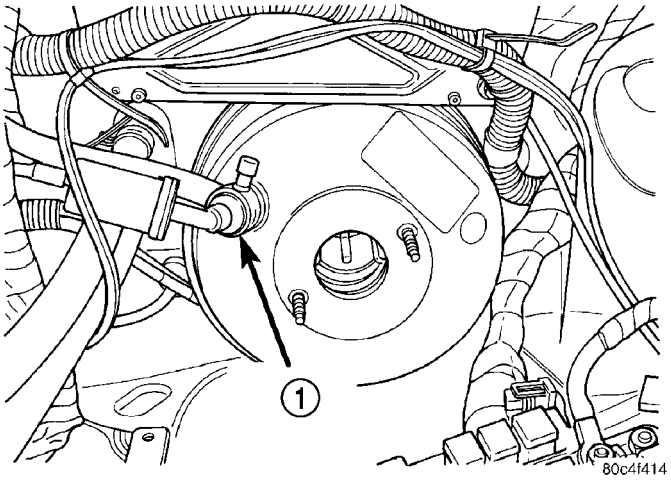

Fig. 109 Vacuum Check Valve

1 - VACUUM CHECK VALVE

(5) Inside the vehicle, remove the silencer pad below the knee blocker.

(6) Fold down and remove the knee blocker.

(7) Locate the brake pedal-to-power brake booster input rod attachment under the instrument panel. Position a small screwdriver under the center tang of the retaining clip (Fig. 110). Rotate the screwdriver enough to allow the retaining clip tang to pass over the end of the brake pedal pin. Remove the clip.

CAUTION: Discard the used retaining clip, it is not to be reused. Replace the clip with a new one on reassembly.

(8) Remove the four nuts attaching the power brake booster to the instrument panel (Fig. 111). The nuts are accessible from under the instrument panel in the area of the brake pedal bracket.

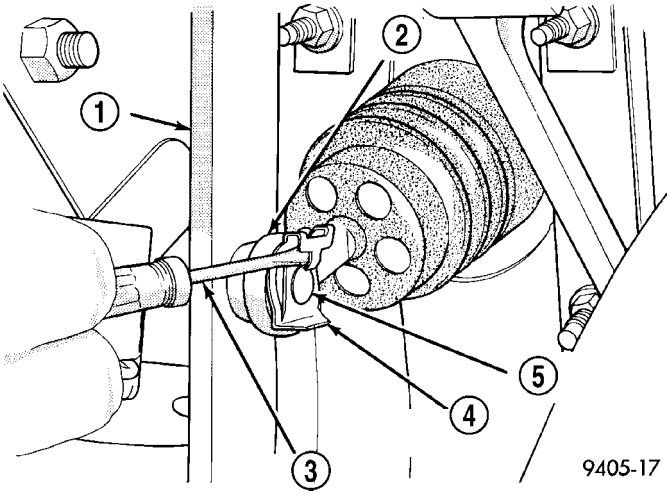

Fig. 110 Retaining Clip

1 - BRAKE PEDAL
2 - INPUT ROD
3 - SCREWDRIVER
4 - RETAINING CLIP
5 - BRAKE PEDAL PIN

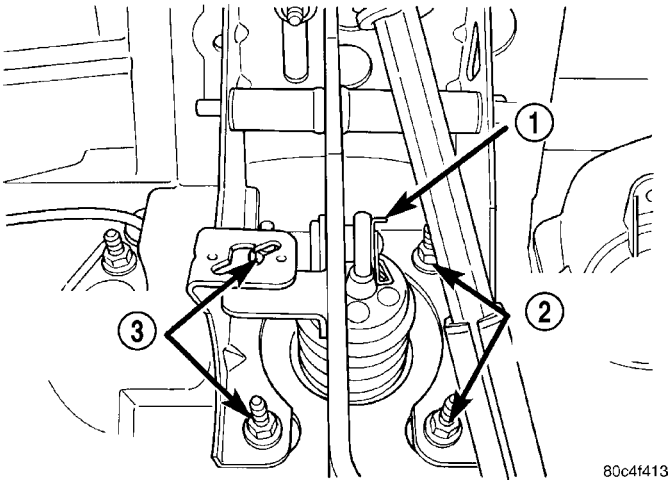

Fig. 111 Power Brake Booster Mounting

1 - CLIP
2 - BOOSTER MOUNTING NUTS
3 - BOOSTER MOUNTING NUTS

(9) Slide the power brake booster forward until mounting studs clear the instrument panel, then remove it from the vehicle.

REMOVAL - RHD

NOTE: Before proceeding, (Refer to 5 - BRAKES - WARNING) (Refer to 5 - BRAKES - CAUTION).

(1) Disconnect negative (ground) cable from the battery and isolate the cable.

(2) Using a R-134a refrigerant recovery machine, remove the refrigerant from the A/C system. (Refer to

POWER BRAKE BOOSTER (Continued)

24 - HEATING & AIR CONDITIONING - STANDARD PROCEDURE)

(3) Disconnect the refrigerant lines at their mid-line connection block just above the upper engine torque strut. Position the refrigerant lines out of the way and cap all openings to prevent contamination.

(4) Remove the master cylinder. (Refer to 5 - BRAKES/HYDRAULIC/MECHANICAL/MASTER CYLINDER - REMOVAL)

(5) Inside the vehicle, remove the silencer pad below the knee blocker.

(6) Fold down and remove the knee blocker.

(7) Locate the brake pedal-to-power brake booster input rod attachment under the instrument panel. Position a small screwdriver under the center tang of the retaining clip (Fig. 110), then rotate the screwdriver enough to allow the retaining clip tang to pass over the end of the brake pedal pin. Remove the clip.

CAUTION: Discard the used retaining clip, it is not to be reused. Replace the clip with a new one on reassembly.

(8) Remove the four nuts attaching the power brake booster to the instrument panel. The nuts are accessible from under the instrument panel in the area of the brake pedal bracket.

(9) Slide the power brake booster forward until mounting studs clear the dash panel, then remove it from engine compartment by carefully positioning booster lip past edge of engine cover. Use care to prevent breaking valve cover.

INSTALLATION

INSTALLATION - LHD

NOTE: Before power brake booster installation, be certain dash seal is installed on booster mounting studs.

(1) Install the power brake booster by sliding the input rod and studs through the dash panel and into mounting position.

(2) Under the instrument panel, install the four power brake booster mounting nuts (Fig. 111). Tighten the nuts to a torque of 34 N·m (25 ft. lbs.).

(3) Using Mopar® Lubriplate, or an equivalent, coat the surface of the brake pedal pin where it contacts the brake booster input rod.

CAUTION: Use only a new brake booster input rod-to-brake pedal retaining clip to ensure proper retainment.

(4) Connect the power brake booster input rod-to-brake pedal pin. Install a new retaining clip. Do not use the old clip.

CAUTION: Do not reuse the original brake lamp switch. The switch can only be adjusted once. That is during initial installation of the switch. If the switch is not adjusted properly or has been removed for some service, a new switch must be installed and adjusted.

(5) Remove and replace the brake lamp switch with a NEW switch. Discard the original brake lamp switch. (Refer to 8 - ELECTRICAL/LAMPS/LIGHTING - EXTERIOR/BRAKE LAMP SWITCH - REMOVAL) (Refer to 8 - ELECTRICAL/LAMPS/LIGHTING - EXTERIOR/BRAKE LAMP SWITCH - INSTALLATION)

(6) Install the knee blocker.

(7) Install the silencer pad below the knee blocker.

CAUTION: When installing the vacuum hoses onto the check valve, make sure the hoses are routed properly to avoid possible contact with the exhaust manifold and other unfriendly surfaces.

(8) Connect all previously removed vacuum hoses to the vacuum check valve (Fig. 109).

(9) If the vehicle is equipped with ABS, reinstall the ICU. (Refer to 5 - BRAKES/HYDRAULIC/MECHANICAL/ICU (INTEGRATED CONTROL UNIT) - INSTALLATION)

(10) Install the master cylinder. (Refer to 5 - BRAKES/HYDRAULIC/MECHANICAL/MASTER CYLINDER - INSTALLATION)

(11) Install the power distribution center.

(12) Connect the negative (ground) cable on the battery.

(13) Install the air cleaner housing.

(14) Reinstall the air cleaner cover and hose to throttle body.

(15) Bleed the base brake system and ABS. (Refer to 5 - BRAKES - STANDARD PROCEDURE)

(16) Road test the vehicle to ensure proper operation of the brakes.

INSTALLATION - RHD

(1) Install the brake booster on the dash panel using the reverse of how it was removed. Be certain dash seal is installed on booster studs prior to installation.

(2) Under the instrument panel, install the four power brake booster mounting nuts. Tighten the nuts to a torque of 34 N·m (25 ft. lbs.).

(3) Using Mopar® Lubriplate, or an equivalent, coat the surface of the brake pedal pin where it contacts the brake booster input rod.

POWER BRAKE BOOSTER (Continued)

CAUTION: Use only a new brake booster input rod-to-brake pedal retaining clip to ensure proper retainment.

(4) Connect the power brake booster input rod-to-brake pedal pin. Install a new retaining clip. Do not use the old clip.

CAUTION: Do not reuse the original brake lamp switch. The switch can only be adjusted once. That is during initial installation of the switch. If the switch is not adjusted properly or has been removed for some service, a new switch must be installed and adjusted.

(5) Remove and replace the brake lamp switch with a NEW switch. Discard the original brake lamp switch. (Refer to 8 - ELECTRICAL/LAMPS/LIGHTING - EXTERIOR/BRAKE LAMP SWITCH - REMOVAL) (Refer to 8 - ELECTRICAL/LAMPS/LIGHTING - EXTERIOR/BRAKE LAMP SWITCH - INSTALLATION)

(6) Install the knee blocker.

(7) Install the silencer pad below the knee blocker.

(8) Install the master cylinder on the vehicle. (Refer to 5 - BRAKES/HYDRAULIC/MECHANICAL/MASTER CYLINDER - INSTALLATION)

(9) Remove the caps and connect refrigerant lines. Be certain the sealing O-rings are well lubricated with PAG oil and free of tears. Torque the retaining fastener to 40 in. lbs.

(10) Using a R-134a refrigerant recovery machine, evacuate and charge the refrigerant system. (Refer to 24 - HEATING & AIR CONDITIONING - STANDARD PROCEDURE)

(11) Connect the negative (ground) cable on the battery.

WARNING: Be certain a firm brake pedal is achieved prior to attempting to operate the vehicle.

(12) Road test the vehicle to ensure proper operation of the brakes.

PROPORTIONING VALVE

DESCRIPTION

NOTE: Only vehicles without antilock brakes have proportioning valves. Vehicles with antilock brakes have Electronic Variable Brake Proportioning (EVBP) that is built into the integrated control unit.

On the non-antilock master cylinder, two screw-in proportioning valves are screwed directly into the rear brake outlet ports (Fig. 117). The chassis brake tubes leading to the rear brakes attach to the outlets of the proportioning valves. One proportioning valve controls each rear brake.

OPERATION

Proportioning valves balance front to rear braking by controlling the brake fluid hydraulic pressure to the rear brakes above a preset level (split point). Under light pedal application, the proportioning valve allows normal fluid flow to the rear brakes. Under higher pedal effort, the valve reduces fluid pressure to the rear brakes. This helps prevent rear wheel skid tendencies.

DIAGNOSIS AND TESTING - PROPORTIONING VALVE

NOTE: Only vehicles without antilock brakes have proportioning valves. Vehicles with antilock brakes have Electronic Variable Brake Proportioning (EVBP) which is built into the ABS Integrated Control Unit (ICU).

If premature rear wheel skid occurs on a hard brake application, it could be an indication that a malfunction has occurred with one of the proportioning valves.

One proportioning valve controls the right rear brake and the other proportioning valve controls the left rear brake (Fig. 112). Therefore, a road test to determine which rear brake skids first is essential.

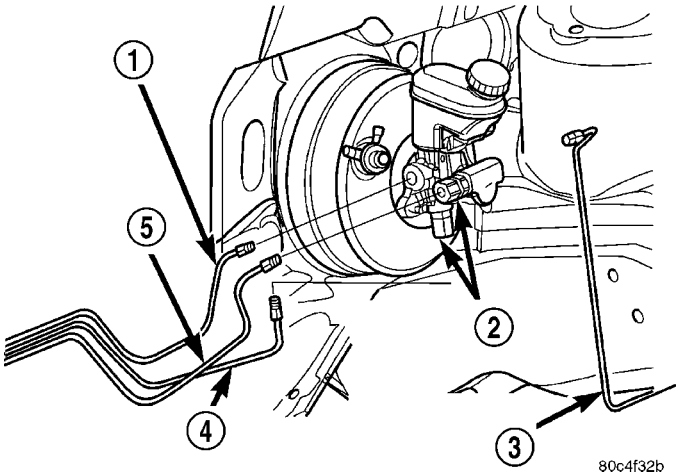

Fig. 112 Proportioning Valve Location

1 - RIGHT FRONT BRAKE TUBE
2 - PROPORTIONING VALVES
3 - LEFT FRONT BRAKE TUBE
4 - LEFT REAR BRAKE TUBE
5 - RIGHT REAR BRAKE TUBE

Before testing the proportioning valve in question, inspect the rear brake linings for contamination or for replacement shoes not meeting the OEM brake lining material specifications.

The proportioning valve should always be tested prior to being replaced.

PROPORTIONING VALVE (Continued)

The in-line proportioning valves used on this vehicle require special pressure fittings to test the proportioning valves for proper proportioning valve function. The pressure fittings are installed before and after the proportioning valve being tested to verify proportioning valve is maintaining the required hydraulic pressure to the rear wheel brake which it controls.

PROPORTIONING VALVE TEST

The test procedure is the same for either rear proportioning valve. After road testing the vehicle to determine which wheel skids first, follow the procedure below for testing the suspect proportioning valve.

(1) Using a brake pedal holding tool as shown (Fig. 113), depress the brake pedal past its first one inch of travel and hold it in this position. This will isolate the master cylinder from the brake hydraulic system and will not allow the brake fluid to drain out of the master cylinder reservoir.

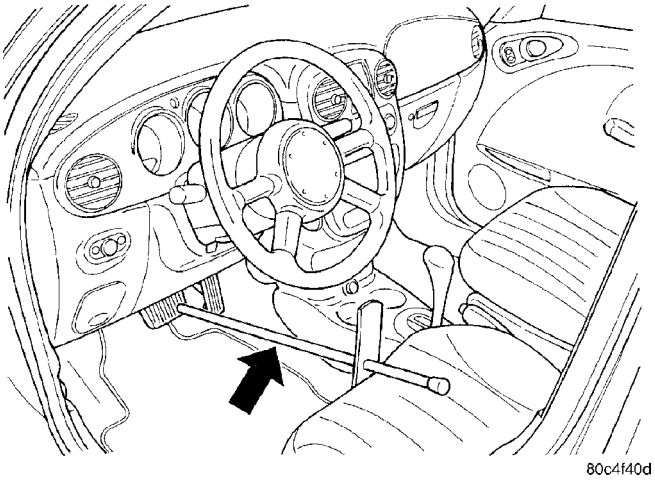

Fig. 113 Brake Pedal Holding Tool

(2) Use the figure shown to determine which proportioning valve needs to be tested (Fig. 112).

(3) Remove the hydraulic brake tube from the proportioning valve controlling the rear wheel of the vehicle that has premature wheel skid.

(4) Remove the proportioning valve from its outlet port on the master cylinder.

CAUTION: Be sure the pressure test fittings being installed into master cylinder and proportioning valve, have the correct thread sizes needed.

(5) Install the Brake Pressure Adapters, Special Tool 8644 and 8187-2 onto the proportioning valve (Fig. 114).

(6) Install the proportioning valve (with tools) back into the outlet port on the master cylinder.

(7) Attach a Pressure Gauge, Special Tool C-4007-A, to each pressure adapter (Fig. 115).

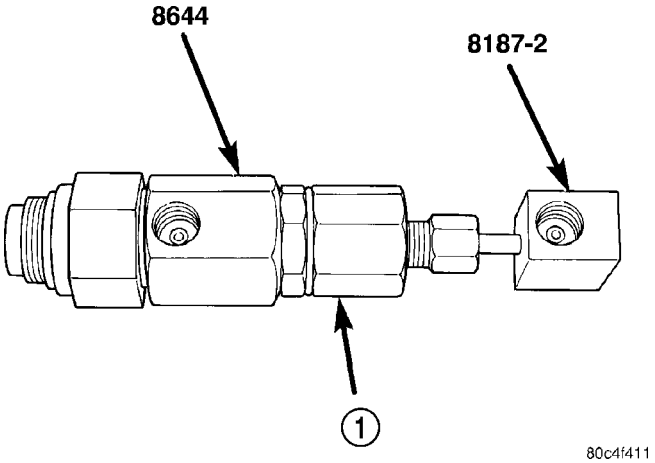

Fig. 114 Tools On Valve

1 - PROPORTIONING VALVE

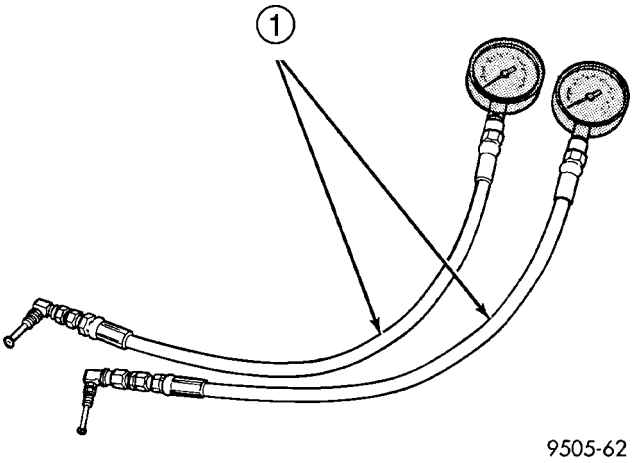

Fig. 115 Pressure Gauge Set

1 - SPECIAL TOOL C-4007–A

(8) Remove the brake pedal holding tool. Bleed any air out of the pressure gauge hoses at the pressure gauge.

(9) With the aid of a helper, apply pressure to the brake pedal until the reading on proportioning valve inlet gauge is at the target inlet pressure shown in the Brake Proportioning Valve Applications And Pressure Specifications table following this procedure. If the inlet gauge pressure overshoots its target pressure when the pedal is depressed, release the brake pedal, relieving the pressure in the system, before reapplying the pedal to reach the target pressure at the inlet gauge. This is necessary to get an accurate reading of the outlet pressure.

(10) Once inlet pressure has been achieved, check the pressure reading on the proportioning valve outlet gauge. If the proportioning valve outlet pressure does not agree with value shown in the table, replace the proportioning valve. If proportioning valve is within pressure specifications, the valve is good and does not require replacement.

PROPORTIONING VALVE (Continued)

(11) Reinstall the brake holding tool on the brake pedal and remove the test equipment from the vehicle.

(12) Remove the tools from the proportioning valve.

(13) Install the proportioning valve in the master cylinder and hand tighten until the proportioning valve is fully installed and its O-ring seal is seated into the master cylinder. Tighten the proportioning valve to a torque of 40 N·m (30 ft. lbs.).

(14) Install the brake tube on the proportioning valve. Tighten the tube nut to a torque of 17 N·m (145 in. lbs.).

(15) Bleed the affected brake line. (Refer to 5 - BRAKES - STANDARD PROCEDURE)

BRAKE PROPORTIONING VALVE APPLICATIONS AND PRESSURE SPECIFICATIONS

SALES CODE	BRAKE SYSTEM TYPE	SPLIT POINT	SLOPE	INLET PRESSURE	OUTLET PRESSURE
BRB	15 In. Disc/Drum	380 psi	0.27	1000 psi	500-600 psi

REMOVAL

NOTE: Before proceeding, (Refer to 5 - BRAKES - WARNING) (Refer to 5 - BRAKES - CAUTION).

(1) Using a brake pedal holder, depress the brake pedal past its first one inch of travel and hold it in this position (Fig. 116). This will isolate the master cylinder from the brake hydraulic system and will not allow the brake fluid to drain out of the master cylinder reservoir.

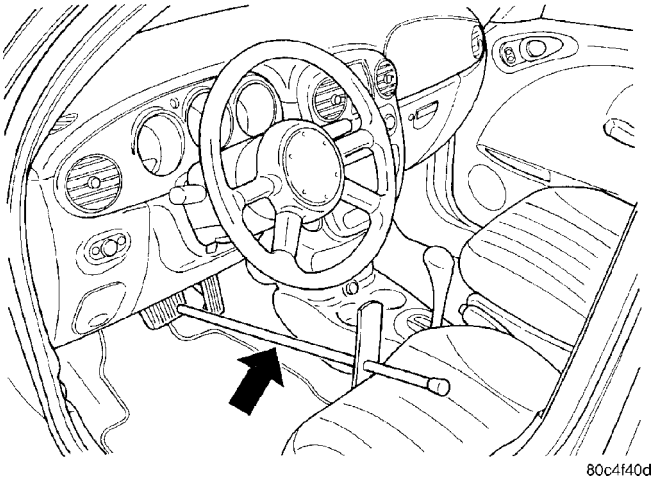

Fig. 116 Brake Pedal Holder

NOTE: To access the lower (left rear) proportioning valve, it may help to remove the air cleaner cover and hose to the throttle body.

(2) Disconnect the brake tube from the proportioning valve requiring removal (Fig. 117).

(3) Unscrew the Proportioning valve from the master cylinder.

INSTALLATION

(1) Lubricate the O-ring on the proportioning valve. Make sure the O-ring on the proportioning valve is new.

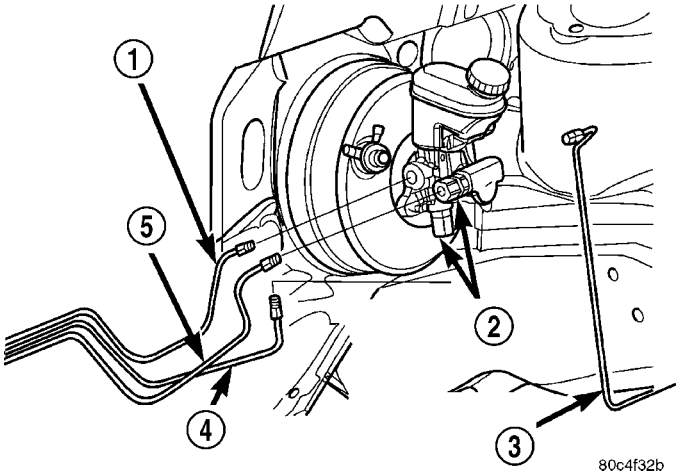

Fig. 117 Proportioning Valves On Master Cylinder

1 - RIGHT FRONT BRAKE TUBE
2 - PROPORTIONING VALVES
3 - LEFT FRONT BRAKE TUBE
4 - LEFT REAR BRAKE TUBE
5 - RIGHT REAR BRAKE TUBE

(2) Install the proportioning valve in its master cylinder port. Tighten the proportioning valve to a torque of 40 N·m (30 ft. lbs.).

(3) Connect the brake tube to the proportioning valve (Fig. 117). Tighten the tube nut to a torque of 17 N·m (145 in. lbs.).

NOTE: Reinstall the air cleaner cover and hose if earlier removed to gain more access to the lower (left rear) proportioning valve.

(4) Remove the brake pedal holder (Fig. 116).

(5) Bleed the affected brake line. (Refer to 5 - BRAKES - STANDARD PROCEDURE)

(6) Road test the vehicle to ensure proper operation of the brakes.

ROTOR

DESCRIPTION

There are two different size rotors available depending on brake application. Vehicles with the brake sales code BRB and BRK (Disc/Drum combinations) and BRT (Disc/Disc combination) use standard size brake rotors. Vehicles equipped with the brake sales code BR4 (Performance Disc/Disc combination) use heavier brake rotors. The BR4 front brake rotor is approximately 5 mm thicker than the standard front brake rotor. The BR4 rear brake rotor is approximately 3 mm thicker than the standard rear brake rotor. The BR4 brake rotors can be easily identified by the recessed machined area near the hub center (Fig. 118) (Fig. 119).

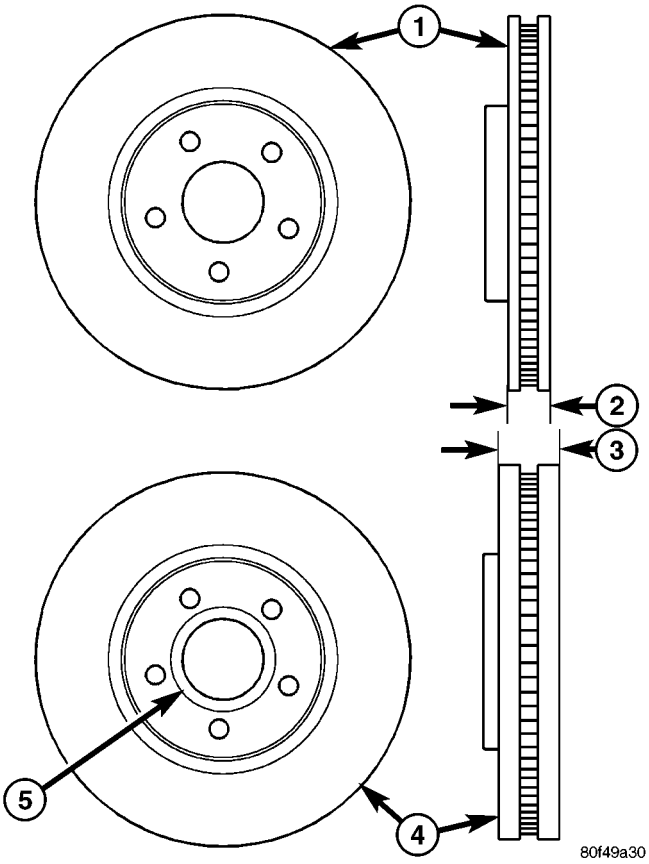

Fig. 118 Front Brake Rotor Comparison

1 - BRB/BRT BRAKE ROTOR
2 - STANDARD ROTOR THICKNESS 22.91-23.10 MM
3 - PERFORMANCE ROTOR THICKNESS 27.91-28.10 MM
4 - BR4 PERFORMANCE BRAKE ROTOR
5 - INDENTIFYING MACHINED AREA

DIAGNOSIS AND TESTING - BRAKE ROTOR

Any servicing of the rotor requires extreme care to maintain the rotor within service tolerances to ensure proper brake action.

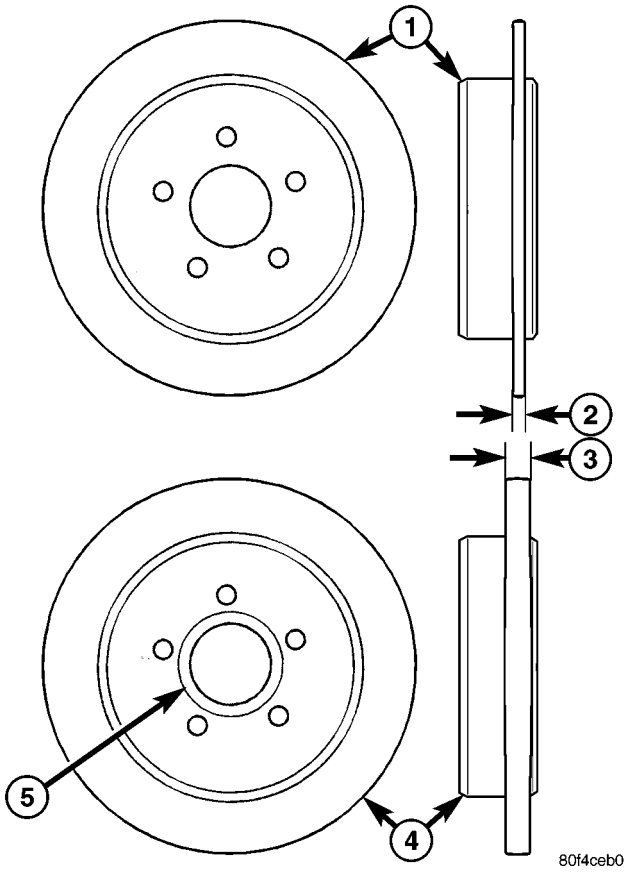

Fig. 119 Rear Brake Rotor Comparison

1 - BRT BRAKE ROTOR
2 - STANDARD ROTOR THICKNESS 8.75-9.25 MM
3 - PERFORMANCE ROTOR THICKNESS 11.75-12.25 MM
4 - BR4 PERFORMANCE BRAKE ROTOR
5 - INDENTIFYING MACHINED AREA

Excessive runout or wobble in a rotor can increase pedal travel due to piston knock-back. This increases guide pin sleeve wear due to the tendency of the caliper to follow the rotor wobble.

When diagnosing a brake noise or pulsation, the machined disc braking surface should be checked and inspected.

BRAKING SURFACE INSPECTION

Light braking surface scoring and wear is acceptable. If heavy scoring or warping is evident, the rotor must be refaced or replaced. (Refer to 5 - BRAKES/HYDRAULIC/MECHANICAL/ROTOR - STANDARD PROCEDURE)

Excessive wear and scoring of the rotor can cause improper lining contact on the rotor's braking surface. If the ridges on the rotor are not removed before new brake shoes are installed, improper wear of the shoes will result.

ROTOR (Continued)

If a vehicle has not been driven for a period of time, the rotor's braking surface will rust in the areas not covered by the brake shoes at that time. Once the vehicle is driven, noise and chatter from the disc brakes can result when the brakes are applied until the rust wears away.

Some discoloration or wear of the rotor surface is normal and does not require resurfacing when linings are replaced. If cracks or burned spots are evident, the rotor must be replaced.

ROTOR MINIMUM THICKNESS

Measure rotor thickness at the center of the brake shoe contact surface. Replace the rotor if it is worn below minimum thickness or if machining the rotor will cause its thickness to fall below specifications.

CAUTION: Do not machine (turn) the rotor if it will cause the rotor to fall below minimum thickness.

Minimum thickness specifications are cast on the rotor's unmachined surface (Fig. 120) (or stamped into the hat section). Limits can also be found in this section's specification table. (Refer to 5 - BRAKES/HYDRAULIC/MECHANICAL/ROTOR - SPECIFICATIONS)

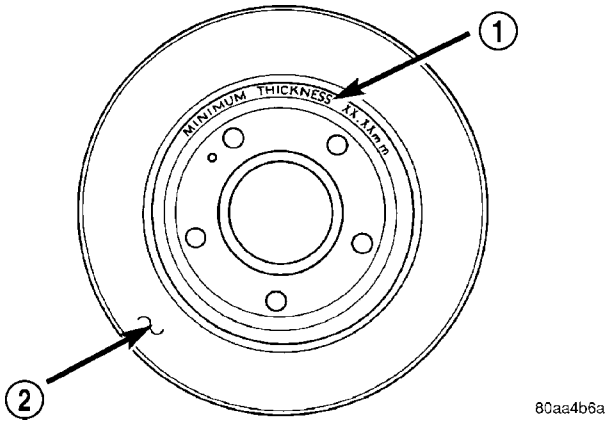

Fig. 120 Minimum Brake Rotor Thickness Markings (Typical)

1 - ROTOR MINIMUM THICKNESS MARKING
2 - ROTOR

ROTOR THICKNESS VARIATION

Thickness variation in a rotor's braking surface can result in pedal pulsation, chatter and surge. This can also be caused by excessive runout in the rotor or the hub.

Rotor thickness variation measurements should be made in conjunction with measuring runout. Measure thickness of the brake rotor at 12 equal points around the rotor braking surface with a micrometer at a radius approximately 25 mm (1 inch) from edge of rotor (Fig. 121). If thickness measurements vary beyond the specification listed in the specifaction table (Refer to 5 - BRAKES/HYDRAULIC/MECHANICAL/ROTOR - SPECIFICATIONS), the rotor should be refaced or replaced. (Refer to 5 - BRAKES/HYDRAULIC/MECHANICAL/ROTOR - STANDARD PROCEDURE)

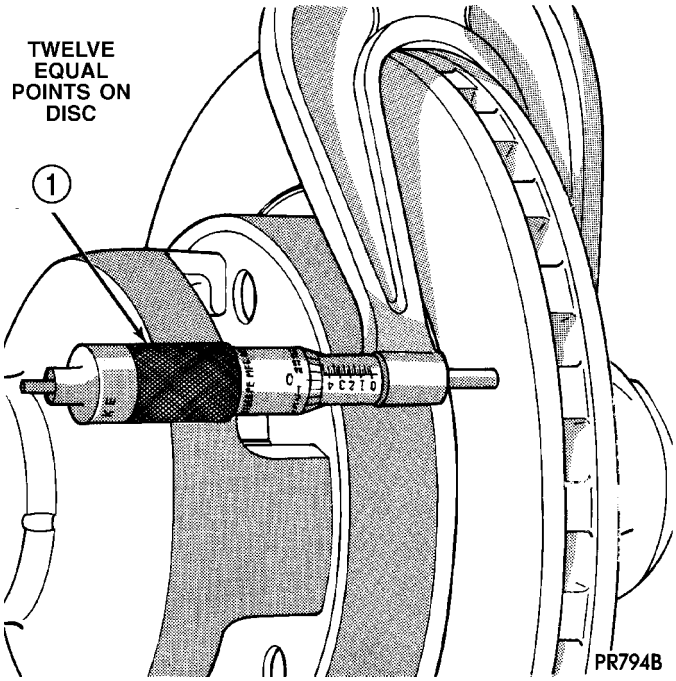

Fig. 121 Checking Rotor Thickness

1 - MICROMETER

ROTOR RUNOUT

On-vehicle rotor runout is the combination of the individual runout of the hub face and the runout of the rotor. (The hub and rotor runouts are separable). To measure rotor runout on the vehicle, first remove the tire and wheel assembly. Reinstall the wheel mounting nuts on the studs, tightening the rotor to the hub. Mount the Dial Indicator, Special Tool C-3339, with Mounting Adaptor, Special Tool SP-1910 on steering arm. The dial indicator plunger should contact braking surface of rotor approximately 25 mm (1 inch) from edge of rotor (Fig. 122). Check lateral runout on both sides of the rotor, marking the low and high spots on both. Runout limits can be found in the specification table in this section. (Refer to 5 - BRAKES/HYDRAULIC/MECHANICAL/ROTOR - SPECIFICATIONS)

If runout is in excess of the specification, check the lateral runout of the hub face. Before removing the rotor from the hub, place a chalk mark across both the rotor and the one wheel stud closest to where the high runout measurement was taken. This way, the original mounting spot of the rotor on the hub is indexed (Fig. 123).

Remove the rotor from the hub.

ROTOR (Continued)

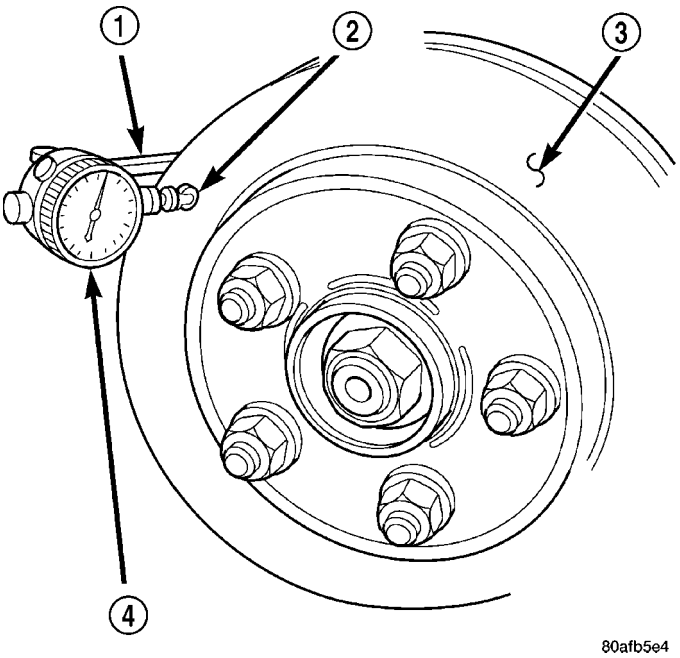

Fig. 122 Checking Rotor Runout

1 - SPECIAL TOOL SP-1910
2 - 25mm FROM EDGE
3 - DISC SURFACE
4 - SPECIAL TOOL C-3339

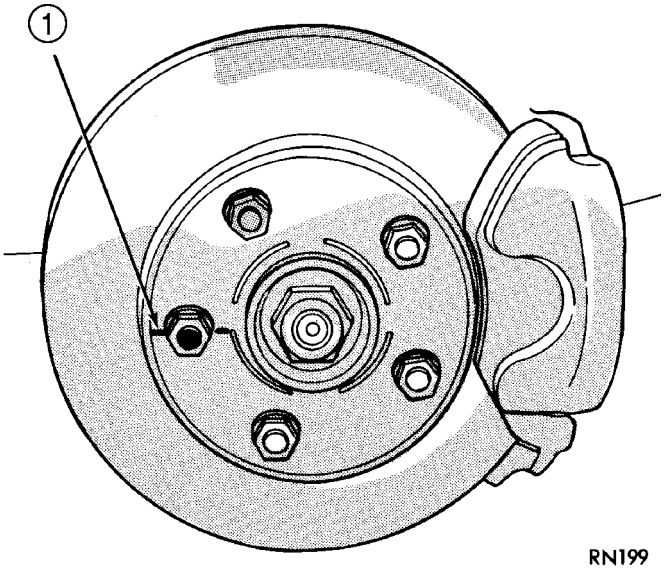

Fig. 123 Marking Rotor and Wheel Stud

1 - CHALK MARK

NOTE: Clean the hub face surface before checking runout. This provides a clean surface to get an accurate indicator reading.

Mount Dial Indicator, Special Tool C-3339, and Mounting Adaptor, Special Tool SP-1910, to the steering knuckle. Position the indicator stem so it contacts the hub face near the outer diameter. Care must be taken to position stem outside of the stud circle, but inside of the chamfer on the hub rim (Fig. 124).

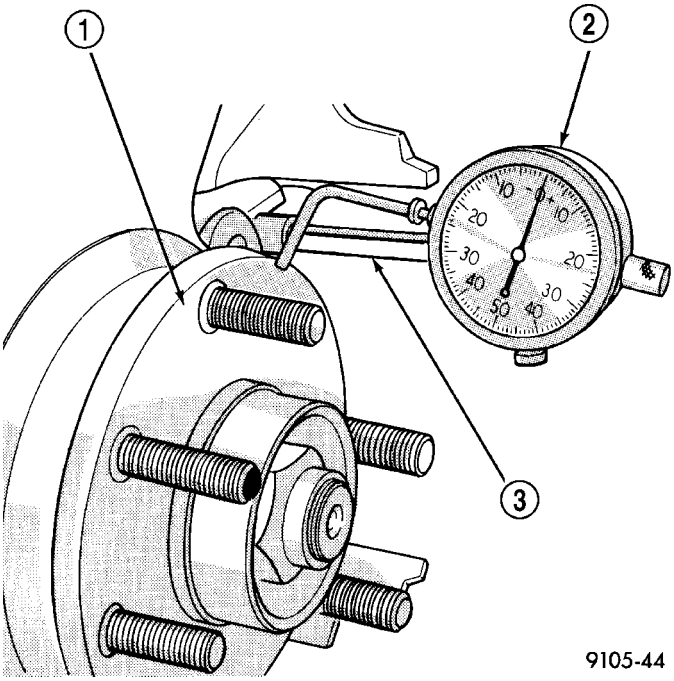

Fig. 124 Checking Hub Runout

1 - HUB SURFACE
2 - SPECIAL TOOL C-3339
3 - SPECIAL TOOL SP-1910

Hub runout should not exceed 0.08 mm (0.003 inch). If runout exceeds this specification, the hub must be replaced. For front hub removal, (Refer to 2 - SUSPENSION/FRONT/KNUCKLE - REMOVAL). For rear hub removal, (Refer to 2 - SUSPENSION/REAR/HUB / BEARING - REMOVAL).

If the hub runout does not exceed this specification, install the rotor back on the hub, aligning the chalk marks on the rotor with a wheel mounting stud, two studs apart from the original stud (Fig. 125). Tighten nuts in the proper sequence and torque to specifications.

Recheck brake rotor runout to see if the runout is now within specifications. (Refer to 5 - BRAKES/HYDRAULIC/MECHANICAL/ROTOR - SPECIFICATIONS)

If runout is not within specifications, reface or replace the brake rotor. (Refer to 5 - BRAKES/HYDRAULIC/MECHANICAL/ROTOR - STANDARD PROCEDURE)

ROTOR (Continued)

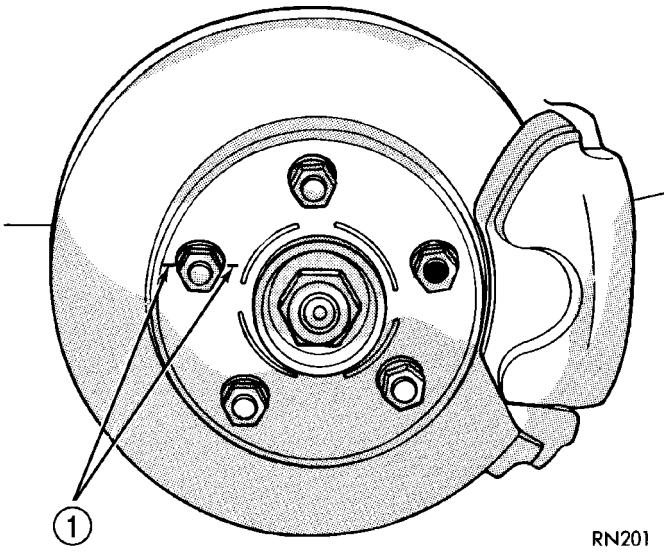

Fig. 125 Index Rotor And Wheel Stud

1 - CHALK MARK

STANDARD PROCEDURE - BRAKE ROTOR MACHINING

NOTE: Refacing the rotor is not required each time the brake pads are replaced, only when the need is foreseen.

Any servicing of the rotor requires extreme care to maintain the rotor within service tolerances to ensure proper brake action.

If the rotor surface is deeply scored or warped, or there is a complaint of brake roughness or brake pedal pulsation, the rotor should be refaced using a hub-mounted on-car brake lathe (Fig. 126), or replaced.

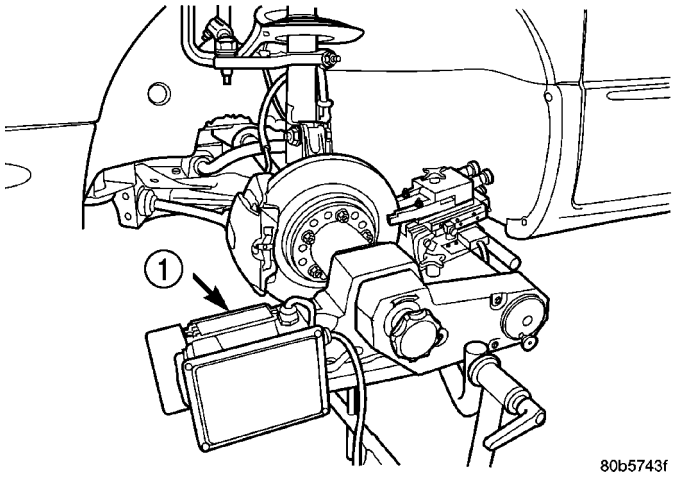

Fig. 126 On-Car Brake Lathe

1 - ON-CAR BRAKE LATHE

The use of a hub-mounted on-car brake lathe is highly recommended to eliminate the possibility of excessive runout. It trues the brake rotor to the vehicle's hub and bearing.

NOTE: All rotors have markings for minimum allowable thickness cast on an un-machined surface of the rotor (Fig. 127) or stamped into the hat section. Minimum thickness specifications can also be found in the specification table in this section. (Refer to 5 - BRAKES/HYDRAULIC/MECHANICAL/ ROTOR - SPECIFICATIONS)

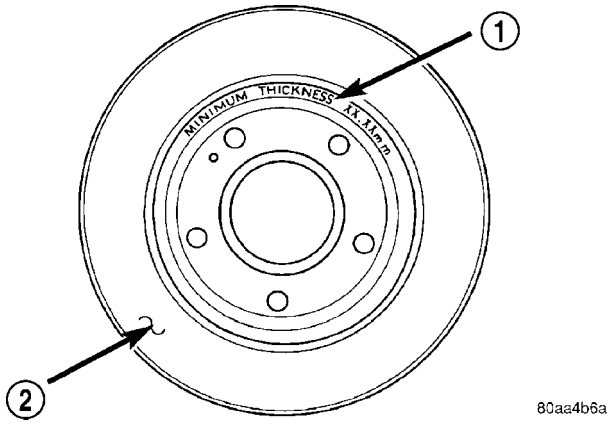

Fig. 127 Minimum Brake Rotor Thickness (Typical)

1 - ROTOR MINIMUM THICKNESS MARKING
2 - ROTOR

Minimum allowable thickness is the minimum thickness which the brake rotor machined surface may be cut to.

CAUTION: Do not machine the rotor if it will cause the rotor to fall below minimum thickness.

Before lathe installation, verify the brake rotor face and the hub adapters are free of any chips, rust, or contamination.

When mounting and using the brake lathe, strict attention to the brake lathe manufacturer's operating instructions is required.

Machine both sides of the brake rotor at the same time. Cutting both sides at the same time minimizes the possibility of a tapered or uneven cut.

When refacing a rotor, the required TIR (Total Indicator Reading) and thickness variation limits MUST BE MAINTAINED. Extreme care in the operation of rotor turning equipment is required. Specifications for brake rotor machining can be found in this sections specification table. (Refer to 5 - BRAKES/HYDRAULIC/MECHANICAL/ROTOR - SPECIFICATIONS)

ROTOR (Continued)

REMOVAL

REMOVAL - FRONT BRAKE ROTOR

NOTE: Before proceeding, (Refer to 5 - BRAKES - WARNING) (Refer to 5 - BRAKES - CAUTION).

(1) Raise the vehicle. (Refer to LUBRICATION & MAINTENANCE/HOISTING - STANDARD PROCEDURE)

(2) Remove the front tire and wheel assembly.

(3) Slide the caliper outward in an effort to retract the caliper piston into its bore.

(4) Remove the two bolts securing disc brake caliper adapter to the steering knuckle (Fig. 128).

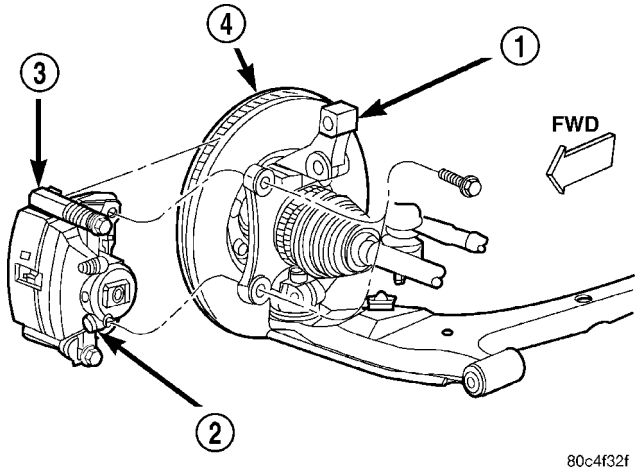

Fig. 128 Caliper/Adapter Mounting

1 - STEERING KNUCKLE
2 - DISC BRAKE CALIPER
3 - DISC BRAKE CALIPER ADAPTER
4 - BRAKE ROTOR

(5) Remove the disc brake caliper and adapter from the knuckle as an assembly. Hang the assembly out of the way using wire or a bungee cord. Use care not to overextend the brake hose when doing this.

(6) Remove the clips retaining the brake rotor to the wheel studs.

(7) Remove the brake rotor.

REMOVAL - REAR BRAKE ROTOR

NOTE: Before proceeding, (Refer to 5 - BRAKES - WARNING) (Refer to 5 - BRAKES - CAUTION).

(1) Raise the vehicle. (Refer to LUBRICATION & MAINTENANCE/HOISTING - STANDARD PROCEDURE)

(2) Remove the rear tire and wheel assembly.

(3) Remove the rear disc brake caliper and shoes from the brake rotor and store out of the way. (Refer to 5 - BRAKES/HYDRAULIC/MECHANICAL/BRAKE PADS/SHOES - REMOVAL)

(4) Remove any clips retaining the brake rotor (Fig. 21).

(5) Remove the brake rotor by pulling it straight off the wheel mounting studs.

INSTALLATION

INSTALLATION - FRONT BRAKE ROTOR

CAUTION: When installing new brake components, be sure to use correct parts. Parts designed for BR4 Performance Brake System must not be mixed with other brake systems. These parts, similar in appearance, can be easily identified (Fig. 118). (Refer to 5 - BRAKES/HYDRAULIC/MECHANICAL/ROTOR - DESCRIPTION)

NOTE: Inspect disc brake shoes before installation. (Refer to 5 - BRAKES/HYDRAULIC/MECHANICAL/BRAKE PADS/SHOES - INSPECTION)

(1) Install the brake rotor over the studs on the hub.

(2) Install the disc brake caliper and adapter assembly over the brake rotor.

(3) Install the mounting bolts securing the caliper adapter to the steering knuckle (Fig. 128). Tighten the bolts to a torque of 104 N·m (77 ft. lbs.).

(4) Install the tire and wheel assembly. Tighten the wheel mounting nuts to a torque of 135 N·m (100 ft. lbs.).

(5) Lower the vehicle.

(6) Pump the brake pedal several times before moving the vehicle to set the shoes to the brake rotor.

(7) Road test the vehicle and make several stops to seat the brake shoes to the rotor.

INSTALLATION - REAR BRAKE ROTOR

CAUTION: When installing new brake components, be sure to use correct parts. Parts designed for BR4 Performance Brake System must not be mixed with other brake systems. These parts, similar in appearance, can be easily identified (Fig. 119). (Refer to 5 - BRAKES/HYDRAULIC/MECHANICAL/ROTOR - DESCRIPTION)

NOTE: Inspect disc brake shoes and parking brake shoes before installation. (Refer to 5 - BRAKES/HYDRAULIC/MECHANICAL/BRAKE PADS/SHOES - INSPECTION)

(1) Install the rear brake rotor over the wheel mounting studs and onto the hub (Fig. 21).

ROTOR (Continued)

(2) Install rear disc brake caliper and shoes. (Refer to 5 - BRAKES/HYDRAULIC/MECHANICAL/ BRAKE PADS/SHOES - INSTALLATION)

(3) Install the tire and wheel assembly. Tighten the wheel mounting nuts to a torque of 135 N·m (100 ft. lbs.).

(4) Adjust the parking brake shoes as necessary. (Refer to 5 - BRAKES/PARKING BRAKE/SHOES - ADJUSTMENTS)

(5) Lower the vehicle.

(6) Pump the brake pedal before moving the vehicle to set the brake shoes to the brake rotor.

SPECIFICATIONS

BRAKE ROTOR LIMITS/SPECIFICATIONS

NOTE: When refacing a rotor, the required TIR (Total Indicator Reading) and thickness variation limits MUST BE MAINTAINED.

BRB/BRK/BRT SALES CODE

Braking Rotor	Rotor Thickness	Minimum Rotor Thickness	Rotor Thickness Variation	Rotor Runout*

SUPPORT PLATE - DRUM BRAKES

REMOVAL

NOTE: Before proceeding, (Refer to 5 - BRAKES - WARNING) (Refer to 5 - BRAKES - CAUTION).

(1) Using a brake pedal holding tool as shown (Fig. 129), depress the brake pedal past its first one inch of travel and hold it in this position. This will isolate the master cylinder from the brake hydraulic system and will not allow the brake fluid to drain out of the master cylinder reservoir.

(2) Raise the vehicle. (Refer to LUBRICATION & MAINTENANCE/HOISTING - STANDARD PROCEDURE)

(3) Remove the rear tire and wheel assembly.

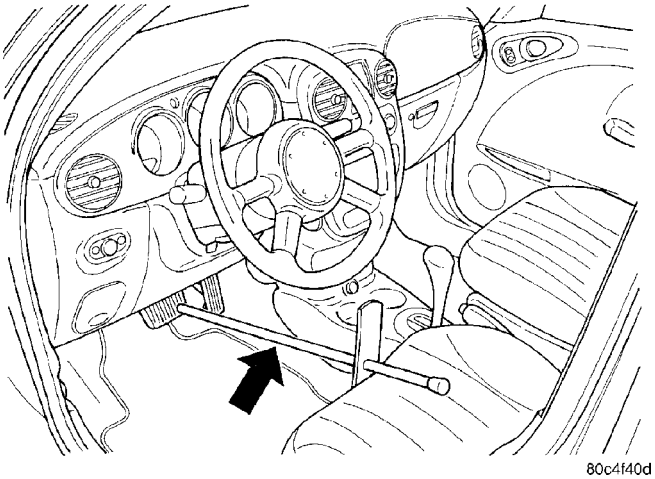

Fig. 129 Brake Pedal Holding Tool

(4) If equipped with ABS, remove the bolt attaching the wheel speed sensor to the support plate (Fig. 130), then carefully remove the sensor head.

SUPPORT PLATE - DRUM BRAKES (Continued)

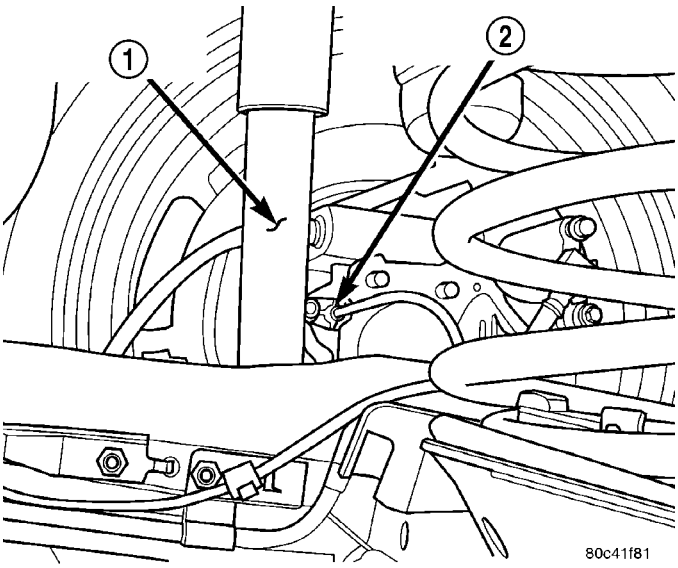

Fig. 130 Right Rear Wheel Speed Sensor

1 - SHOCK ABSORBER
2 - RIGHT REAR WHEEL SPEED SENSOR

(5) Disconnect the rear brake tube from the wheel cylinder (Fig. 131).

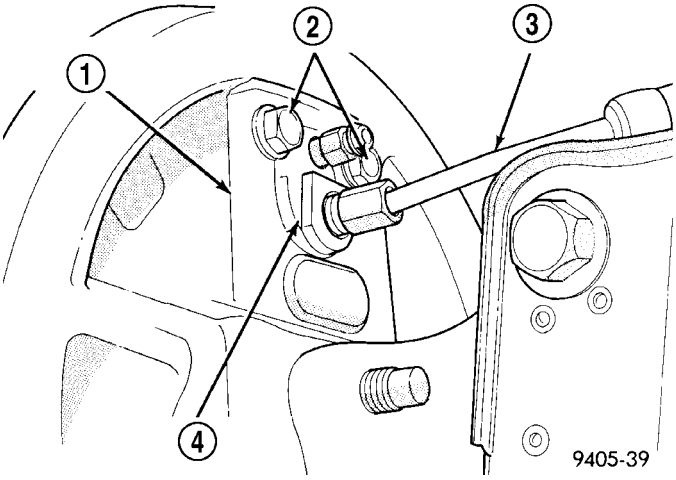

Fig. 131 Wheel Cylinder Mounting

1 - BRAKE SUPPORT PLATE
2 - WHEEL CYLINDER MOUNTING BOLTS
3 - REAR BRAKE TUBE
4 - WHEEL CYLINDER ASSEMBLY

(6) Remove the rear brake drum (Fig. 132). (Refer to 5 - BRAKES/HYDRAULIC/MECHANICAL/DRUM - REMOVAL)

(7) Remove the dust cap from the rear hub and bearing (Fig. 132).

(8) Remove the nut holding the rear hub and bearing to the spindle (Fig. 132). Remove the hub and bearing from the spindle.

(9) Remove the rear brake shoes from the brake support plate. (Refer to 5 - BRAKES/HYDRAULIC/MECHANICAL/BRAKE PADS/SHOES - REMOVAL)

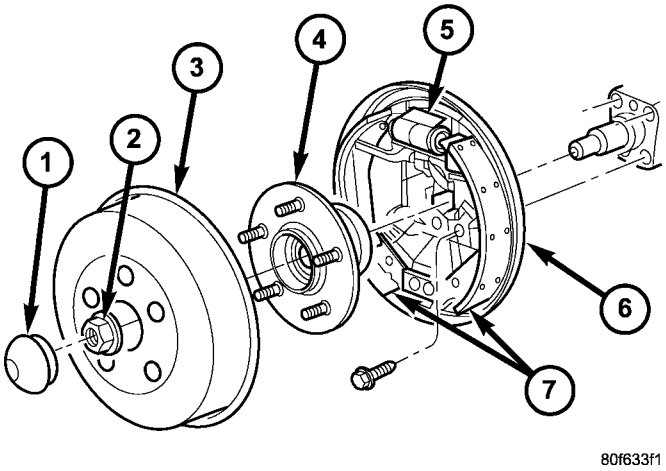

Fig. 132 Drum Brakes

1 - DUST CAP
2 - NUT
3 - DRUM
4 - HUB AND BEARING
5 - WHEEL CYLINDER
6 - SUPPORT PLATE
7 - BRAKE SHOES

(10) If not previously removed, remove the parking brake actuator lever from the parking brake cable.

(11) Position a ½ inch wrench over the retainer fingers on the end of the parking brake cable (Fig. 133). Compress the cable housing retaining fingers with the wrench, then pull the cable housing out of the support plate. Remove the wrench as the parking brake cable retainer is freed from the mounting hole in the brake support plate.

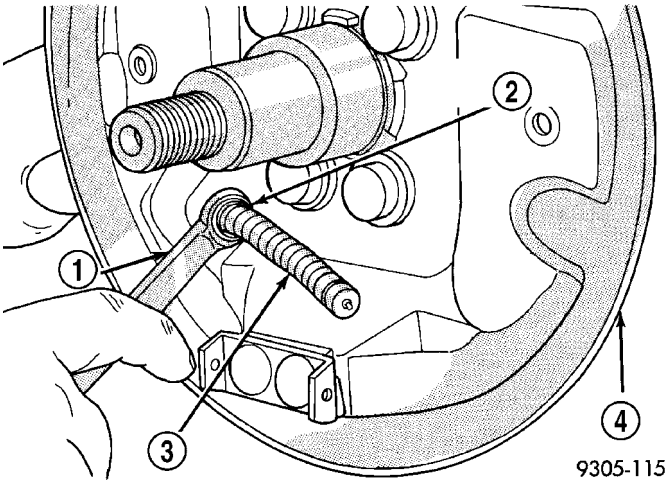

Fig. 133 Removing Park Brake Cable From Support Plate

1 - WRENCH
2 - CABLE HOUSING RETAINER
3 - PARK BRAKE CABLE
4 - SUPPORT PLATE

SUPPORT PLATE - DRUM BRAKES (Continued)

(12) Remove the four brake support plate mounting bolts and washers. Separate the brake support plate from the spindle.

(13) Remove the brake wheel cylinder attaching bolts (Fig. 131).

(14) Remove the brake wheel cylinder from the brake support plate.

INSTALLATION

NOTE: When installing wheel cylinder on brake support plate, be sure it is positioned squarely (horizontal) to the brake support plate.

(1) Install the wheel cylinder onto brake support plate (Fig. 131). Install and tighten the mounting bolts to a torque of 13 N·m (115 in. lbs.).

NOTE: When performing the following step, use new mounting bolts or clean and apply Mopar® Stud & Bearing Mount Adhesive or equivalent to the original mounting bolt threads before reuse.

(2) Install the brake support plate and seal on spindle. Tighten the support plate mounting bolts to a torque of 95 N·m (70 ft. lbs.).

(3) Insert the parking brake cable into its mounting hole in the brake support plate. Push the cable housing in until the retainer's fingers lock into place.

(4) Hand start the brake tube nut to the wheel cylinder (Fig. 131). Tighten the tube nut to a torque of 17 N·m (145 in. lbs.).

(5) Non-ABS equipped vehicle only – Attach the parking brake cable to the parking brake actuator.

(6) Install the rear brake shoe assemblies on the brake support plate. (Refer to 5 - BRAKES/HYDRAULIC/MECHANICAL/BRAKE PADS/SHOES - INSTALLATION)

(7) Install the rear hub and bearing assembly on the spindle. Install a NEW hub and bearing retaining nut (Fig. 132). Tighten the retaining nut to a torque of 217 N·m (160 ft. lbs.). Install dust cap.

(8) If equipped with ABS, Install the wheel speed sensor head into the rear of the support plate (Fig. 130). Install and tighten the sensor mounting bolt to a torque of 12 N·m (105 in. lbs.).

(9) Adjust the brake shoes to the drum diameter using a brake shoe gauge. (Refer to 5 - BRAKES/HYDRAULIC/MECHANICAL/BRAKE PADS/SHOES - ADJUSTMENT)

(10) Install the brake drum (Fig. 132).

(11) Install the wheel and tire assembly. Tighten the wheel mounting nuts to a torque of 135 N·m (100 ft. lbs.).

(12) Lower the vehicle.

(13) Remove the brake pedal holding tool.

(14) Bleed the affected wheel cylinder as necessary. (Refer to 5 - BRAKES - STANDARD PROCEDURE)

(15) Road test the vehicle to ensure proper brake operation.

WHEEL CYLINDER - DRUM BRAKE

REMOVAL

NOTE: Before proceeding, (Refer to 5 - BRAKES - WARNING) (Refer to 5 - BRAKES - CAUTION).

(1) Using a brake pedal holder, depress the brake pedal past its first one inch of travel and hold it in this position (Fig. 129). This will isolate the master cylinder from the brake hydraulic system and will not allow the brake fluid to drain out of the master cylinder reservoir.

(2) Raise and support the vehicle. (Refer to LUBRICATION & MAINTENANCE/HOISTING - STANDARD PROCEDURE)

(3) Remove the rear tire and wheel assembly.

(4) Disconnect the rear brake tube from the wheel cylinder (Fig. 131).

(5) Remove the brake drum. (Refer to 5 - BRAKES/HYDRAULIC/MECHANICAL/DRUM - REMOVAL)

(6) Remove the brake shoes from the brake support plate. (Refer to 5 - BRAKES/HYDRAULIC/MECHANICAL/BRAKE PADS/SHOES - REMOVAL)

NOTE: If the brake shoes are wet with grease or brake fluid, replace them.

(7) Remove the brake wheel cylinder mounting bolts (Fig. 131).

(8) Remove the brake wheel cylinder from the brake support plate.

(9) If applied, remove old sealer from mounting surfaces.

INSPECTION

With the brake drums removed, inspect the wheel cylinder boots for evidence of a brake fluid leak. Visually check the boots for cuts, tears, or heat cracks. If any of these conditions exist, the wheel cylinders should be completely cleaned, inspected and new parts installed.

If a wheel cylinder is leaking and the brake lining material is saturated with brake fluid, the brake shoes must be replaced.

WHEEL CYLINDER - DRUM BRAKE (Continued)

INSTALLATION

NOTE: When installing wheel cylinder on brake support plate, be sure it is positioned squarely (horizontal) to the brake assembly.

(1) Install the wheel cylinder onto the brake support plate (Fig. 131). Install and tighten the mounting bolts to a torque of 13 N·m (115 in. lbs.).

(2) Hand start the rear brake tube nut to the wheel cylinder. Tighten the tube nut to a torque of 17 N·m (145 in. lbs.).

(3) Install the rear brake shoes on the brake support plate. (Refer to 5 - BRAKES/HYDRAULIC/MECHANICAL/BRAKE PADS/SHOES - INSTALLATION)

(4) Adjust the rear brakes. (Refer to 5 - BRAKES/HYDRAULIC/MECHANICAL/BRAKE PADS/SHOES - ADJUSTMENTS)

(5) Install the brake drum onto the rear hub. (Refer to 5 - BRAKES/HYDRAULIC/MECHANICAL/DRUM - INSTALLATION)

(6) Install the tire and wheel assembly. Progressively tighten the wheel mounting nuts to a torque of 135 N·m (100 ft. lbs.).

(7) Lower the vehicle.

(8) Remove the brake pedal holder.

(9) Bleed the wheel cylinder as necessary. (Refer to 5 - BRAKES - STANDARD PROCEDURE)

(10) Road test the vehicle to make sure the brakes operate correctly.

PARKING BRAKE

DESCRIPTION

The parking brakes consist of the following components:

- Hand-operated park brake lever - automatic-adjusting
- Parking brake cables (2)
- Actuation levers and struts
- Duo-servo parking brake assembly (rear disc only)

All vehicles are equipped with a center-mounted, hand-operated parking brake lever mounted between the front seats (Fig. 134). This lever is an automatic-adjusting type that continuously applies minimal tension to the parking brake cables to keep them in adjustment at all times.

The parking brake lever has a short output cable with an equalizer bracket attached to it that connects to the parking brake cables (Fig. 134). The output cable can only be serviced as part of the parking brake lever.

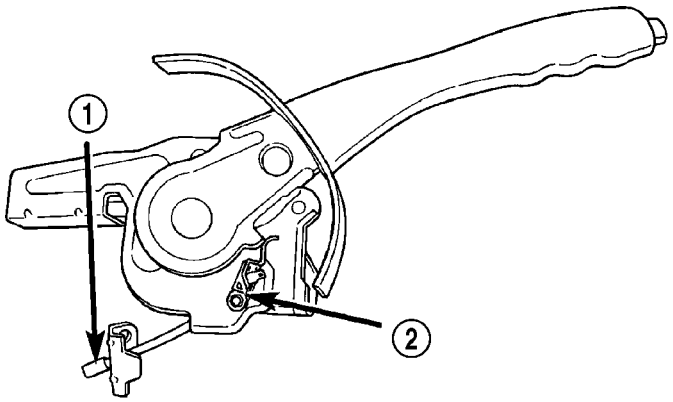

Fig. 134 Parking Brake Lever

1 - OUTPUT CABLE
2 - SWITCH

There is an individual parking brake cable for each rear wheel that joins a parking brake cable equalizer, attached to the parking brake lever, to the rear parking brakes. The parking brake cables are made of flexible steel cable. Both drum rear brakes and disc rear brakes use the same parking brake cable configuration, but the cables are different.

On vehicles equipped with rear drum brakes, the rear wheel service brakes also act as the vehicle's parking brakes. The rear drum brake shoes, when acting as parking brakes, are mechanically operated using an internal actuating lever and strut connected to the flexible steel parking brake cable.

The parking brakes on vehicles equipped with rear disc brakes consist of a small duo-servo brake assembly mounted to the disc brake caliper adapter (Fig. 135). The hat (center) section of the rear brake rotor serves as the braking surface (drum) for the parking brakes (Fig. 136). This parking brake application uses the same operating cable configuration as the drum brake equipped vehicles, but different cables.

OPERATION

When the parking brake is applied, the equalizer bracket on the lever output cable pulls on both parking brake cables, thus applying the brake shoes (rear drum brakes) or parking brake shoes (rear disc brakes).

The brake shoes are mechanically operated by an internal lever and strut connected to the parking brake cables.

The parking brake lever automatic-adjusting feature continuously applies minimal tension to the parking brake cables to keep them in adjustment at all times. Therefore, the parking brake cable system does not require adjustment. Proper parking brake system adjustment is obtained by proper drum brake or drum-in-hat brake shoe adjustment. When service is needed, the lever auto-adjust mechanism must be reloaded and locked out before service can be performed.

PARKING BRAKE (Continued)

STANDARD PROCEDURE - PARKING BRAKE AUTOMATIC ADJUSTER LOCKOUT

WARNING: THE AUTOMATIC ADJUSTING FEATURE OF THIS PARKING BRAKE LEVER CONTAINS A CLOCKSPRING LOADED TO APPROXIMATELY 19 POUNDS. DO NOT RELEASE THE AUTOMATIC ADJUSTER LOCKOUT DEVICE UNLESS THE REAR PARKING BRAKE CABLES AND EQUALIZER ARE CONNECTED TO THE LEVER OUTPUT CABLE. KEEP HANDS OUT OF AUTOMATIC ADJUSTER SECTOR AND PAWL AREA. FAILURE TO OBSERVE CAUTION IN HANDLING THIS MECHANISM COULD LEAD TO SERIOUS INJURY.

WARNING: WHEN REPAIRS TO THE PARKING BRAKE LEVER OR CABLES ARE REQUIRED, THE AUTOMATIC ADJUSTER MUST BE LOADED AND LOCKED OUT TO AVOID POSSIBLE INJURY.

LOCKING AUTOMATIC ADJUSTER OUT

(1) Block the tire and wheels so the vehicle does not move once the vehicle parking brake lever is released.

(2) Remove the transmission shift knob as necessary.

(3) Place parking brake lever in released (full OFF) position.

(4) Remove the screws attaching the center console.

(5) Remove rear window switch panel from the console.

(6) Working through switch opening, grasp a parking brake cable or equalizer and pull back approximately 25.4 mm (1 in.)

(7) While holding the cable or equalizer, pull the parking brake handle to it's full upright position.

(8) Remove center console.

(9) Grasp the parking brake lever output cable by hand and pull upward. Continue pulling cable until an appropriate pin punch (drill bit or locking pin) can be inserted sufficiently through hole in left side of the lever mounting bracket (Fig. 137). This will lock the parking brake automatic adjustment mechanism in place and take tension off the parking brake cables. Slowly release the output cable. There should now be slack in the cables.

PARKING BRAKE (Continued)

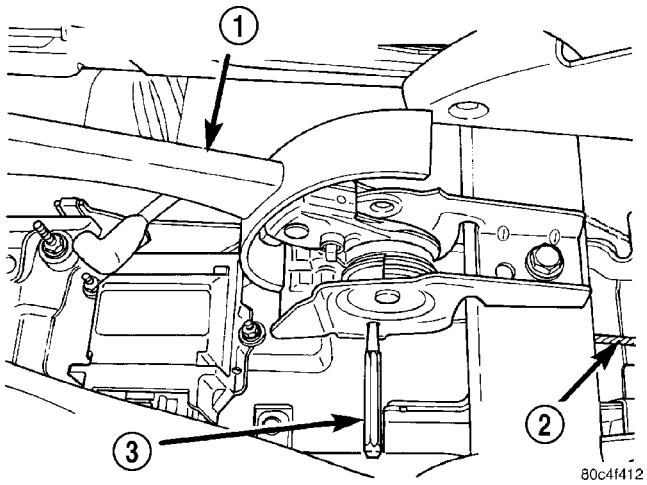

Fig. 137 Pin Punch Installed

1 - PARKING BRAKE LEVER
2 - OUTPUT CABLE
3 - PIN PUNCH

UNLOCKING AUTOMATIC ADJUSTER (UNLOADING)

(1) Be sure the rear parking brake cables are both properly installed in the equalizer.

(2) Raise parking brake handle to the full upright position.

(3) Keeping your hands clear of the automatic adjuster sector and pawl area, firmly grasp the parking brake lever pin punch (drill bit or locking pin if a new mechanism has been installed) (Fig. 137), then quickly remove it from the parking brake lever mechanism. This will allow the park brake lever mechanism to automatically adjust the parking brake cables.

(4) Install the center console and its mounting screws.

(5) Cycle the parking brake lever once to position the parking brake cables, then return the parking brake lever to its released (full OFF) position.

(6) Check the rear wheels of the vehicle. They should rotate freely without dragging with the lever in its released (full OFF) position.

(7) Install rear window switch panel.

(8) Remove the blocks from the tire and wheels.

CABLE - PARKING BRAKE

REMOVAL

WARNING: THE AUTOMATIC ADJUSTING FEATURE OF THIS PARKING BRAKE LEVER CONTAINS A CLOCK SPRING LOADED TO APPROXIMATELY 19 POUNDS. DO NOT RELEASE THE AUTOMATIC ADJUSTER LOCKOUT DEVICE UNLESS THE REAR PARKING BRAKE CABLES AND EQUALIZER ARE CONNECTED TO THE LEVER OUTPUT CABLE. KEEP HANDS OUT OF AUTOMATIC ADJUSTER SECTOR AND PAWL AREA. FAILURE TO OBSERVE CAUTION IN HANDLING THIS MECHANISM COULD LEAD TO SERIOUS INJURY.

WARNING: WHEN REPAIRS TO THE PARKING BRAKE LEVER OR CABLES ARE REQUIRED, THE AUTOMATIC ADJUSTER MUST BE LOADED AND LOCKED OUT TO AVOID POSSIBLE INJURY. THE LEVER ADJUSTMENT MECHANISM CAN BE LOADED AND LOCKED OUT AS OUTLINED IN THIS PROCEDURE.

WARNING: THE AIRBAG SYSTEM IS A COMPLEX ELECTROMECHANICAL UNIT. BEFORE ATTEMPTING TO SERVICE ANY COMPONENT NEAR THE OCCUPANT RESTRAINT CONTROLLER (ORC), FIRST DISCONNECT AND ISOLATE THE BATTERY NEGATIVE CABLE. ALLOW THE SYSTEM CAPACITOR TO DISCHARGE FOR TWO (2) MINUTES. FAILURE TO DO THIS COULD RESULT IN ACCIDENTAL AIRBAG DEPLOYMENT AND POSSIBLE PERSONAL INJURY.

NOTE: Before proceeding, (Refer to 5 - BRAKES - WARNING) (Refer to 5 - BRAKES - CAUTION).

NOTE: The procedure below applies to either of the two rear parking brake cables.

CABLE - PARKING BRAKE (Continued)

(1) Unclip the air cleaner cover (two clips) and move the cover aside.

(2) Disconnect and isolate the battery negative cable from its post on the battery.

(3) Block the tire and wheels so the vehicle does not move once the vehicle parking brake lever is released.

(4) Remove the transmission shift knob as necessary.

(5) Place parking brake lever in released (full OFF) position.

(6) Remove screws attaching center console.

(7) Remove rear window switch panel from console.

(8) Working through switch opening, grasp a parking brake cable or equalizer and pull back approximately 25.4 mm (1 in.)

(9) While holding the cable or equalizer, pull the parking brake handle to it's full upright position.

(10) Remove center console.

(11) Grasp the parking brake lever output cable by hand and pull upward. Continue pulling on the cable until an appropriate sized pin punch (drill bit or locking pin) can be inserted sufficiently through the hole in the left side of the lever mounting bracket (Fig. 138). This will lock the parking brake automatic adjustment mechanism in place and take tension off the parking brake cables. Slowly release the output cable. There should now be slack in the cables.

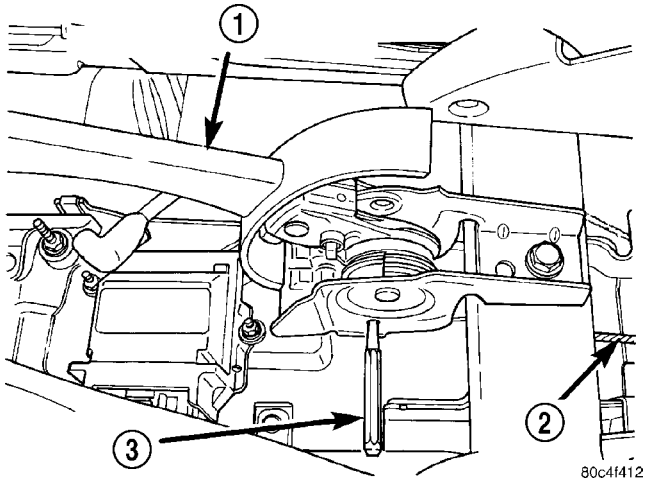

Fig. 138 Pin Punch Installed

1 - PARKING BRAKE LEVER
2 - OUTPUT CABLE
3 - PIN PUNCH

(12) Remove the rear parking brake cables from the parking brake cable equalizer (Fig. 139).

(13) Remove the rear seat cushion from the vehicle.

(14) Fold the rear carpeting forward to expose the parking brake cables at the end of the rear floor.

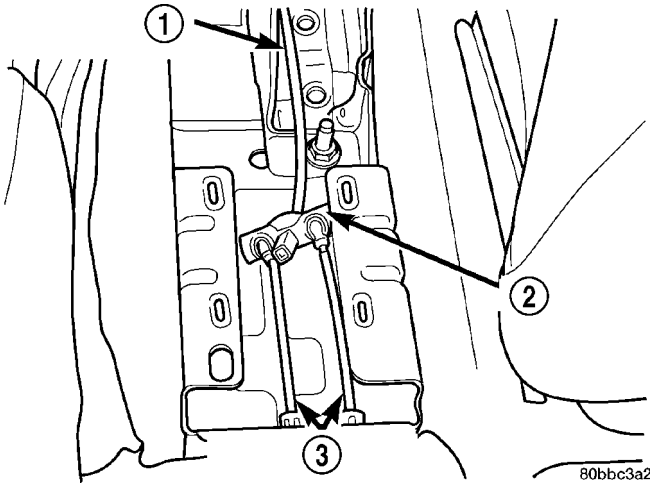

Fig. 139 Parking Brake Cables At Equalizer

1 - LEVER OUTPUT CABLE
2 - EQUALIZER
3 - REAR PARKING BRAKE CABLES

(15) Install the box end of a ½ inch wrench over the parking brake cable retainer (Fig. 140). Push the wrench onto the retainer until the retainer fingers are collapsed. From under the carpeting, grasp the parking brake cable housing and pull cable straight out of the bracket attached to the floor.

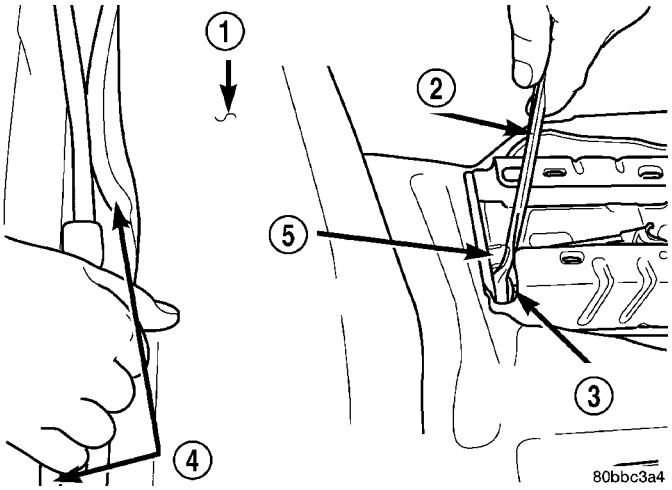

Fig. 140 Compressing Cable Retainer

1 - CARPET ROLLED FORWARD
2 - WRENCH
3 - RIGHT REAR CABLE
4 - REAR PARKING BRAKE CABLES
5 - LEFT REAR CABLE

(16) Raise the vehicle. (Refer to LUBRICATION & MAINTENANCE/HOISTING - STANDARD PROCEDURE)

(17) Remove the rear tire and wheel assembly from the vehicle.

(18) On vehicles equipped with rear drum brakes, remove the brake drum. (Refer to 5 - BRAKES/HYDRAULIC/MECHANICAL/DRUM - REMOVAL)

CABLE - PARKING BRAKE (Continued)

(19) On vehicles equipped with rear disc brakes:

• Remove the disc brake caliper guide pin bolts, then the caliper from the disc brake adapter (Fig. 141).

• Hang the caliper out of the way using a wire hanger or cord.

• Remove the brake rotor from the rear hub and bearing.

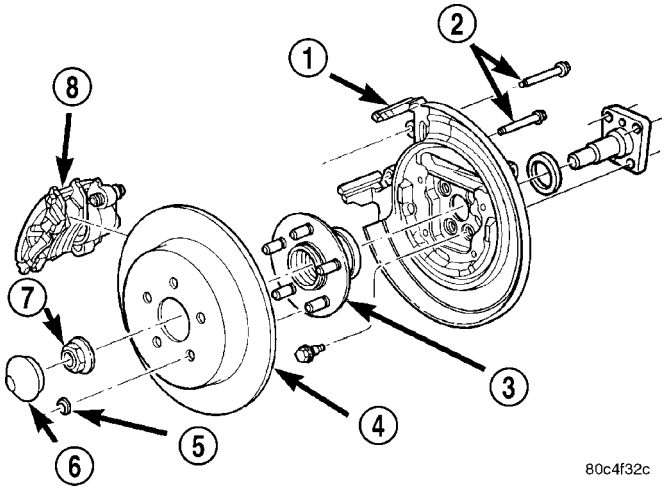

Fig. 141 Rear Disc Brakes

1 - DISC BRAKE ADAPTER
2 - GUIDE PIN BOLTS
3 - HUB AND BEARING
4 - BRAKE ROTOR
5 - RETAINER CLIP
6 - DUST CAP
7 - NUT
8 - DISC BRAKE CALIPER

(20) Remove the dust cap from the rear hub and bearing.

(21) Remove the hub and bearing retaining nut from the knuckle spindle, then remove the hub and bearing (Fig. 141).

(22) On vehicles equipped with rear disc brakes, remove the upper return spring, both shoe hold-down clips, then spread the rear parking brake shoes apart at the top enough to clear the shoe anchor and remove the parking brake shoes as an assembly from the disc brake adapter (Fig. 142).

(23) To remove the rear parking brake cable from the brake support plate on vehicles equipped with rear drum brakes:

• Remove the parking brake cable from the parking brake actuating lever (Fig. 143).

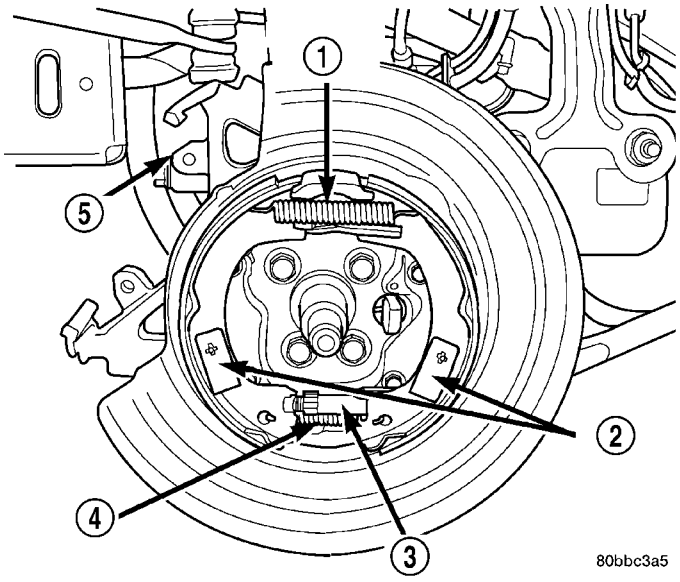

Fig. 142 Parking Brake Shoes

1 - UPPER RETURN SPRING
2 - SHOE HOLD DOWN CLIPS
3 - ADJUSTER
4 - LOWER REAR SPRING
5 - DISC BRAKE ADAPTER

CABLE - PARKING BRAKE (Continued)

• Remove the actuating spring between the brake shoe adjustment lever and the brake shoe (Fig. 144).

• Remove the parking brake cable from the rear brake support plate. The parking brake cable can be removed from brake support plate using a ½ inch box wrench to compress the locking fingers on the parking brake cable retainer (Fig. 145).

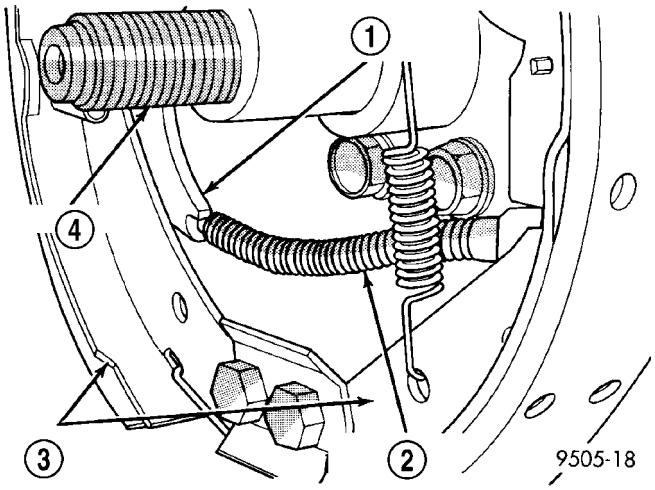

Fig. 143 Actuator Lever

4 - REAR SPINDLE

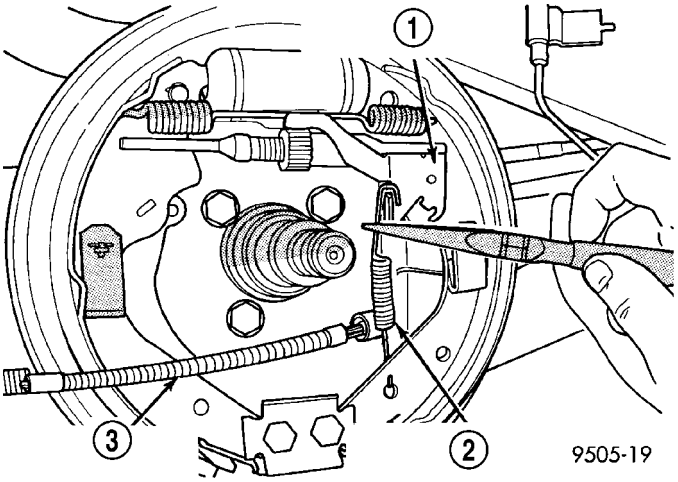

Fig. 144 Actuating Spring

1 - BRAKE SHOE ADJUSTMENT LEVER
2 - ADJUSTMENT LEVER ACTUATING SPRING
3 - PARK BRAKE CABLE

(24) To remove the rear parking brake cable from the disc brake adapter on vehicles equipped with rear disc brakes:

• Remove the parking brake actuating lever from the parking brake cable (Fig. 146).

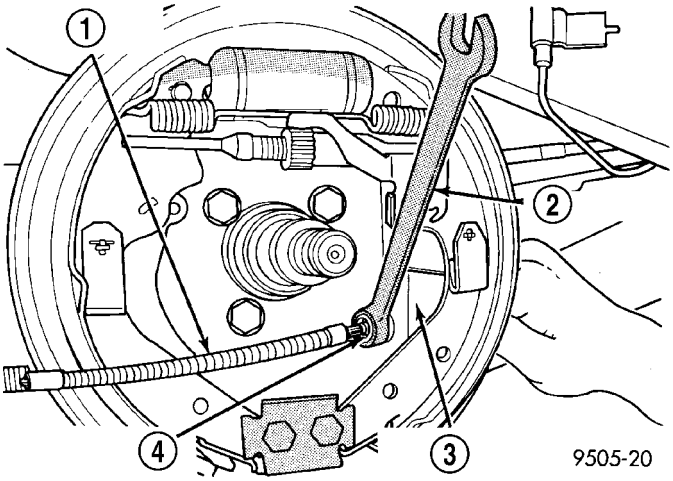

Fig. 145 Parking Brake Cable Removal

1 - PARK BRAKE CABLE
2 - 1/2'' WRENCH
3 - REAR BRAKE SUPPORT PLATE
4 - PARK BRAKE CABLE RETAINER

• Remove the parking brake cable from the rear disc brake adapter. The parking brake cable can be removed from the disc brake adapter using a ½ inch offset box wrench to compress the locking fingers on the parking brake cable retainer (Fig. 147).

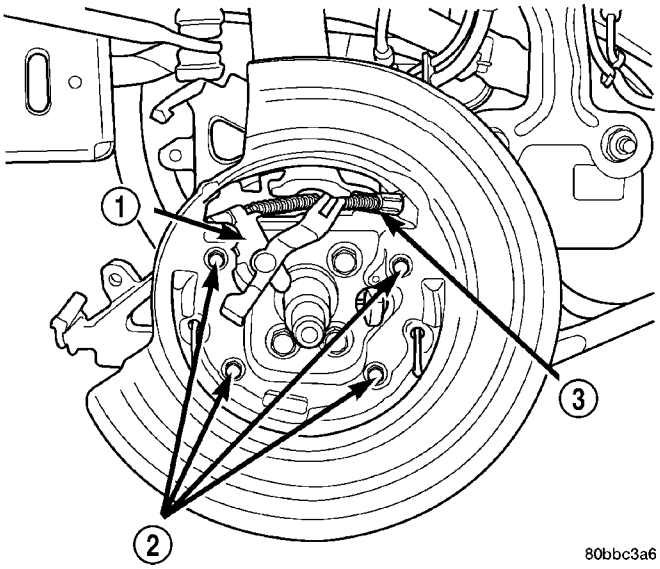

Fig. 146 Parking Brake Actuator Lever

1 - SHOE ACTUATOR LEVER

3 - REAR PARKING BRAKE CABLE

CABLE - PARKING BRAKE (Continued)

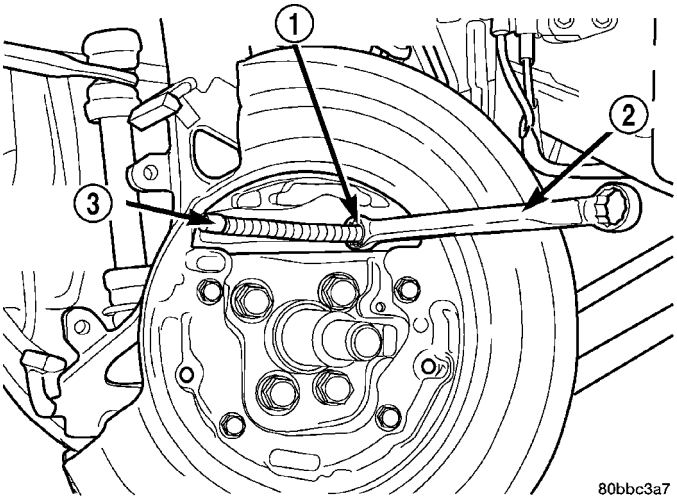

Fig. 147 Parking Brake Cable Removal

1 - CABLE RETAINER
2 - OFFSET BOX WRENCH
3 - PARKING BRAKE CABLE

(25) Remove the two fasteners securing the cable and routing brackets to the axle trailing arm (Fig. 148).

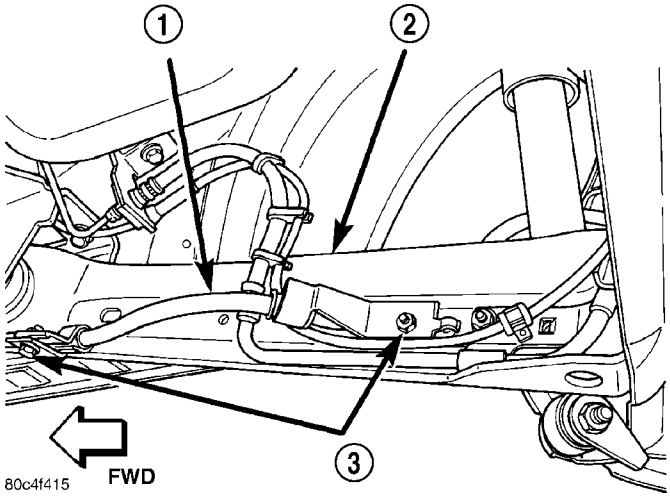

Fig. 148 Cable Routing Bracket Fasteners

1 - CABLE
2 - ARM
3 - FASTENERS

(26) Pull cable through hole in trailing arm.

(27) Remove the parking brake cable and sealing grommet from floor pan of the vehicle.

INSTALLATION

WARNING: THE AUTOMATIC ADJUSTING FEATURE OF THIS PARKING BRAKE LEVER CONTAINS A CLOCK SPRING LOADED TO APPROXIMATELY 19 POUNDS. DO NOT RELEASE THE AUTOMATIC ADJUSTER LOCKOUT DEVICE UNLESS THE REAR PARKING BRAKE CABLES AND EQUALIZER ARE CONNECTED TO THE LEVER OUTPUT CABLE. KEEP HANDS OUT OF AUTOMATIC ADJUSTER SECTOR AND PAWL AREA. FAILURE TO OBSERVE CAUTION IN HANDLING THIS MECHANISM COULD LEAD TO SERIOUS INJURY.

NOTE: The procedure below applies to either of the two rear parking brake cables.

(1) From underneath, push the parking brake cable through the hole in the floor pan of the vehicle making sure the cable sealing grommet is installed in the floor pan as far as possible to ensure a good seal.

(2) Guide the other end of the cable through the hole in the axle trailing arm.

(3) Align the cable routing brackets with their mounts on the trailing arm. Install the two fasteners securing the cable and routing brackets to the trailing arm (Fig. 148). Install and tighten the mounting bolts to a torque of 11 N·m (100 in. lbs.).

(4) Install the parking brake cable into the brake support plate or the rear disc brake adapter. Be sure the locking fingers on the cable retainer are expanded once the cable is pushed all the way into the support plate or brake adapter hole to ensure the cable is securely held in place.

(5) On vehicles equipped with rear drum brakes:

- Install the parking brake cable on the parking brake cable actuating lever (Fig. 143).
- Install the actuating spring to the brake shoe and the brake adjustment lever (Fig. 144).

(6) On vehicles equipped with rear disc brakes:

- Install the parking brake shoes actuator lever on the parking brake cable (Fig. 146).
- Install the parking brake shoe assemblies on the disc brake adapter (Fig. 142).

(7) Install the hub and bearing on the rear spindle. Install a new hub and bearing retaining nut. Tighten the retaining nut to a torque of 217 N·m (160 ft. lbs.).

(8) Install the hub and bearing dust cap.

(9) On drum brake equipped vehicles, install the rear brake drum.

(10) On vehicles equipped with rear disc brakes, install the brake rotor, then the disc brake caliper (Fig. 141). Install the two caliper guide pin bolts, then tighten them to a torque of 22 N·m (192 in. lbs.).

(11) Install the rear tire and wheel assembly. Tighten all wheel nuts to a torque of 135 N·m (100 ft. lbs.).

(12) Lower the vehicle.

(13) Ensure that the seal grommet on the cable that was installed from underneath is fully seated into the floor pan.

CABLE - PARKING BRAKE (Continued)

(14) Route the parking brake cable under the carpeting, up to parking brake cable retaining bracket on floor pan. Install the parking brake cable through the retaining bracket. Push the cable in until the locking fingers on the cable retainer lock the cable into place.

(15) Install the rear parking brake cables into the equalizer on the parking brake lever output cable (Fig. 139).

(16) Ensure that the parking brake cables are correctly installed on the equalizer and aligned with the cable track on the parking brake lever.

(17) Raise parking brake handle to full upright (applied) position.

(18) Keeping your hands clear of the automatic adjuster sector and pawl area, firmly grasp the parking brake lever pin punch (drill bit or locking pin if a new mechanism has been installed) (Fig. 138), then quickly remove it from the parking brake lever mechanism. This will allow the park brake lever mechanism to automatically adjust the parking brake cables.

(19) Install center console and mounting screws.

(20) Install rear window switch panel.

(21) Cycle the parking brake lever once to position the parking brake cables, then return the parking brake lever its released position.

(22) Check the rear wheels of the vehicle. They should rotate freely without dragging with the lever in its released position.

(23) Apply the parking brake.

(24) Remove the blocks from the tires and wheels.

(25) Reconnect the battery negative terminal.

(26) Reinstall the air cleaner cover (two clips).

LEVER - PARKING BRAKE

REMOVAL

WARNING: THE AUTOMATIC ADJUSTING FEATURE OF THIS PARKING BRAKE LEVER CONTAINS A CLOCK SPRING LOADED TO APPROXIMATELY 19 POUNDS. DO NOT RELEASE THE AUTOMATIC ADJUSTER LOCKOUT DEVICE UNLESS THE REAR PARKING BRAKE CABLES AND EQUALIZER ARE CONNECTED TO THE LEVER OUTPUT CABLE. KEEP HANDS OUT OF AUTOMATIC ADJUSTER SECTOR AND PAWL AREA. FAILURE TO OBSERVE CAUTION IN HANDLING THIS MECHANISM COULD LEAD TO SERIOUS INJURY.

WARNING: WHEN REPAIRS TO THE PARKING BRAKE LEVER OR CABLES ARE REQUIRED, THE AUTOMATIC ADJUSTER MUST BE LOADED AND LOCKED OUT TO AVOID POSSIBLE INJURY. THE LEVER ADJUSTMENT MECHANISM CAN BE LOADED AND LOCKED OUT AS OUTLINED IN THIS PROCEDURE.

WARNING: THE AIRBAG SYSTEM IS A COMPLEX ELECTROMECHANICAL UNIT. BEFORE ATTEMPTING TO SERVICE ANY COMPONENT NEAR THE OCCUPANT RESTRAINT CONTROLLER (ORC), FIRST DISCONNECT AND ISOLATE THE BATTERY NEGATIVE CABLE. ALLOW THE SYSTEM CAPACITOR TO DISCHARGE FOR TWO (2) MINUTES. FAILURE TO DO THIS COULD RESULT IN ACCIDENTAL AIRBAG DEPLOYMENT AND POSSIBLE PERSONAL INJURY.

(1) Unclip the air cleaner cover (two clips) and move the cover aside.

(2) Disconnect and isolate the battery negative cable from its post on the battery.

(3) Block the tire and wheels so the vehicle does not move once the vehicle parking brake lever is released.

(4) Remove the transmission shift knob as necessary.

(5) Place parking brake lever in released (full OFF) position.

(6) Remove screws attaching center console.

(7) Remove rear switch panel from center console.

(8) Working through switch opening, grasp a parking brake cable or equalizer and pull back approximately 25.4 mm (1 in.)

(9) While holding the cable or equalizer, pull the parking brake handle to it's full upright position.

(10) Remove center console.

(11) Grasp the parking brake lever outout cable by hand and pull upward. Continue pulling cable until an appropriate pin punch (drill bit or locking pin) can be inserted sufficiently through hole in left side of the lever mounting bracket (Fig. 149). This will lock the barking brake automatic adjustment mechanism in place and take tension off the parking brake cables. Slowly release the output cable. There should now be slack in the cables.

LEVER - PARKING BRAKE (Continued)

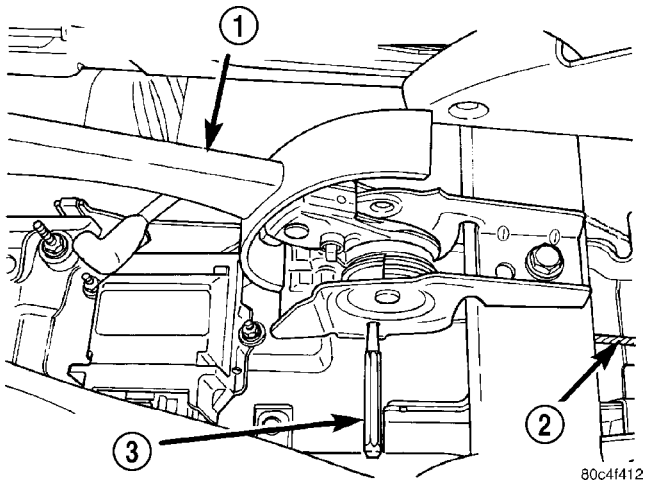

Fig. 149 Pin Punch Installed

1 - PARKING BRAKE LEVER
2 - OUTPUT CABLE
3 - PIN PUNCH

(12) Remove both rear parking brake cables from the parking brake cable equalizer (Fig. 150).

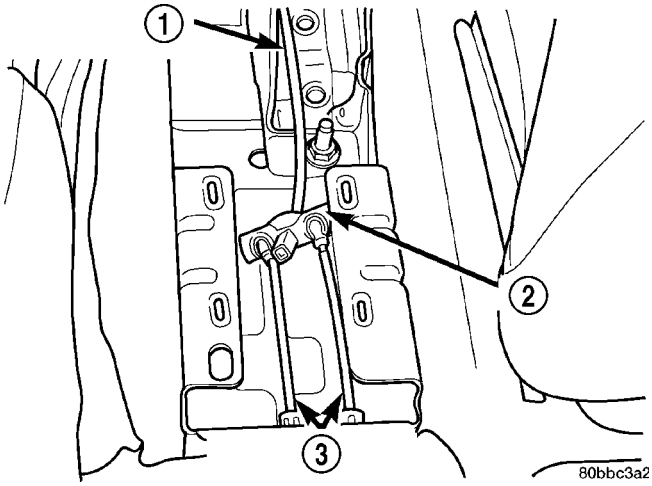

Fig. 150 Parking Brake Cables At Equalizer

1 - LEVER OUTPUT CABLE
2 - EQUALIZER
3 - REAR PARKING BRAKE CABLES

(13) Remove the wiring harness electrical connector from the parking brake warning switch on the right side of the parking brake lever.

(14) Remove the screw and the nut attaching the parking brake lever to the vehicle (Fig. 151).

(15) Remove the parking brake lever from the vehicle.

INSTALLATION

WARNING: THE AUTOMATIC ADJUSTING FEATURE OF THIS PARKING BRAKE LEVER CONTAINS A CLOCK SPRING LOADED TO APPROXIMATELY 19 POUNDS. DO NOT RELEASE THE AUTOMATIC ADJUSTER LOCKOUT DEVICE UNLESS THE REAR PARKING BRAKE CABLES AND EQUALIZER ARE CONNECTED TO THE LEVER OUTPUT CABLE. KEEP HANDS OUT OF AUTOMATIC ADJUSTER SECTOR AND PAWL AREA. FAILURE TO OBSERVE CAUTION IN HANDLING THIS MECHANISM COULD LEAD TO SERIOUS INJURY.

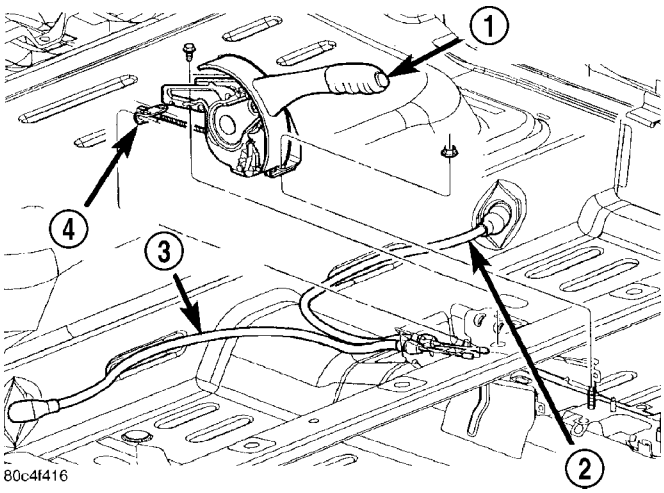

Fig. 151 Parking Brake Lever

1 - PARKING BRAKE LEVER
2 - LEFT CABLE
3 - RIGHT CABLE
4 - EQUALIZER

(1) Place the parking brake lever on the mounting studs on the vehicle floor. Install and tighten the screw and the nut to a torque of 28 N·m (250 in. lbs.) (Fig. 151).

(2) Connect the wiring harness electrical connector on the parking brake warning switch.

(3) Install both rear park brake cables into the equalizer on the parking brake lever output cable (Fig. 150).

(4) Ensure that the parking brake cables are correctly installed on the equalizer and aligned with the cable track on the parking brake lever.

(5) Raise parking brake handle to full upright (applied) position.

(6) Keeping your hands clear of the automatic adjuster sector and pawl area, firmly grasp the parking brake lever pin punch (drill bit or locking pin if a new mechanism has been installed) (Fig. 149), then quickly remove it from the parking brake lever mechanism. This will allow the park brake lever mechanism to automatically adjust the parking brake cables.

(7) Install center console and mounting screws.

(8) Install rear window switch panel.

(9) Cycle the parking brake lever once to position the parking brake cables, then return the parking brake lever its released (full OFF) position.

LEVER - PARKING BRAKE (Continued)

(10) Check the rear wheels of the vehicle. They should rotate freely without dragging with the lever in its released (full OFF) position.
(11) Apply the parking brake.
(12) Remove the blocks from the tires and wheels.
(13) Reconnect the battery negative terminal.
(14) Reinstall the air cleaner cover (two clips).

SHOES - PARKING BRAKE

REMOVAL

NOTE: Before proceeding, (Refer to 5 - BRAKES - WARNING) (Refer to 5 - BRAKES - CAUTION).

(1) Raise the vehicle. (Refer to LUBRICATION & MAINTENANCE/HOISTING - STANDARD PROCEDURE)
(2) Remove the rear tire and wheel assembly.
(3) Remove the rear disc brake caliper assembly from the brake rotor and store it out of the way. (Refer to 5 - BRAKES/HYDRAULIC/MECHANICAL/DISC BRAKE CALIPER - REMOVAL)
(4) Remove rear brake rotor. (Refer to 5 - BRAKES/HYDRAULIC/MECHANICAL/ROTOR - REMOVAL)
(5) Remove the dust cap from the rear hub and bearing.
(6) Remove the rear hub and bearing assembly retaining nut and washer.
(7) Remove the rear hub and bearing assembly from the rear spindle.
(8) Remove the rear brake shoe assembly hold-down clip (Fig. 152).
(9) Turn the brake shoe adjuster wheel until the adjuster is at shortest length.
(10) Remove the adjuster assembly from the parking brake shoe assemblies (Fig. 153).
(11) Remove the lower shoe-to-shoe spring (Fig. 154).
(12) Pull the rear brake shoe away from anchor. Remove the rear brake shoe and upper return spring (Fig. 155).
(13) Remove the front brake shoe hold-down clip (Fig. 156). Remove the front brake shoe assembly.

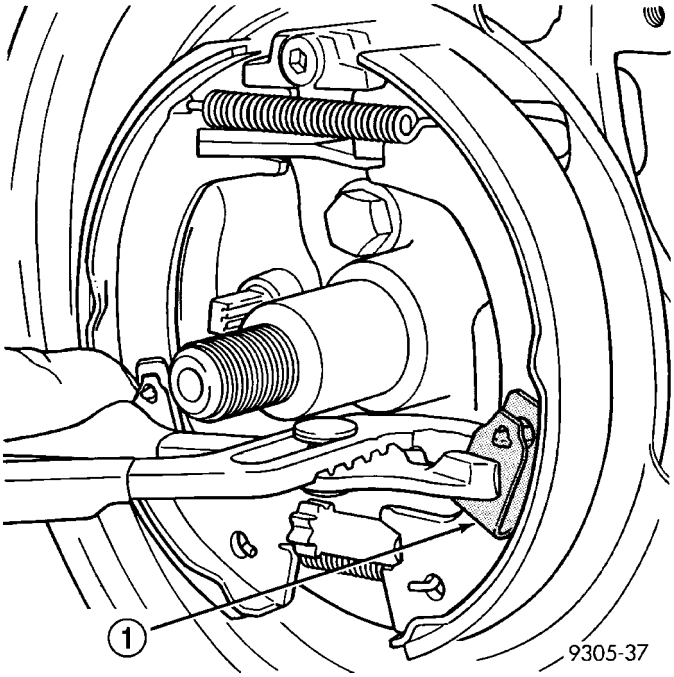

Fig. 152 Rear Brake Shoe Hold-Down Clip

1 - HOLD DOWN CLIP

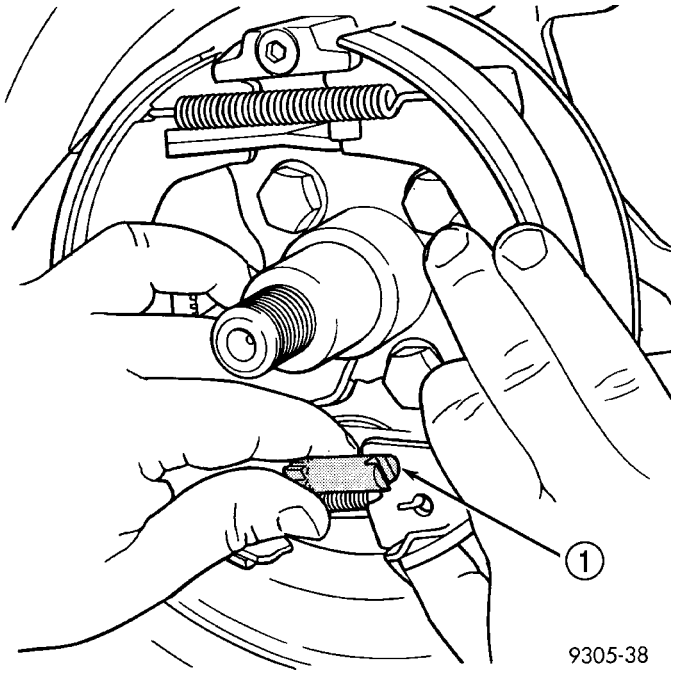

Fig. 153 Parking Brake Shoe Adjuster Assembly

1 - ADJUSTER

INSTALLATION

NOTE: Perform Step 1 through Step 12 on each side of the vehicle to complete shoe set installation, then proceed to Step 13.

(1) Install the front brake shoe and secure it in place with a hold-down clip (Fig. 156).
(2) Install the rear brake shoe and the upper shoe return spring (Fig. 155). Pull the rear brake shoe over the anchor block until it is properly located on the adapter.
(3) Install the lower shoe-to-shoe return spring (Fig. 154).
(4) Install the brake shoe adjuster assembly with the star wheel towards the rear (Fig. 153).

SHOES - PARKING BRAKE (Continued)

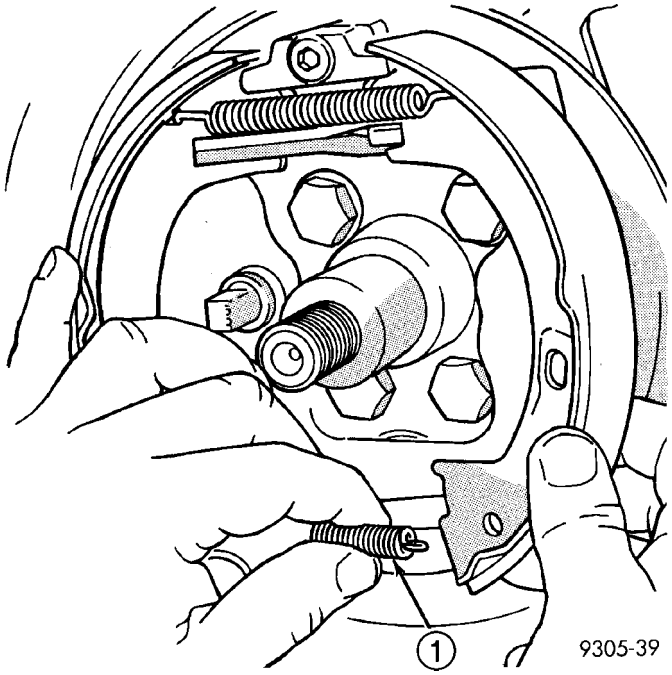

Fig. 154 Brake Shoe Lower Return Spring

1 - LOWER SPRING

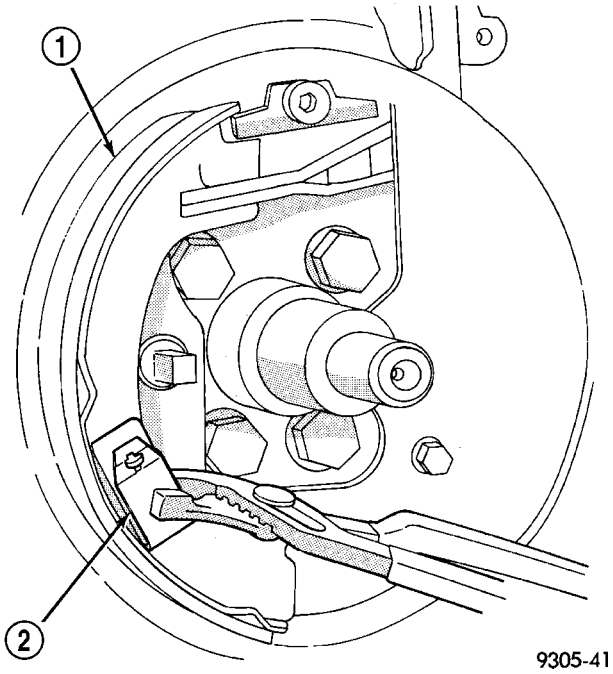

Fig. 156 Front Hold Down Clip And Brake Shoe

2 - HOLD DOWN CLIP

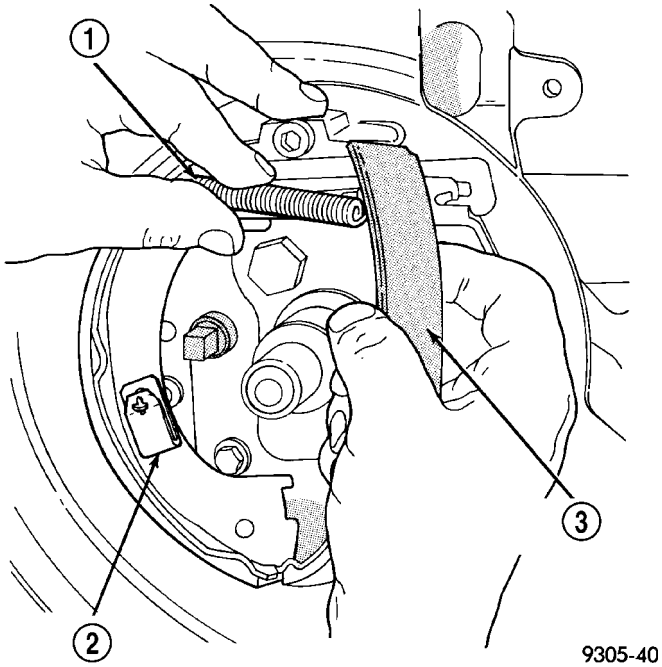

Fig. 155 Brake Shoe and Upper Spring

1 - UPPER SPRING
2 - HOLD DOWN CLIP
3 - REAR PARKING BRAKE SHOE

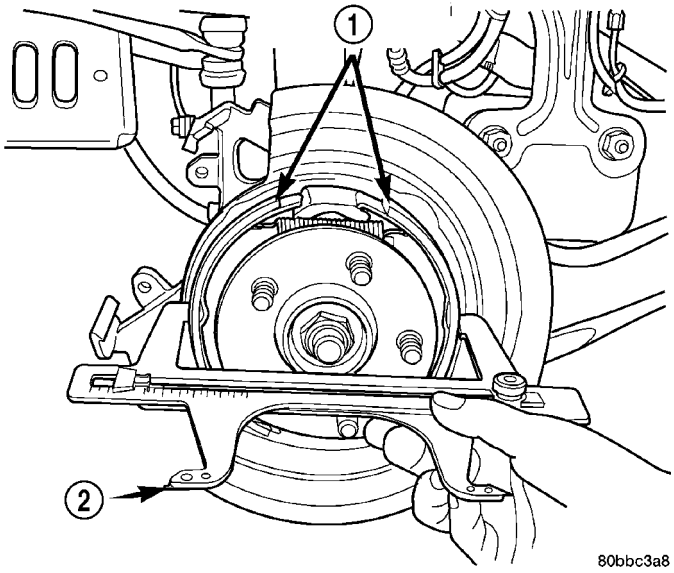

Fig. 157 Measuring Brake Shoes

1 - REAR PARKING BRAKE SHOES
2 - BRAKE SHOE GAUGE

(5) Install the rear brake shoe hold down clip (Fig. 152).

(6) Adjust the parking brake shoes to a diameter of 171 mm (6.75 inch) (Fig. 157).

(7) Install the rear hub and bearing assembly on spindle.

(8) Install a new hub and bearing assembly retaining nut. Tighten the retaining nut to a torque of 217 N·m (160 ft. lbs.).

(9) Install the hub and bearing dust cap.

SHOES - PARKING BRAKE (Continued)

(10) Install the rear brake rotor. (Refer to 5 - BRAKES/HYDRAULIC/MECHANICAL/ROTOR - INSTALLATION)

(11) Install rear disc brake caliper. (Refer to 5 - BRAKES/HYDRAULIC/MECHANICAL/DISC BRAKE CALIPER - INSTALLATION)

(12) Install the tire and wheel assembly. Tighten the wheel mounting nuts to a torque of 135 N·m (100 ft. lbs.).

(13) Adjust the parking brake shoes as necessary. (Refer to 5 - BRAKES/PARKING BRAKE/SHOES - ADJUSTMENTS)

(14) Lower the vehicle.

ADJUSTMENTS

ADJUSTMENT

NOTE: The parking brake shoes used in the drum-in-hat park brake system do not automatically adjust to compensate for brake shoe lining wear. Therefore, it is necessary to manually adjust the parking brake shoes.

NOTE: Before proceeding, (Refer to 5 - BRAKES - WARNING) (Refer to 5 - BRAKES - CAUTION).

(1) Verify the parking brake lever is in the released position.

(2) Raise the vehicle. (Refer to LUBRICATION & MAINTENANCE/HOISTING - STANDARD PROCEDURE)

(3) Remove the rubber plug from the adjusting hole in the disc brake caliper adapter.

(4) Adjust the parking brakes. Use the first bullet point for the adjustment of the left side parking brake shoes. Use the second bullet point for the adjustment of the right side parking brake shoes.

- Insert a medium size screwdriver through adjustment hole in the left backing plate. Position the screwdriver against the star wheel on the parking brake shoe adjuster. Using the screwdriver, rotate the star wheel downward until a slight drag is noticed when turning the rear tire and wheel assembly. Then, using the screwdriver, slowly rotate the star wheel upward, backing off the adjuster, just enough to allow the rear tire and wheel assembly to rotate without the parking brake shoes dragging. Do not back off the adjuster star wheel more than two clicks past the point of no drag. The parking brake shoe-to-drum clearance is now properly set.
- Insert a medium size screwdriver through adjustment hole in the right backing plate. Position the screwdriver against the star wheel on the parking brake shoe adjuster. Using the screwdriver, rotate the star wheel upward until a slight drag is noticed when turning the rear tire and wheel assembly. Then, using the screwdriver, slowly rotate the star wheel downward, backing off the adjuster, just enough to allow the rear tire and wheel assembly to rotate without the parking brake shoes dragging. Do not back off the adjuster star wheel more that two clicks past the point of no drag. The parking brake shoe-to-drum clearance is now properly set.

(5) Install the rubber plug in the adjusting holes of the disc brake caliper adapter.

(6) Lower the vehicle until the rear tires are just clearing the floor.

(7) Reach inside the vehicle and fully apply and release the park brakes two times after adjusting the parking brake shoes.

(8) With the parking brake lever in the fully applied position, attempt to hand rotate each rear tire and wheel assembly to ensure that the parking brake shoes are working.

(9) With the parking brake lever in the released position, hand rotate each rear tire and wheel assembly to ensure that the parking brake shoes are not dragging.

BRAKES - ABS

DESCRIPTION

DESCRIPTION - ANTILOCK BRAKE SYSTEM - MK20E

The Antilock Brake System (ABS) prevents wheel lockup under braking conditions on virtually any type of road surface. Antilock braking is desirable because a vehicle that is stopped without locking the wheels retains directional stability and some steering capability. This allows the driver to retain greater control of the vehicle during braking.

Early production vehicles feature an antilock brake system designated Mark 20e (MK20e). This system is available with or without traction control.

The traction control system reduces wheel slip and maintains traction at driving speeds below 64 km/h (40 mph) when road conditions call for traction assistance. For more information on traction control, (Refer to 5 - BRAKES - ABS - DESCRIPTION).

All vehicles equipped with ABS use electronic variable brake proportioning (EVBP) to balance front-to-rear braking when the brakes are applied in the partial braking range. For more information on electronic brake distribution, (Refer to 5 - BRAKES - ABS - DESCRIPTION).

BRAKES - ABS (Continued)

This system shares most base brake hardware used on vehicles without ABS. Included in the ABS system is an integrated control unit (ICU) and four wheel speed sensors. Although similar to vehicles without ABS, a different master cylinder and brake tubes are used.

The MK20e ICU is made up of the Hydraulic Control Unit (HCU) and the Controller Antilock Brake (CAB). For additional information on these components, (Refer to 5 - BRAKES/HYDRAULIC/MECHANICAL/HCU (HYDRAULIC CONTROL UNIT) - DESCRIPTION) (Refer to 8 - ELECTRICAL/ELECTRONIC CONTROL MODULES/CONTROLLER ANTILOCK BRAKE - DESCRIPTION).

DESCRIPTION - ANTILOCK BRAKE SYSTEM - MK25E

The Antilock Brake System (ABS) prevents wheel lockup under braking conditions on virtually any type of road surface. Antilock braking is desirable because a vehicle that is stopped without locking the wheels retains directional stability and some steering capability. This allows the driver to retain greater control of the vehicle during braking.

Normal Launch production vehicles are equipped with an antilock brake system designated MK25e. This system is available with or without traction control.

The traction control system reduces wheel slip and maintains traction at driving speeds below 64 km/h (40 mph) when road conditions call for traction assistance. For more information on traction control, (Refer to 5 - BRAKES - ABS - DESCRIPTION).

All vehicles equipped with ABS use electronic variable brake proportioning (EVBP) to balance front-to-rear braking when the brakes are applied in the partial braking range. For more information on electronic brake distribution, (Refer to 5 - BRAKES - ABS - DESCRIPTION).

This system shares most base brake hardware used on vehicles without ABS. Included in the ABS system is an integrated control unit (ICU) and four wheel speed sensors. Although similar to vehicles without ABS, a different master cylinder and brake tubes are used.

The MK25e ICU is made up of the Hydraulic Control Unit (HCU) and the Antilock Brake Module (ABM). For additional information on these components, (Refer to 5 - BRAKES/HYDRAULIC/MECHANICAL/HCU (HYDRAULIC CONTROL UNIT) - DESCRIPTION) (Refer to 8 - ELECTRICAL/ELECTRONIC CONTROL MODULES/ANTILOCK BRAKE MODULE - DESCRIPTION).

DESCRIPTION - ELECTRONIC VARIABLE BRAKE PROPORTIONING

Vehicles equipped with ABS use electronic variable brake proportioning (EVBP) to balance front-to-rear braking. The EVBP is used in place of a rear proportioning valve. The EVBP system uses the ABS system to control the slip of the rear wheels in partial braking range. The braking force of the rear wheels is controlled electronically by using the inlet and outlet valves located in the integrated control unit (ICU).

EVBP activation is invisible to the customer since there is no pump motor noise or brake pedal feedback.

DESCRIPTION - TRACTION CONTROL SYSTEM

Traction control reduces wheel slip and maintains traction at the driving wheels at speeds below 64 km/h (40 mph) when road surfaces are slippery. The traction control system reduces wheel slip by braking the wheel that is losing traction.

The traction control system may be turned off or on by depressing the traction control switch button located on the instrument panel (Fig. 1).

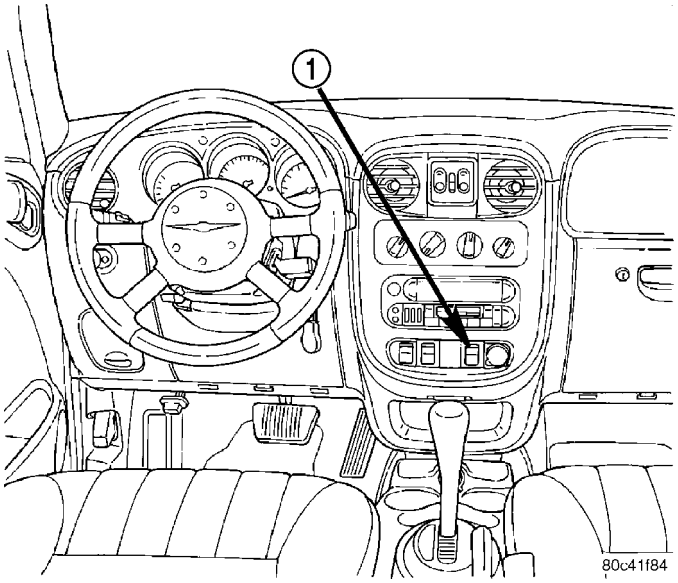

Fig. 1 Traction Control Switch Location

1 - TRACTION CONTROL SWITCH

BRAKES - ABS (Continued)

OPERATION

OPERATION - ANTILOCK BRAKE SYSTEM

There are a few performance characteristics of the MK20e and MK25e Antilock Brake Systems that may at first seem abnormal, but in fact are normal. These characteristics are described below.

NORMAL BRAKING

Under normal braking conditions, the ABS functions the same as a standard base brake system with a diagonally split master cylinder and conventional vacuum assist.

ABS BRAKING

ABS operation is available at all vehicle speeds above 5–8 km/h (3–5 mph). If a wheel locking tendency is detected during a brake application, the brake system enters the ABS mode. During ABS braking, hydraulic pressure in the four wheel circuits is modulated to prevent any wheel from locking. Each wheel circuit is designed with a set of electric solenoids to allow modulation, although for vehicle stability, both rear wheel solenoids receive the same electrical signal. Wheel lockup may be perceived at the very end of an ABS stop and is considered normal.

During an ABS stop, the brakes hydraulic system is still diagonally split. However, the brake system pressure is further split into four control channels. During antilock operation of the vehicle's brake system, the wheels are controlled independently and are on separate control channels.

The system can build, hold and release pressure at each wheel, depending on signals generated by the wheel speed sensors (WSS) at each wheel and received at the Controller Antilock Brake (MK20e) or Antilock Brake Module (MK25e).

NOISE AND BRAKE PEDAL FEEL

During ABS braking, some brake pedal movement may be felt. In addition, ABS braking will create ticking, popping, or groaning noises heard by the driver. This is normal and is due to pressurized fluid being transferred between the master cylinder and the brakes. If ABS operation occurs during hard braking, some pulsation may be felt in the vehicle body due to fore-and-aft movement of the suspension as brake pressures are modulated.

At the end of an ABS stop, ABS is turned off when the vehicle is slowed to a speed of 5–6 km/h (3–4 mph). There may be a slight brake pedal drop anytime that the ABS is deactivated, such as at the end of the stop when the vehicle speed is less than 5 km/h (3 mph) or during an ABS stop where ABS is no longer required. These conditions exist when a vehicle is being stopped on a road surface with patches of ice, loose gravel, or sand on it. Also, stopping a vehicle on a bumpy road surface activates ABS because of the wheel hop caused by the bumps.

TIRE NOISE AND MARKS

Although the ABS system prevents complete wheel lockup, some wheel slip is desired in order to achieve optimum braking performance. Wheel slip is defined as follows: 0 percent slip means the wheel is rolling freely and 100 percent slip means the wheel is fully locked. During brake pressure modulation, wheel slip is allowed to reach up to 25–30 percent. This means that the wheel rolling velocity is 25–30 percent less than that of a free rolling wheel at a given vehicle speed. This slip may result in some tire chirping, depending on the road surface. This sound should not be interpreted as total wheel lockup.

Complete wheel lockup normally leaves black tire marks on dry pavement. The ABS will not leave dark black tire marks since the wheel never reaches a fully locked condition. However, tire marks may be noticeable as light patched marks.

START-UP CYCLE

When the ignition is turned on, a popping sound and a slight brake pedal movement may be noticed. The ABS warning indicator lamp will also be on for up to 5 seconds after the ignition is turned on. These conditions occur as part of an ABS self-diagnosis test performed by the antilock brake system. The popping noise is the result of brief activation of the solenoids inside the integrated control unit (ICU).

DRIVE-OFF CYCLE

When the vehicle is first driven off, a humming may be heard or felt by the driver at approximately 25–40 km/h (15–25 mph). This is caused by brief activation of the ABS pump motor on the ICU and is a normal function of ABS as the system is performing a diagnosis check.

PREMATURE ABS CYCLING

Symptoms of premature ABS cycling include: clicking sounds from the solenoid valves; pump/motor running; and pulsations in the brake pedal. Premature ABS cycling can occur at any braking rate of the vehicle and on any type of road surface.

Premature ABS cycling is a condition that needs to be correctly assessed when diagnosing problems with the antilock brake system. It may be necessary to use a scan tool to detect and verify premature ABS cycling.

Check the following common causes when diagnosing premature ABS cycling: damaged tone wheels; incorrect tone wheels; damaged steering knuckle

wheel speed sensor mounting bosses; loose wheel speed sensor mounting bolts; excessive tone wheel runout; excessively large tone wheel-to-wheel speed sensor air gap, or a damaged speed sensor head face. Give special attention to these components when diagnosing a vehicle exhibiting premature ABS cycling.

After diagnosing the defective component, repair or replace it as required. When the component repair or replacement is completed, test drive the vehicle to verify that premature ABS cycling has been corrected.

OPERATION - ELECTRONIC VARIABLE BRAKE PROPORTIONING

Upon entry into EVBP the inlet valve for the rear brake circuit is switched on so that the fluid supply from the master cylinder is shut off. In order to decrease the rear brake pressure, the outlet valve for the rear brake circuit is pulsed. This allows fluid to enter the low pressure accumulator (LPA) in the hydraulic control unit (HCU) resulting in a drop in fluid pressure to the rear brakes. In order to increase the rear brake pressure, the outlet valve is switched off and the inlet valve is pulsed. This increases the pressure to the rear brakes. This back-and-forth process will continue until the required slip difference is obtained. At the end of EVBP braking (brakes released) the fluid in the LPA drains back to the master cylinder by switching on the outlet valve and draining through the inlet valve check valve. At the same time the inlet valve is switched on in case of another brake application.

The EVBP will remain functional during many ABS fault modes. If both the red BRAKE and amber ABS warning indicators are illuminated, the EVBP may not be functioning.

OPERATION - TRACTION CONTROL SYSTEM - MK20E

The CAB monitors wheel speed. During acceleration, if the CAB detects front (drive) wheel slip and the brakes are not applied, the CAB enters traction control mode. Traction control operation proceeds in the following order:

(1) Close the normally open traction control (TC) valves.

(2) Start the pump/motor and supply volume and pressure to the front (drive) hydraulic circuit. (The pump/motor runs continuously during traction control operation.)

(3) Open and close the build and decay solenoid valves to maintain minimum wheel slip and maximum traction.

The cycling of the build and decay valves during traction control is similar to that during antilock braking, except the valves work to control wheel spin by applying the brakes, whereas the ABS function is to control wheel skid by releasing the brakes.

Two pressure relief shuttle valves allow pressure and volume to return to the master cylinder reservoir when not consumed by the build and decay valves. These valves are necessary because the pump/motor supplies more volume than the system requires.

If the brakes are applied at anytime during a traction control cycle, the brake lamp switch triggers the control module to switch off traction control.

The traction control function indicator illuminates during a traction control cycle, displaying TRAC on the instrument panel.

The traction control system is enabled at each ignition cycle. It may be turned off by depressing the traction control switch button. The traction control function indicator (TRAC OFF) illuminates immediately upon depressing the button. Pressing this button again or turning off and restarting the vehicle will enable the traction control system.

If the CAB calculates that the brake temperatures are high, the traction control system becomes inoperative until a time-out period has elapsed. During this “thermo-protection mode,” the traction control function indicator illuminates TRAC OFF; note that no trouble code is registered.

OPERATION - TRACTION CONTROL SYSTEM - MK25E

The ABM monitors wheel speed. During acceleration, if the ABM detects front (drive) wheel slip and the brakes are not applied, the ABM enters traction control mode. Traction control operation proceeds in the following order:

(1) Close the normally open traction control (TC) valves.

(2) Start the pump/motor and supply volume and pressure to the front (drive) hydraulic circuit. (The pump/motor runs continuously during traction control operation.)

(3) Open and close the build and decay solenoid valves to maintain minimum wheel slip and maximum traction.

The cycling of the build and decay valves during traction control is similar to that during antilock braking, except the valves work to control wheel spin by applying the brakes, whereas the ABS function is to control wheel skid by releasing the brakes.

Two pressure relief shuttle valves allow pressure and volume to return to the master cylinder reservoir when not consumed by the build and decay valves. These valves are necessary because the pump/motor supplies more volume than the system requires.

BRAKES - ABS (Continued)

If the brakes are applied at anytime during a traction control cycle, the brake lamp switch triggers the control module to switch off traction control.

The traction control function indicator illuminates during a traction control cycle, displaying TRAC on the instrument panel.

The traction control system is enabled at each ignition cycle. It may be turned off by depressing the traction control switch button. The traction control function indicator (TRAC OFF) illuminates immediately upon depressing the button. Pressing this button again or turning off and restarting the vehicle will enable the traction control system.

If the ABM calculates that the brake temperatures are high, the traction control system becomes inoperative until a time-out period has elapsed. During this "thermo-protection mode," the traction control function indicator illuminates TRAC OFF; note that no trouble code is registered.

CAUTION

The ABS uses an electronic control module. This module is designed to withstand normal current draws associated with vehicle operation. Care must be taken to avoid overloading the circuits.

CAUTION: In testing for open or short circuits, do not ground or apply voltage to any of the circuits unless instructed to do so for a diagnostic procedure.

CAUTION: These circuits should only be tested using a high impedance multi-meter or the designated scan tool as described in this section. Power should never be removed or applied to any control module with the ignition in the ON position. Before removing or connecting battery cables, fuses, or connectors, always turn the ignition to the OFF position.

CAUTION: The CAB (MK20e) 25-way connector should never be connected or disconnected with the ignition switch in the ON position.

CAUTION: The ABM (MK25e) 47-way connector should never be connected or disconnected with the ignition switch in the ON position.

CAUTION: This vehicle utilizes active wheel speed sensors. Do not apply voltage to wheel speed sensors at any time.

CAUTION: Use only factory wiring harnesses. Do not cut or splice wiring to the brake circuits. The addition of aftermarket electrical equipment (car phone, radar detector, citizen band radio, trailer lighting, trailer brakes, etc.) on a vehicle equipped with antilock brakes may affect the function of the antilock brake system.

CAUTION: When performing any service procedure on a vehicle equipped with ABS, do not apply a 12-volt power source to the ground circuit of the pump motor in the HCU. Doing this will damage the pump motor and will require replacement of the entire HCU.

CAUTION: An attempt to remove or disconnect certain system components may result in improper system operation. Only those components with approved removal and installation procedures in this manual should be serviced.

CAUTION: If welding work is to be performed on the vehicle using an electric arc welder, the CAB (MK20e) or ABM (MK25e) connector should be disconnected during the welding operation.

CAUTION: Many components of the ABS System are not serviceable and must be replaced as an assembly. Do not disassemble any component which is not designed to be serviced.

CAUTION: Only the recommended jacking or hoisting positions for this vehicle are to be used whenever it is necessary to lift a vehicle. Failure to raise a vehicle from the recommended locations could result in lifting a vehicle by the hydraulic control unit mounting bracket. Lifting a vehicle by the hydraulic control unit mounting bracket will result in damage to the mounting bracket and the hydraulic control unit.

CAUTION: Brake fluid will damage painted surfaces. If brake fluid is spilled on any painted surface, wash off with water immediately.

DIAGNOSIS AND TESTING - INSPECTION AND ROAD TEST

(1) Visually inspect the ABS for damaged or disconnected components and connectors.

(2) Verify the brake lamps are operational. If they are not, repair them prior to continuing.

BRAKES - ABS (Continued)

(3) Connect a scan tool to the Data Link Connector located under the instrument panel to the left of the steering column (Fig. 2). If the scan tool does not power-up, check the power and ground supplies to the connector.

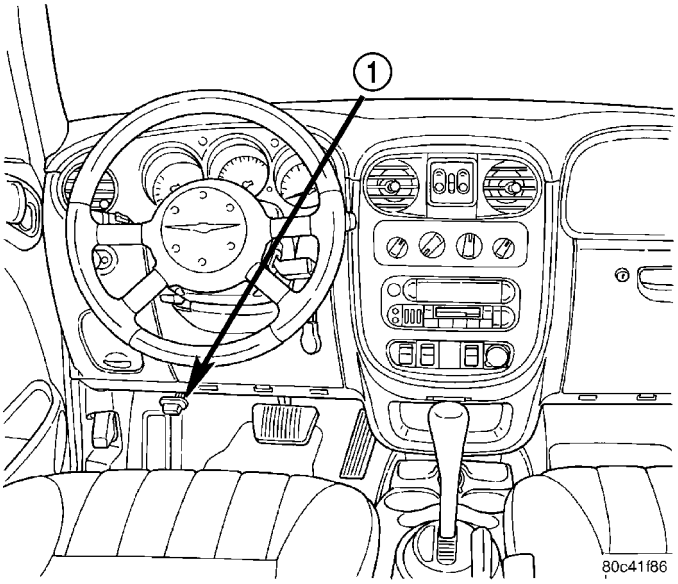

Fig. 2 Data Link Connector Location

1 - DATA LINK CONNECTOR (DLC)

(4) Turn the ignition key to the ON position. Using the scan tool, select ANTILOCK BRAKES.

(5) Read and record any Diagnostic Trouble Codes (DTCs). If any DTCs are present, refer to the appropriate chassis diagnostic information.

NOTE: Diagnostic trouble codes (DTCs) are kept in the controller's memory until either erased by the technician using the scan tool, or erased automatically after 3500 miles or 255 ignition key cycles, whichever occurs first. DTCs are retained by the controller even if the ignition is turned off or the battery is disconnected. More than one DTC can be stored at a time. When accessed, the number of occurrences and the DTC that is stored are displayed.

If no problems are observed, it will be necessary to road test the vehicle.

Many ABS conditions judged to be a problem by the driver may be normal operating conditions. To become familiarized with the normal operating characteristics of this antilock brake system, (Refer to 5 - BRAKES - ABS OPERATION).

WARNING: CONDITIONS THAT RESULT IN TURNING ON THE RED BRAKE WARNING INDICATOR LAMP MAY INDICATE REDUCED BRAKING ABILITY.

Before road testing a brake complaint vehicle, note whether the red BRAKE warning indicator lamp, amber ABS warning indicator lamp, or both are turned on. If it is the red BRAKE warning indicator, there is a brake hydraulic problem that must be corrected before driving the vehicle (Refer to 5 - BRAKES - BASE - DIAGNOSIS AND TESTING). If the red BRAKE warning indicator is illuminated, there is also a possibility that there is an ABS problem and the amber ABS warning indicator is not able to illuminate, so the MIC turns on the red BRAKE warning indicator by default.

If the amber ABS warning indicator is on, road test the vehicle as described below. While only the amber ABS warning indicator is on, the ABS is not functional. The ability to stop the car using the base brake system should not be affected.

(6) Turn the key to the OFF position and then back to the ON position. Note whether the amber ABS warning indicator lamp continues to stay on.

(7) If the amber ABS warning indicator lamp stays on, shift into gear and drive the car to a speed of approximately 25 km/h (15 mph) to complete the ABS Start-Up and Drive-Off Cycles (Refer to 5 - BRAKES - ABS - OPERATION). If at this time the amber ABS warning indicator lamp stays on, refer to the Appropriate Diagnostic Information.

(8) If the amber ABS warning indicator lamp goes out at any time, drive the vehicle a short distance. Accelerate the vehicle to a speed of at least 64 km/h (40 mph). Bring the vehicle to a complete stop, braking hard enough to cause the ABS to cycle. Repeat this action several times. Using the scan tool, read and record any Diagnostic Trouble Codes (DTCs). If any DTCs are present, refer to the Appropriate Diagnostic Information.

STANDARD PROCEDURE - ANTILOCK BRAKE SYSTEM BLEEDING

The base brake's hydraulic system must be bled anytime air enters the hydraulic system. The ABS though, particularly the ICU (HCU), should only need to be bled when the HCU is replaced or removed from the vehicle. The ABS must always be bled anytime it is suspected that the HCU has ingested air. Under most circumstances that require the bleeding of the brakes hydraulic system, only the base brake hydraulic system needs to be bled.

When bleeding the ABS system, the following bleeding sequence must be followed to insure complete and adequate bleeding.

(1) Make sure all hydraulic fluid lines are installed and properly torqued.

(2) Connect the scan tool to the Data Link Connector. The connector is located under the lower steering column cover to the left of the steering column.

BRAKES - ABS (Continued)

(3) Using the scan tool, check to make sure the CAB (MK20e) or ABM (Mk25e) does not have any fault codes stored. If it does, clear them using the scan tool.

WARNING: WHEN BLEEDING THE BRAKE SYSTEM WEAR SAFETY GLASSES. A CLEAR BLEED TUBE MUST BE ATTACHED TO THE BLEEDER SCREWS AND SUBMERGED IN A CLEAR CONTAINER FILLED PART WAY WITH CLEAN BRAKE FLUID. DIRECT THE FLOW OF BRAKE FLUID AWAY FROM YOURSELF AND THE PAINTED SURFACES OF THE VEHICLE. BRAKE FLUID AT HIGH PRESSURE MAY COME OUT OF THE BLEEDER SCREWS WHEN OPENED.

(4) Bleed the base brake system using the standard pressure or manual bleeding procedure. (Refer to 5 - BRAKES - BASE - STANDARD PROCEDURE)

(5) Using the scan tool, select ANTILOCK BRAKES, followed by MISCELLANEOUS, then BLEED BRAKES. Follow the instructions displayed. When the scan tool displays TEST COMPLETED, disconnect the scan tool and proceed.

(6) Bleed the base brake system a second time. Check brake fluid level in the reservoir periodically to prevent emptying, causing air to enter the hydraulic system.

(7) Fill the master cylinder reservoir to the full level.

(8) Test drive the vehicle to be sure the brakes are operating correctly and that the brake pedal does not feel spongy.

REAR SENSOR	0.50 – 1.25 mm 0.019 – 0.049 in.

FRONT WHEEL SPEED SENSOR

DESCRIPTION

The antilock brake system uses two-wire wheel speed sensors, known as active wheel speed sensors. The sensors use an electronic principle known as magnetoresistive to help increase performance and durability. The sensors convert wheel speed into a small digital signal. A wheel speed sensor is used at each wheel. The gear (tooth) type tone wheel serves as the trigger mechanism for each sensor. At each wheel of the vehicle there is one wheel speed sensor and one tone wheel.

The front wheel speed sensors are attached to bosses in the steering knuckles (Fig. 3) (Fig. 4). There is a heat shield mounted between each sensor and the knuckle. The tone wheel is an integral part of the outboard constant velocity joint located in the front axle shaft.

WSS air gaps are not adjustable. The initial factory WSS air gap specification can be found in SPECIFICATIONS. Each WSS is serviced individually. The tone wheels are serviced as part of the drive shaft.

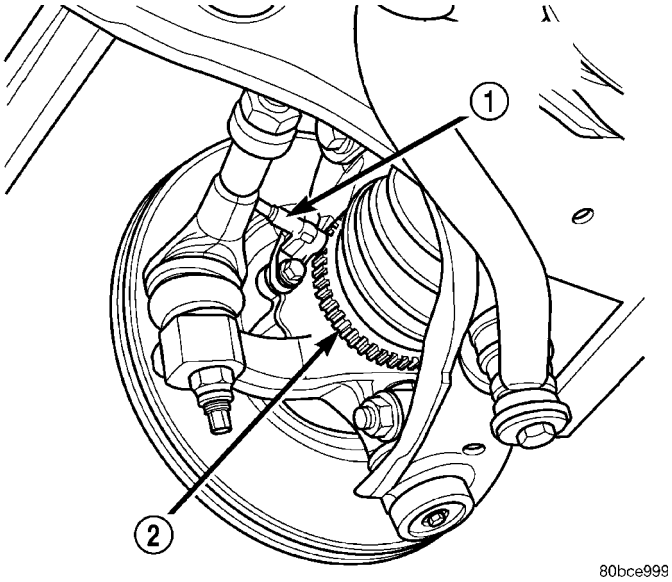

Fig. 3 Left Front Wheel Speed Sensor (Heat Shield Not Shown)

1 - LEFT FRONT WHEEL SPEED SENSOR
2 - TONE WHEEL

OPERATION

The CAB (MK20e) or ABM (MK25e) sends 12 volts to power an Integrated Circuit (IC) in the sensor. The IC supplies a constant 7 mA power supply to the CAB/ABM. The relationship of the tooth on the tone wheel to the permanent magnet in the sensor, signals the IC to enable a second 7 mA power supply. The

3 - ENGINE OIL FILTER

output of the sensor, sent to the CAB, is a DC voltage signal with changing voltage and current levels. The ground for the IC and the current sense circuit is provided by the CAB/ABM.

When a valley of the tone wheel is aligned with the sensor, the voltage signal is approximately 0.8 volts and a constant 7 mA current is sent to the CAB/ABM. As the tone wheel rotates, the tooth shifts the magnetic field and the IC enables a second 7 mA current source. The CAB/ABM senses a voltage signal of approximately 1.6 volts and 14 mA. The CAB/ABM measures the amperage of the digital signal for each wheel. The resulting signal is interpreted by the CAB/ABM as the wheel speed.

REMOVAL

NOTE: Before proceeding, (Refer to 5 - BRAKES - WARNING) (Refer to 5 - BRAKES - CAUTION).

(1) Raise the vehicle. (Refer to LUBRICATION & MAINTENANCE/HOISTING - STANDARD PROCEDURE).

(2) Disconnect the wheel speed sensor cable connector from the wiring harness on the inside of the frame rail above the front suspension crossmember (Fig. 5). The connector has a locking tab which that must be pulled back before the connector release tang can be depressed, releasing the connection.

(3) If the sensor being removed is a left front, unclip the speed sensor cable from the brake tube on the inside of and under the frame rail (Fig. 6).

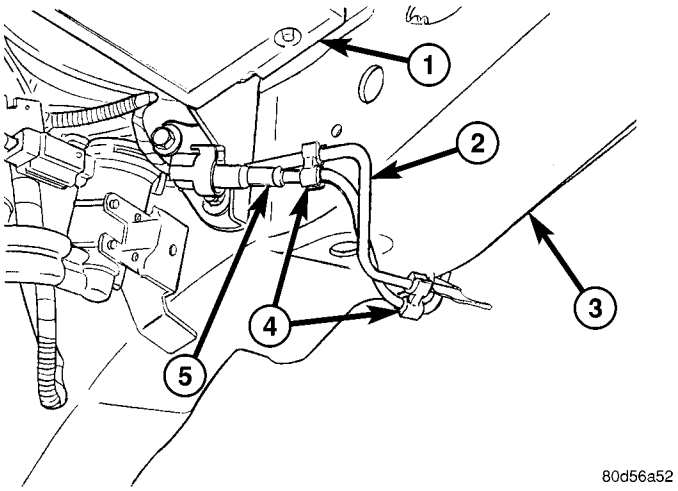

Fig. 6 Left Sensor Routing Along Brake Tube

1 - ABS ICU
2 - BRAKE TUBE
3 - FRAME RAIL
4 - ROUTING CLIPS
5 - WHEEL SPEED SENSOR CABLE

(4) Remove the speed sensor cable grommet from the retaining bracket attached to the brake hose on the outside of the frame rail.

(5) Remove the bolt mounting the wheel speed sensor head to the steering knuckle (Fig. 7).

FRONT WHEEL SPEED SENSOR (Continued)

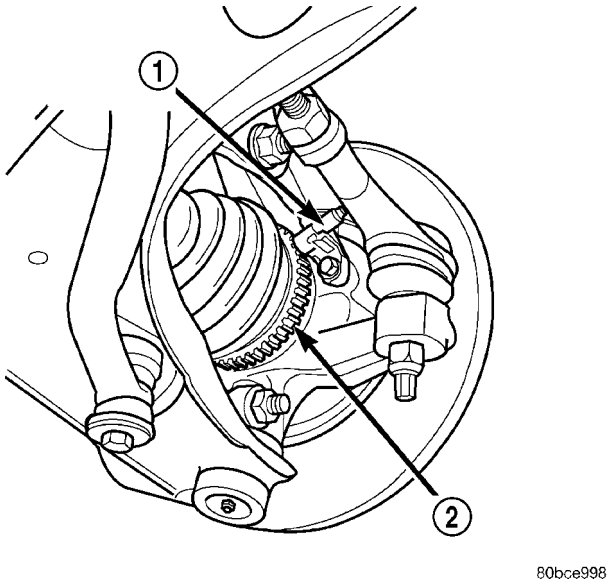

Fig. 7 Wheel Speed Sensor (Heat Shield Not Shown)

1 - RIGHT FRONT WHEEL SPEED SENSOR
2 - TONE WHEEL

CAUTION: When removing a wheel speed sensor from the knuckle, do not use pliers on the sensor head. This may damage the sensor head. If the sensor has seized, use a hammer and a punch to tap the edge of the sensor head ear, rocking the sensor side-to-side until free.

(6) Carefully, remove the sensor head and heat shield from the steering knuckle.

(7) Remove the screw securing the wheel speed sensor to the rear of the strut (Fig. 8). Remove the wheel speed sensor.

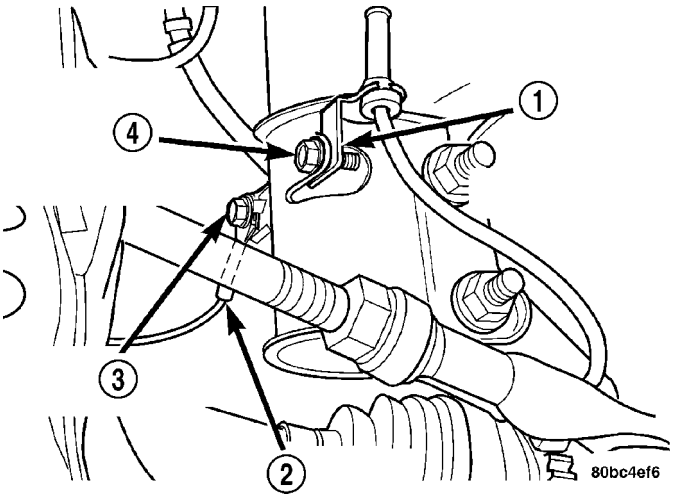

Fig. 8 Wheel Speed Sensor At Strut

1 - ABS WHEEL SPEED SENSOR ROUTING BRACKET (IF EQUIPPED)
2 - GROUND STRAP
3 - GROUND STRAP SCREW
4 - ABS SENSOR BRACKET SCREW (IF EQUIPPED)

INSTALLATION

CAUTION: Failure to install speed sensor cables properly may result in contact with moving parts or an over extension of cables causing an open circuit. Be sure that cables are installed, routed, and clipped properly.

(1) Attach the wheel speed sensor to the strut using the its mounting screw (Fig. 8).

(2) Install the wheel speed sensor head in the steering knuckle (Fig. 7). Install the mounting bolt. Tighten the mounting bolt to a torque of 12 N·m (105 in. lbs.).

(3) From the sensor bracket on the strut, loop the sensor cable upward, then downward at the outside of the frame rail. Install the speed sensor cable grommet onto the retaining bracket attached to the brake hose on the outside of the frame rail.

(4) Loop the wheel speed sensor cable around the bottom of the frame rail and connect it to the wiring harness connector on the inside of the frame rail (Fig. 5). Remember to push in the locking tab on the connector.

(5) If the sensor being installed is the left front, clip the speed sensor cable to the brake tube on the inside of and under the frame rail (Fig. 6).

(6) Install the tire and wheel assembly. Progressively tighten wheel mounting nuts to 135 N·m (100 ft. lbs.).

(7) Lower the vehicle.

(8) Road test vehicle to ensure proper operation of the base brakes and ABS.

REAR WHEEL SPEED SENSOR

DESCRIPTION

The antilock brake system uses two-wire wheel speed sensors, known as active wheel speed sensors. The sensors use an electronic principle known as magnetoresistive to help increase performance and durability. The sensors convert wheel speed into a small digital signal. A wheel speed sensor (WSS) is used at each wheel. The gear (tooth) type tone wheel serves as the trigger mechanism for each sensor. At each wheel of the vehicle there is one wheel speed sensor and one tone wheel.

The rear wheel speed sensors are mounted through the disc brake adapter (Fig. 9) (Fig. 10) or drum brake support plate. The rear tone wheels are mounted to and rotate with the hub and bearing assemblies.

The WSS air gaps are not adjustable. For the WSS air gap specification, (Refer to 5 - BRAKES - ABS - SPECIFICATIONS). Each WSS is serviced individu-

REAR WHEEL SPEED SENSOR (Continued)

ally. The tone wheels are serviced as an assembly with the hub and bearing assemblies.

2 - SHOCK ABSORBER

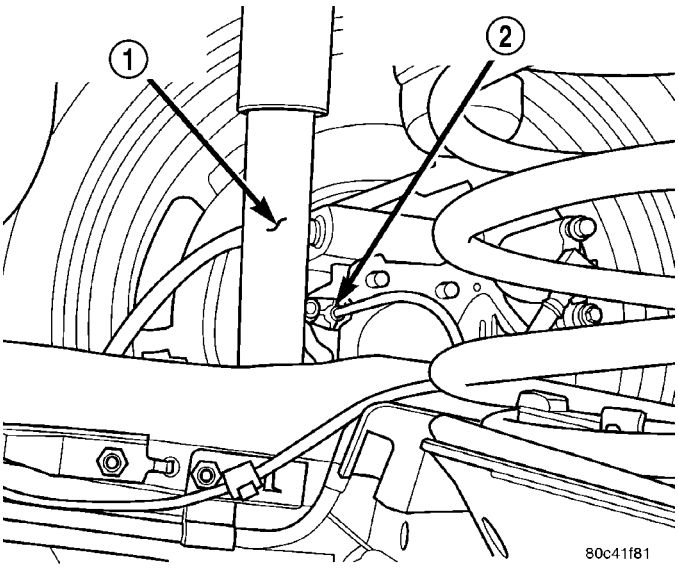

Fig. 10 Right Rear Wheel Speed Sensor

1 - SHOCK ABSORBER
2 - RIGHT REAR WHEEL SPEED SENSOR

OPERATION

The CAB (MK20e) or ABM (MK25e) sends 12 volts to power an Integrated Circuit (IC) in the sensor. The IC supplies a constant 7 mA power supply to the CAB/ABM. The relationship of the tooth on the tone wheel to the permanent magnet in the sensor, signals the IC to enable a second 7 mA power supply. The output of the sensor, sent to the CAB/ABM, is a DC voltage signal with changing voltage and current levels. The ground for the IC and the current sense circuit is provided by the CAB/ABM.

When a valley of the tone wheel is aligned with the sensor, the voltage signal is approximately 0.8 volts and a constant 7 mA current is sent to the CAB/ABM. As the tone wheel rotates, the tooth shifts the magnetic field and the IC enables a second 7 mA current source. The CAB/ABM senses a voltage signal of approximately 1.6 volts and 14 mA. The CAB/ABM measures the amperage of the digital signal for each wheel. The resulting signal is interpreted by the CAB/ABM as the wheel speed.

REMOVAL

NOTE: Before proceeding, (Refer to 5 - BRAKES - WARNING) (Refer to 5 - BRAKES - CAUTION).

(1) Raise the vehicle. (Refer to LUBRICATION & MAINTENANCE/HOISTING - STANDARD PROCEDURE).

(2) Remove the tire and wheel assembly from the vehicle.

(3) Disconnect the wheel speed sensor cable connector from the vehicle wiring harness (Fig. 11). Remove the clip attaching wheel speed sensor cable connector to the vehicle's body.

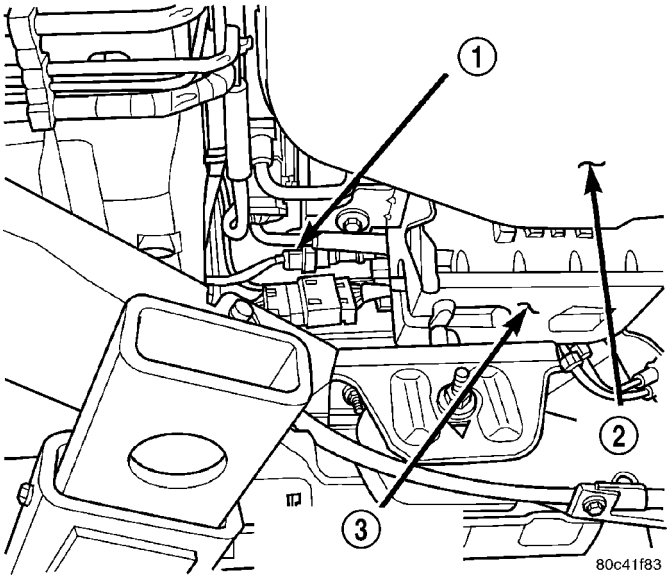

Fig. 11 Wheel Speed Sensor Connector

1 - RIGHT REAR WHEEL SPEED SENSOR CONNECTOR
2 - FUEL TANK
3 - EVAPORATIVE CANISTER

(4) Disconnect the wheel speed sensor cable routing clips running along the brake tube, brake hose and axle trailing arm.

REAR WHEEL SPEED SENSOR (Continued)

CAUTION: When removing a wheel speed sensor from the rear disc brake adapter, do not use pliers on the sensor head. This may damage the sensor head. If the sensor has seized, use a hammer and a punch to tap the edge of the sensor head ear, rocking the sensor side-to-side until free.

(5) Remove the bolt attaching the wheel speed sensor to the rear disc brake adapter or drum brake support plate (Fig. 12), then carefully remove the sensor head from the rear disc brake adapter and vehicle.

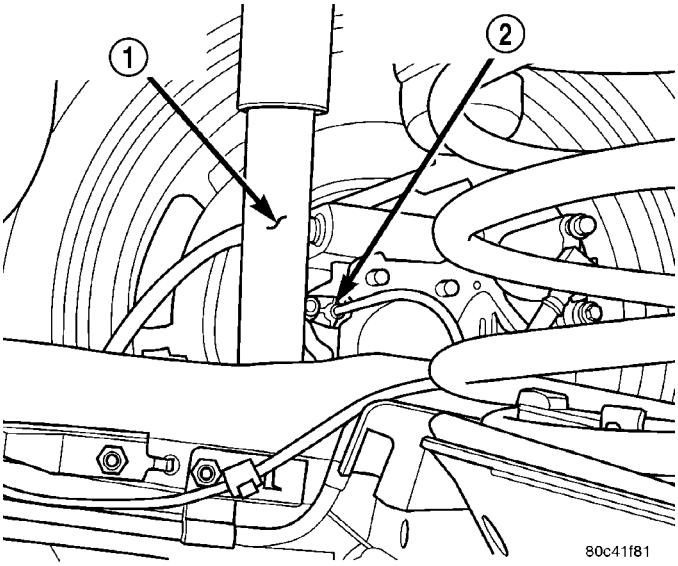

Fig. 12 Wheel Speed Sensor

1 - SHOCK ABSORBER
2 - RIGHT REAR WHEEL SPEED SENSOR

INSTALLATION

CAUTION: Failure to install speed sensor cables properly may result in contact with moving parts or an over extension of cables causing an open circuit. Be sure that cables are installed, routed, and clipped properly.

(1) Install the wheel speed sensor head into the disc brake adapter or drum brake support plate (Fig. 12).

(2) Install the wheel speed sensor mounting bolt. Tighten the mounting bolt to a torque of 12 N·m (105 in. lbs.).

(3) Install wheel speed sensor cable into the routing clips on the brake tube, brake hose and axle trailing arm.

(4) Connect the wheel speed sensor cable connector into vehicle wiring harness (Fig. 11). Install the clip attaching the wheel speed sensor cable connector to vehicle's body.

(5) Install the tire and wheel assembly on vehicle. Progressively tighten wheel mounting nuts to 135 N·m (100 ft. lbs.).

(6) Lower the vehicle.

(7) Road test the vehicle to ensure proper operation of the base brakes and ABS.

TONE WHEEL

DESCRIPTION

The tone wheel is used in conjunction with the wheel speed sensors. (Refer to 5 - BRAKES - ABS/ELECTRICAL/FRONT WHEEL SPEED SENSOR - DESCRIPTION) or (Refer to 5 - BRAKES - ABS/ELECTRICAL/REAR WHEEL SPEED SENSOR - DESCRIPTION)

OPERATION

The tone wheel is used in conjunction with the wheel speed sensors. (Refer to 5 - BRAKES - ABS/ELECTRICAL/FRONT WHEEL SPEED SENSOR - OPERATION) or (Refer to 5 - BRAKES - ABS/ELECTRICAL/REAR WHEEL SPEED SENSOR - OPERATION)

INSPECTION

Tone wheels can cause erratic wheel speed sensor signals. Inspect tone wheels for the following possible causes:

- missing, chipped, or broken teeth
- contact with the wheel speed sensor
- wheel speed sensor to tone wheel alignment
- wheel speed sensor to tone wheel clearance
- excessive tone wheel runout
- tone wheel loose on its mounting surface

If a front tone wheel is found to need replacement, the drive shaft must be replaced. No attempt should be made to replace just the tone wheel. (Refer to 3 - DIFFERENTIAL & DRIVELINE/HALF SHAFT - REMOVAL).

If a rear tone wheel is found to need replacement, the rear hub and bearing must be replaced. No attempt should be made to replace just the tone wheel. (Refer to 2 - SUSPENSION/REAR/HUB / BEARING - REMOVAL).

If wheel speed sensor to tone wheel contact is evident, determine the cause and correct it before replacing the wheel speed sensor or tone wheel.

Check the gap between the speed sensor head and the tone wheel to ensure it is within specifications. For wheel speed sensor air gap specifications, (Refer to 5 - BRAKES - ABS - SPECIFICATIONS).

TONE WHEEL (Continued)

Excessive tone wheel runout can cause erratic wheel speed sensor signals. For tone wheel runout specifications, (Refer to 5 - BRAKES - ABS - SPECIFICATIONS). If tone wheel runout is excessive, determine if it is caused by a defect in the driveshaft assembly or hub and bearing. Replace as necessary.

Tone wheels are pressed onto their mounting surfaces and should not rotate independently from the mounting surface. Replace the front driveshaft or rear hub and bearing as necessary.

TRACTION CONTROL SWITCH

REMOVAL

NOTE: The Traction Control Switch (Fig. 13) is located within the accessory switch bezel on the instrument panel.

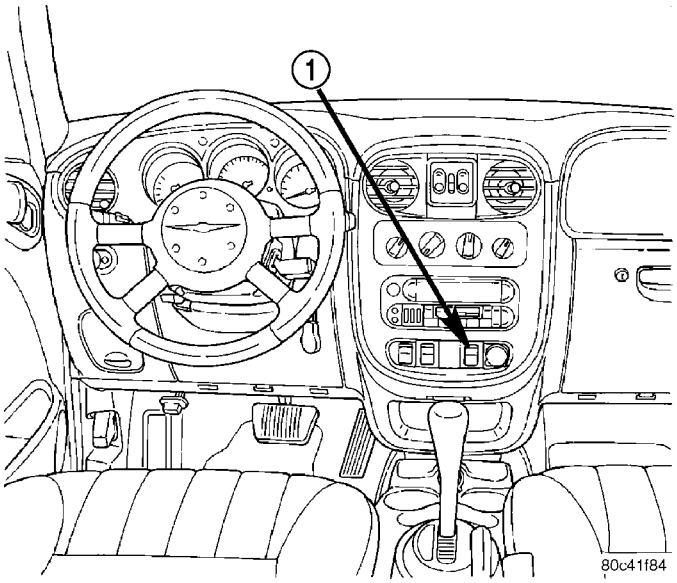

Fig. 13 Traction Control Switch Location

1 - TRACTION CONTROL SWITCH

(1) Remove the accessory switch bezel and then remove the traction control switch from it. (Refer to 23 - BODY/INSTRUMENT PANEL/ACCESSORY SWITCH BEZEL - REMOVAL)

INSTALLATION

(1) Install the traction control switch in the accessory switch bezel, then install the bezel on the instrument panel. (Refer to 23 - BODY/INSTRUMENT PANEL/ACCESSORY SWITCH BEZEL - INSTALLATION)

(2) Road test the vehicle to ensure proper operation of the switch and ABS.

HYDRAULIC CONTROL UNIT (HCU)

DESCRIPTION

DESCRIPTION - MK20E

On early production vehicles equipped with the MK20e ABS, the hydraulic control unit (HCU) is mounted to the CAB as part of the ICU. The HCU controls the flow of brake fluid to the brakes using a series of valves and accumulators. A pump/motor is mounted on the HCU to supply build pressure to the brakes during an ABS stop.

VALVES AND SOLENOIDS

The valve block contains four inlet valves and four outlet solenoid valves. The inlet valves are spring-loaded in the open position and the outlet valves are spring-loaded in the closed position during normal braking. The fluid is allowed to flow from the master cylinder to the wheel brakes.

During an ABS stop, these valves cycle to maintain the proper slip ratio for each wheel. The inlet valve closes preventing further pressure increase and the outlet valve opens to provide a path from the wheel brake to the HCU accumulators and pump/motor. This releases (decays) pressure from the wheel brake, thus releasing the wheel from excessive slippage. Once the wheel is no longer slipping, the outlet valve is closed and the inlet valve is opened to reapply (build) pressure.

If the ABS includes the traction control feature, there are four other valves in the HCU. Two traction control (TC) valves, mounted in the HCU valve block, are normally in the open position and close only when the traction control is applied. There are also two shuttle valves which control pressure return to the master cylinder under ABS and traction control conditions.

These TC valves are used to isolate the rear (non-driving) wheels of the vehicle from the hydraulic pressure that the HCU pump/motor is sending to the front (driving) wheels when traction control is being applied. The rear brakes need to be isolated from the master cylinder when traction control is being applied so the rear wheels do not drag.

HYDRAULIC CONTROL UNIT (HCU) (Continued)

BRAKE FLUID ACCUMULATORS

There are two fluid accumulators in the HCU: one for the primary hydraulic circuit, and one for the secondary hydraulic circuit. Each hydraulic circuit uses a 3 cc accumulator.

The fluid accumulators temporarily store brake fluid that is removed from the wheel brakes during an ABS cycle. This stored fluid is used by the pump/motor to provide build pressure for the brake hydraulic system. When the antilock stop is complete, the accumulators are drained by the pump/motor.

There are two noise dampening chambers in the HCU on this vehicle equipped with traction control.

PUMP/MOTOR

There are two pump assemblies in the HCU: one for the primary hydraulic circuit, and one for the secondary hydraulic circuit. Both pumps are driven by a common electric motor. This DC-type motor is integral to the HCU and is controlled by the CAB.

The pump/motor provides the extra amount of brake fluid needed during antilock braking. Brake fluid is released to the accumulators when the outlet valve is opened during an antilock stop. The pump mechanism consists of two opposing pistons operated by an eccentric camshaft. In operation, these pistons are used to purge fluid from the accumulators back into the master cylinder circuits. When the antilock stop is complete, the pump/motor drains the accumulators.

The pump motor is also used to build pressure when the system goes into traction control mode.

The CAB may turn on the pump/motor when an antilock stop is detected. The pump/motor continues to run during the antilock stop and is turned off after the stop is complete. Under some conditions, the pump/motor runs to drain the accumulators during the next drive-off.

The pump/motor is not a serviceable item; if it requires replacement, the HCU must be replaced.

For more information, (Refer to 5 - BRAKES/HYDRAULIC/MECHANICAL/HCU (HYDRAULIC CONTROL UNIT) - OPERATION - HYDRAULIC CIRCUITS AND VALVES).

DESCRIPTION - MK25E

On Normal Launch production vehicles (which are equipped with the MK25e ABS), the hydraulic control unit (HCU) is mounted to the ABM as part of the ICU. The HCU controls the flow of brake fluid to the brakes using a series of valves and accumulators. A pump/motor is mounted on the HCU to supply build pressure to the brakes during an ABS stop.

VALVES AND SOLENOIDS

The valve block contains four inlet valves and four outlet solenoid valves. The inlet valves are spring-loaded in the open position and the outlet valves are spring-loaded in the closed position during normal braking. The fluid is allowed to flow from the master cylinder to the wheel brakes.

During an ABS stop, these valves cycle to maintain the proper slip ratio for each wheel. The inlet valve closes preventing further pressure increase and the outlet valve opens to provide a path from the wheel brake to the HCU accumulators and pump/motor. This releases (decays) pressure from the wheel brake, thus releasing the wheel from excessive slippage. Once the wheel is no longer slipping, the outlet valve is closed and the inlet valve is opened to reapply (build) pressure.

If the ABS includes the traction control feature, there are four other valves in the HCU. Two traction control (TC) valves, mounted in the HCU valve block, are normally in the open position and close only when the traction control is applied. There are also two shuttle valves which control pressure return to the master cylinder under ABS and traction control conditions.

These TC valves are used to isolate the rear (non-driving) wheels of the vehicle from the hydraulic pressure that the HCU pump/motor is sending to the front (driving) wheels when traction control is being applied. The rear brakes need to be isolated from the master cylinder when traction control is being applied so the rear wheels do not drag.

HYDRAULIC CONTROL UNIT (HCU) (Continued)

BRAKE FLUID ACCUMULATORS

There are two fluid accumulators in the HCU: one for the primary hydraulic circuit, and one for the secondary hydraulic circuit. Each hydraulic circuit uses a 3 cc accumulator.

The fluid accumulators temporarily store brake fluid that is removed from the wheel brakes during an ABS cycle. This stored fluid is used by the pump/motor to provide build pressure for the brake hydraulic system. When the antilock stop is complete, the accumulators are drained by the pump/motor.

There are two noise dampening chambers in the HCU on this vehicle equipped with traction control.

PUMP/MOTOR

There are two pump assemblies in the HCU: one for the primary hydraulic circuit, and one for the secondary hydraulic circuit. Both pumps are driven by a common electric motor. This DC-type motor is integral to the HCU and is controlled by the ABM.

The pump/motor provides the extra amount of brake fluid needed during antilock braking. Brake fluid is released to the accumulators when the outlet valve is opened during an antilock stop. The pump mechanism consists of two opposing pistons operated by an eccentric camshaft. In operation, these pistons are used to purge fluid from the accumulators back into the master cylinder circuits. When the antilock stop is complete, the pump/motor drains the accumulators.

The pump motor is also used to build pressure when the system goes into traction control mode.

The ABM may turn on the pump/motor when an antilock stop is detected. The pump/motor continues to run during the antilock stop and is turned off after the stop is complete. Under some conditions, the pump/motor runs to drain the accumulators during the next drive-off.

The pump/motor is not a serviceable item; if it requires replacement, the HCU must be replaced.

For more information, (Refer to 5 - BRAKES/HYDRAULIC/MECHANICAL/HCU (HYDRAULIC CONTROL UNIT) - OPERATION - HYDRAULIC CIRCUITS AND VALVES).

OPERATION - HYDRAULIC CIRCUITS AND VALVES

NOTE: The following applies for both MK20e and MK25e ABS.

The hydraulic fluid control valves within the HCU control the flow of pressurized brake fluid to the wheel brakes during the different modes of ABS braking and traction control. The following paragraphs explain how this works. **For purposes of explanation only, the following diagrams show only one hydraulic circuit, the Right Front wheel braking circuit.**

NORMAL BRAKING HYDRAULIC CIRCUIT AND SOLENOID VALVE FUNCTION (ABS WITHOUT TRACTION CONTROL)

The hydraulic diagram shows the vehicle in the normal braking mode of the base brake hydraulic system (Fig. 14). The diagram shows no wheel spin or slip occurring relative to the speed of the vehicle. The driver is applying the brake pedal which builds pressure in the brake hydraulic system to engage the brakes and stop the vehicle.

9 - FROM MASTER CYLINDER
10 - NOISE DAMPER CHAMBER

HYDRAULIC CONTROL UNIT (HCU) (Continued)

ABS HYDRAULIC CIRCUIT AND SOLENOID VALVE FUNCTION (ABS WITHOUT TRACTION CONTROL)

The hydraulic diagram shows the vehicle in the ABS braking mode (Fig. 15). The diagram shows one wheel is slipping because the driver is attempting to stop the vehicle at a faster rate than is allowed by the surface on which the tires are riding.

- The normally open and normally closed valves modulate (build/decay) the brake hydraulic pressure as required.
- The pump/motor is switched on so that the brake fluid from the low pressure accumulators is returned to the master cylinder circuits.
- The brake fluid is routed to either the master cylinder or the wheel brake depending on the position of the normally open valve.

12 - PUMP INTERSTAGE PRESSURE
13 - NOISE DAMPER CHAMBER

HYDRAULIC CONTROL UNIT (HCU) (Continued)

NORMAL BRAKING HYDRAULIC CIRCUIT, SOLENOID VALVE, AND SHUTTLE VALVE FUNCTION (ABS WITH TRACTION CONTROL)

The hydraulic diagram shows a vehicle with traction control in the normal braking mode (Fig. 16). The diagram shows no wheel spin or slip occurring relative to the speed of the vehicle. The driver is applying the brake pedal which builds pressure in the brake hydraulic system to engage the brakes and stop the vehicle. The hydraulic shuttle valve closes with every brake pedal application so pressure is not created at the inlet to the pump/motor.

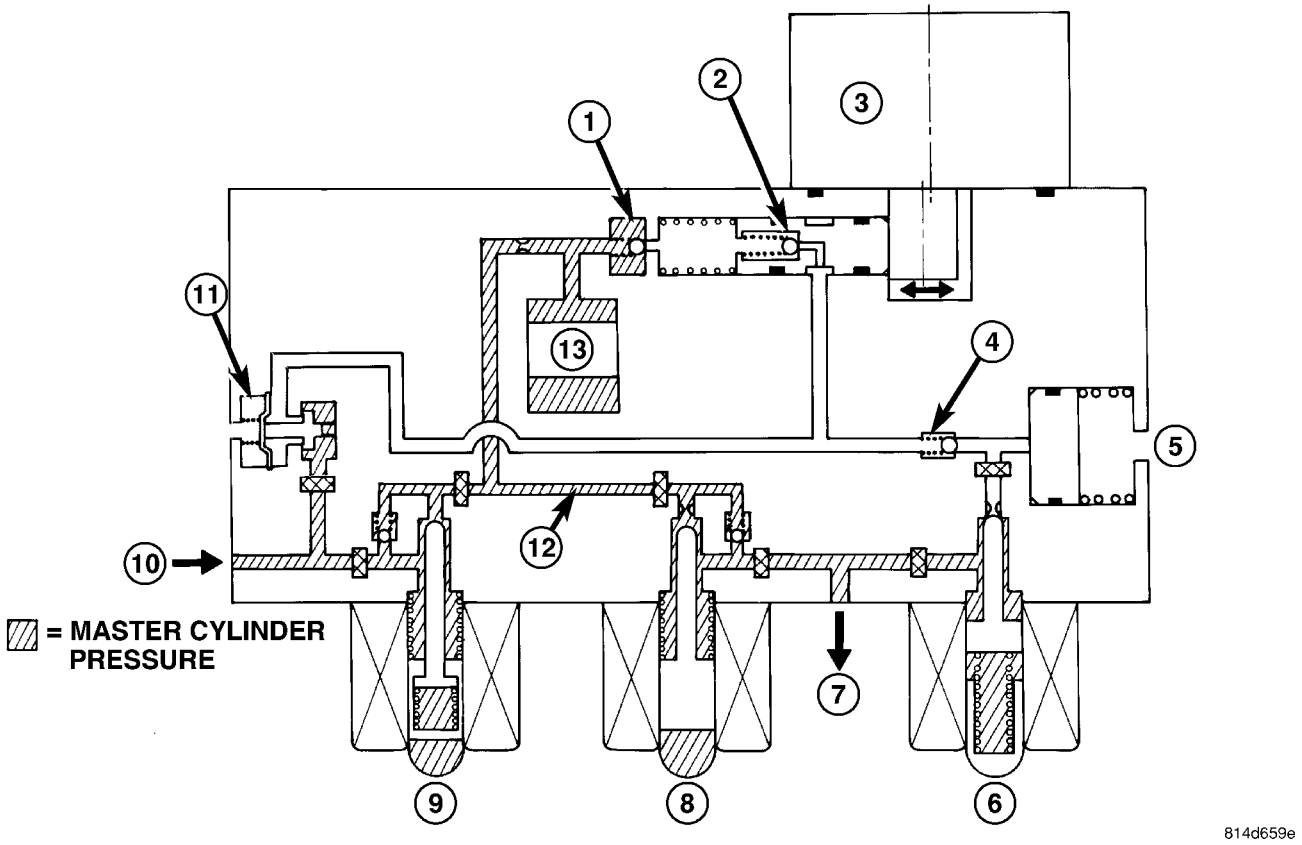

Fig. 16 Hydraulic Circuit - Normal Braking Mode (With Traction Control)

12 - MASTER CYLINDER PRESSURE
13 - NOISE DAMPER CHAMBER

HYDRAULIC CONTROL UNIT (HCU) (Continued)

ABS BRAKING HYDRAULIC CIRCUIT, SOLENOID VALVE, AND SHUTTLE VALVE FUNCTION (ABS WITH TRACTION CONTROL)

The hydraulic diagram shows the vehicle in the ABS braking mode (Fig. 17). The diagram shows one wheel is slipping because the driver is attempting to stop the vehicle at a faster rate than is allowed by the surface on which the tires are riding.

- The hydraulic shuttle valve closes upon brake application so that the pump/motor cannot siphon brake fluid from the master cylinder.
- The normally open and normally closed valves modulate (build/decay) the brake hydraulic pressure as required.
- The pump/motor is switched on so that the brake fluid from the low pressure accumulators is returned to the master cylinder circuits.
- The brake fluid is routed to either the master cylinder or the wheel brake depending on the position of the normally open valve.

ABS TRACTION CONTROL HYDRAULIC CIRCUIT, SOLENOID VALVE, AND SHUTTLE VALVE FUNCTION (ABS WITH TRACTION CONTROL)

The hydraulic diagram shows the vehicle in the traction control (TC) mode (Fig. 18). The diagram shows a drive wheel is spinning and brake pressure is required to reduce its speed.

- The normally open TC (ASR) valve is energized to isolate the brake fluid being pumped from the master cylinder and to isolate the driven wheel.
- The normally open TC (ASR) valve bypasses the pump output back to the master cylinder at a fixed pressure setting.
- The normally open and normally closed valves modulate (build/decay) the brake pressure as required to the spinning wheel.

INTEGRATED CONTROL UNIT (ICU) - MK20E

DESCRIPTION

The hydraulic control unit (HCU) and the controller antilock brake (CAB) used with this antilock brake system are combined (integrated) into one unit, which is called the integrated control unit (ICU) (Fig. 19). The ICU is located on the driver's side of the vehicle, below the master cylinder (Fig. 20).

Two different ICU's (HCU and CAB) are used on this vehicle depending on whether or not the vehicle is equipped with traction control. The HCU on a vehicle equipped with traction control has a valve block that is approximately one inch longer than a HCU on a vehicle that is equipped with ABS only.

The ABS-only ICU consists of the following components: the CAB, eight (build/decay) solenoid valves (four inlet valves and four outlet valves), valve block, fluid accumulators, a pump, and an electric motor.

The ABS with traction control ICU consists of the following components: the CAB, eight (build/decay) solenoid valves (four inlet valves and four outlet valves), two traction control solenoid valves, two hydraulic shuttle valves, valve block, fluid accumulators, a pump, and an electric pump/motor.

The replaceable components of the ICU are the HCU and the CAB. No attempt should be made to service any components of the HCU or CAB.

For additional information on the CAB, (Refer to 8 - ELECTRICAL/ELECTRONIC CONTROL MODULES/CONTROLLER ANTILOCK BRAKE - DESCRIPTION). For additional information on the HCU, (Refer to 5 - BRAKES - ABS/HYDRAULIC/MECHANICAL/HCU (HYDRAULIC CONTROL UNIT) - DESCRIPTION).

2 - HCU
3 - PUMP/MOTOR WIRING CONNECTOR
4 - CAB

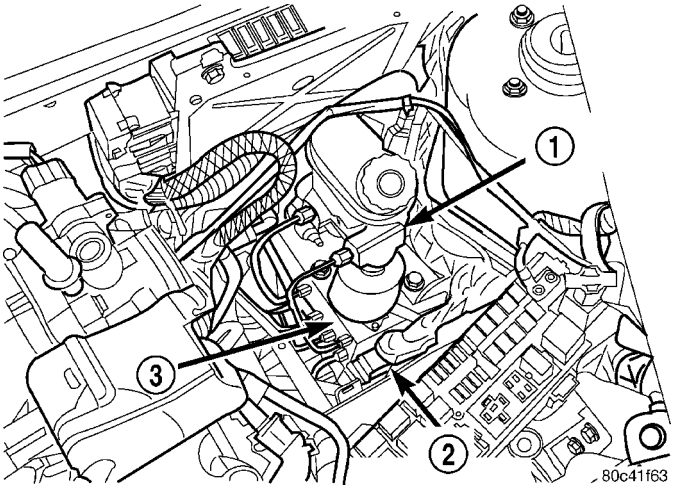

Fig. 20 Master Cylinder And ICU

1 - MASTER CYLINDER
2 - CAB CONNECTOR
3 - ICU

OPERATION

For information of the ICU, refer to these individual components of the ICU:

- CONTROLLER ANTILOCK BRAKE (CAB) (Refer to 8 - ELECTRICAL/ELECTRONIC CONTROL MODULES/CONTROLLER ANTILOCK BRAKE - OPERATION)
- HYDRAULIC CONTROL UNIT (HCU) (Refer to 5 - BRAKES - ABS/HYDRAULIC/MECHANICAL/HCU (HYDRAULIC CONTROL UNIT) - OPERATION)

REMOVAL

NOTE: If servicing the controller antilock brake (CAB) only, the CAB can be serviced with the ICU mounted in the vehicle. (Refer to 8 - ELECTRICAL/ELECTRONIC CONTROL MODULES/CONTROLLER ANTILOCK BRAKE - REMOVAL)

NOTE: Before proceeding, (Refer to 5 - BRAKES - WARNING) (Refer to 5 - BRAKES - CAUTION).

CAUTION: The vacuum in the power brake booster must be pumped down before removing the master cylinder to prevent the booster from sucking in any contamination. This can be done by pumping the brake pedal while the engine is not running until a firm brake pedal is achieved.

(1) With the engine not running, pump the brake pedal 4-5 strokes until the pedal feel is firm.

(2) Unclip the air cleaner cover (two clips) and move the cover aside.

(3) Remove the air cleaner housing by pulling straight up.

(4) Disconnect the negative (ground) cable from the battery and isolate the cable.

(5) Unlatch the power distribution center, lift it up, and move it to the side.

(6) Remove the vehicle wiring harness connector from brake fluid level switch in master cylinder brake fluid reservoir (Fig. 21).

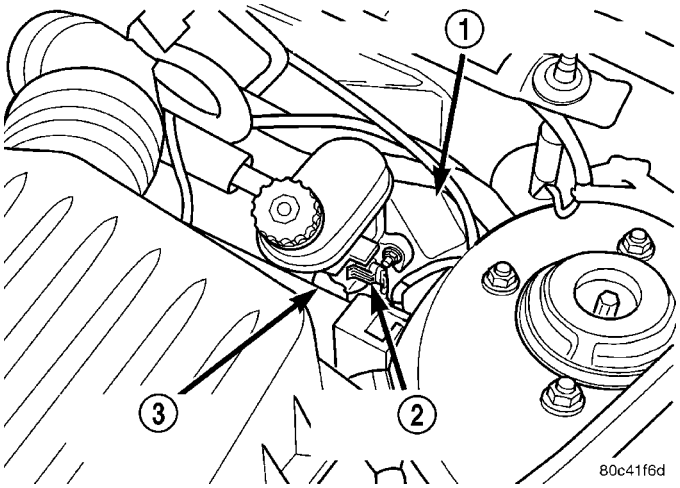

Fig. 21 Master Cylinder

1 - POWER BRAKE BOOSTER
2 - BRAKE FLUID LEVEL SWITCH
3 - MASTER CYLINDER

INTEGRATED CONTROL UNIT (ICU) - MK20E (Continued)

(7) Tag the brake tubes coming from the master cylinder as primary and secondary (Fig. 22). This is done to avoid mix-up once the tubes are removed from the vehicle.

(8) Disconnect the two brake tubes from the master cylinder primary and secondary ports (Fig. 22). Install plugs at all of the open brake tube outlets on the master cylinder.

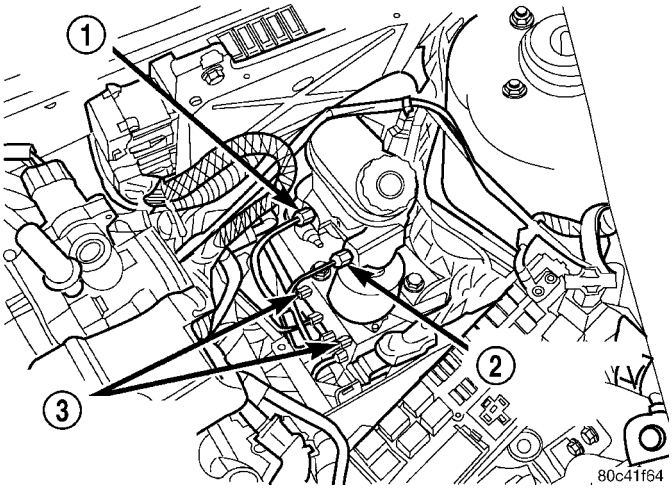

Fig. 22 Primary and Secondary Brake Tubes

1 - PRIMARY BRAKE TUBE
2 - SECONDARY BRAKE TUBE
3 - BRAKE TUBES FROM MASTER CYLINDER

(9) Disconnect and remove the primary and secondary brake tubes coming from the master cylinder at the ICU hydraulic control unit (HCU) (Fig. 22).

(10) Clean the area around where the master cylinder attaches to the power brake booster using a suitable brake cleaner such as Mopar® Brake Parts Cleaner or equivalent.

(11) Remove the two nuts attaching the master cylinder to the power brake booster.

(12) Slide the master cylinder straight out of the power brake booster.

(13) Disconnect the brake tubes going to each individual brake at the HCU (Fig. 23).

(14) Disconnect the 24-way connector from the controller antilock brake (CAB) mounted on the integrated control unit (ICU) and move it out of the way (Fig. 23). The connector is disconnected by pulling outward on the connector lock. This will unlock and raise the 24-way connector out of the socket on the CAB.

(15) Remove the 3 bolts attaching the ICU to its mounting bracket (Fig. 23).

(16) Remove the ICU from the vehicle.

(17) To separate the CAB from the HCU, (Refer to 5 - BRAKES/HYDRAULIC/MECHANICAL/ICU (INTEGRATED CONTROL UNIT) - DISASSEMBLY).

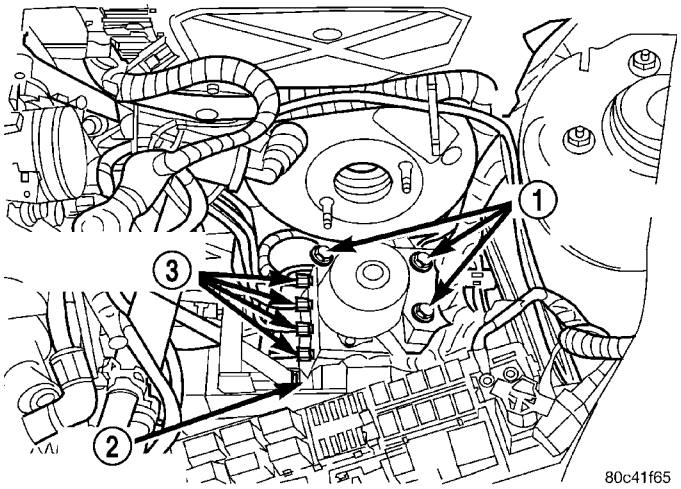

Fig. 23 ICU Connections

1 - ICU MOUNTING BOLTS
2 - CAB CONNECTOR
3 - BRAKE TUBES TO BRAKES

DISASSEMBLY - ICU

(1) Disconnect the pump/motor wiring harness from the CAB (Fig. 24).

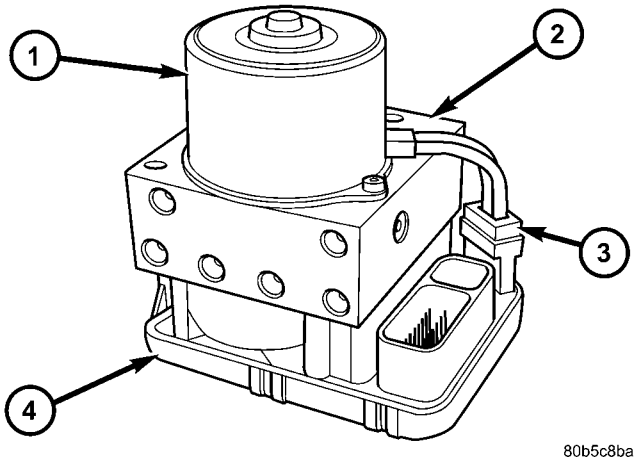

Fig. 24 Integrated Control Unit (ICU)

1 - PUMP/MOTOR
2 - HCU
3 - PUMP/MOTOR WIRING CONNECTOR
4 - CAB

(2) Remove the 4 bolts attaching the CAB to the HCU (Fig. 25).

(3) Remove the CAB from the HCU (Fig. 26).

ASSEMBLY - ICU

(1) Install the CAB on the HCU (Fig. 26).

(2) Install the 4 bolts mounting the CAB to the HCU (Fig. 25). Tighten the CAB mounting bolts to a torque of 2 N·m (17 in. lbs.).

(3) Plug the pump/motor wiring harness into the CAB (Fig. 24).

1 - CAB
2 - HCU VALVE BLOCK
3 - MOUNTING BOLTS

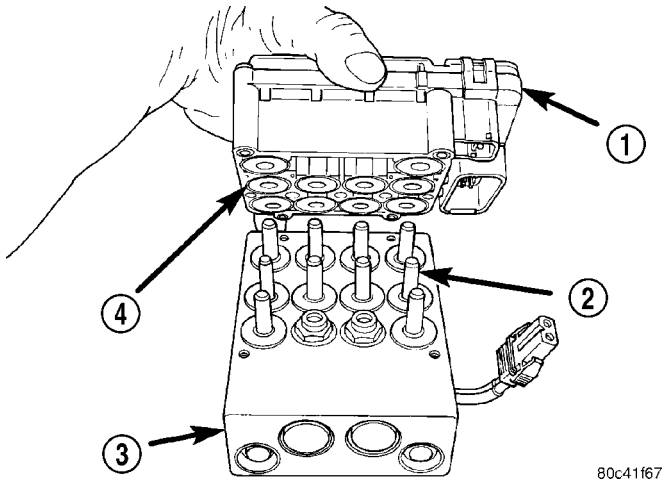

Fig. 26 Remove/Install CAB

1 - CAB
2 - VALVES
3 - HCU VALVE BLOCK
4 - SOLENOIDS

(4) Install the ICU in the vehicle. (Refer to 5 - BRAKES/HYDRAULIC/MECHANICAL/ICU (INTEGRATED CONTROL UNIT) - INSTALLATION)

INSTALLATION

(1) Install the ICU onto its mounting bracket.

(2) Install the 3 bolts attaching the ICU to the mounting bracket (Fig. 23). Tighten the 3 mounting bolts to a torque of 11 N·m (97 in. lbs.)

CAUTION: Before installing the 24-way connector in the CAB, be sure the seal is properly installed in the connector.

(3) Install the 24-way connector into the socket of the CAB as follows:

- Position the 24-way connector in the socket of the CAB and carefully push it down as far as possible (Fig. 23).
- When the connector is fully seated into the CAB socket, push the connector lock inward. This pulls the connector into the socket of the CAB and locks it in the installed position.

(4) Install the four brake tubes going to the brakes into their respective outlet ports on the ICU HCU (Fig. 23). Using a crow foot on a torque wrench, tighten the four brake tube nuts to a torque of 17 N·m (145 in. lbs.).

(5) Wipe the face of the power brake booster clean where the master cylinder seal comes in contact when it's installed. Do not get any cleaner or debris inside the booster.

(6) Position the master cylinder on the studs of the power brake booster, aligning the push rod of the power brake booster with master cylinder piston push rod. Carefully push the master cylinder onto the studs until it contacts the face of the booster.

(7) Install the two master cylinder mounting nuts and tighten each to a torque of 18 N·m (160 in. lbs.).

NOTE: When installing the brake tubes from the master cylinder on the HCU, the brake tube with the small tube nut is to be installed in the forward-most port on the HCU with the small end going toward the master cylinder secondary port.

(8) Install the primary and secondary brake tubes from the master cylinder onto the HCU (Fig. 22). Do not completely tighten the primary and secondary tubes at this time.

(9) Connect the two brake tubes to the master cylinder primary and secondary ports (Fig. 22).

(10) Using a crow foot on a torque wrench, tighten the primary and secondary brake tube nuts at both the master cylinder and HCU to a torque of 17 N·m (145 in. lbs.).

(11) Connect the brake fluid level switch wiring connector.

(12) Install the power distribution center.

(13) Connect the negative (ground) cable on the battery.

(14) Install the air cleaner housing.

(15) Install the air cleaner cover.

(16) Hook up the DRBIII® to initialize the new CAB.

(17) Fill the master cylinder to the proper fill level and bleed the base and ABS hydraulic systems. (Refer to 5 - BRAKES - ABS - STANDARD PROCEDURE)

(18) Road test the vehicle to ensure proper operation of the base and antilock brake systems.

INTEGRATED CONTROL UNIT (ICU) - MK25E

DESCRIPTION

The Hydraulic Control Unit (HCU) and the Antilock Brake Module (ABM) used with this antilock brake system are combined (integrated) into one unit, which is called the Integrated Control Unit (ICU) (Fig. 27). The ICU is located in the engine compartment, mounted to the left side body frame rail (Fig. 28) right below the master cylinder (on left-hand-drive vehicles).

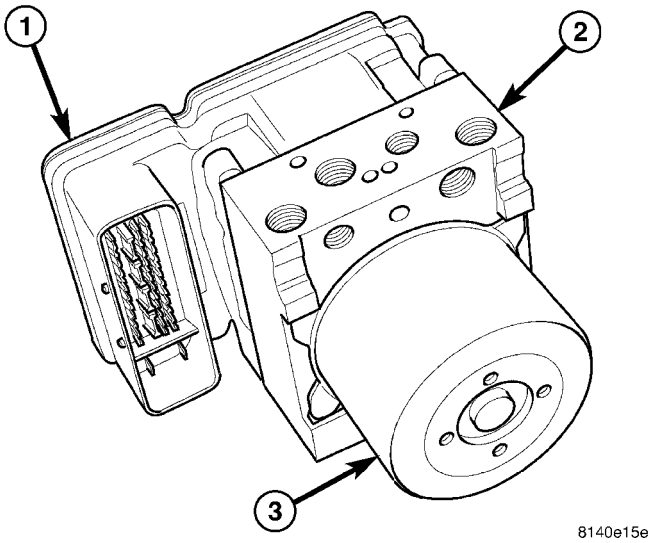

Fig. 27 Integrated Control Unit

1 - ANTILOCK BRAKE MODULE (ABM)
2 - HYDRAULIC CONTROL UNIT (HCU)
3 - PUMP/MOTOR

Two different ICU's are used on this vehicle depending on whether or not the vehicle is equipped with traction control. The HCU on a vehicle equipped with traction control has a valve block that is approximately one inch longer than a HCU on a vehicle that is equipped with ABS only.

The ABS-only ICU consists of the following components: the ABM, eight (build/decay) solenoid valves (four inlet valves and four outlet valves), valve block, fluid accumulators, a pump, and an electric motor.

The ABS with traction control ICU consists of the following components: the ABM, eight (build/decay) solenoid valves (four inlet valves and four outlet valves), two traction control solenoid valves, two hydraulic shuttle valves, valve block, fluid accumulators, a pump, and an electric pump/motor.

The replaceable components of the ICU are the HCU and the ABM. No attempt should be made to service any components of the HCU or ABM.

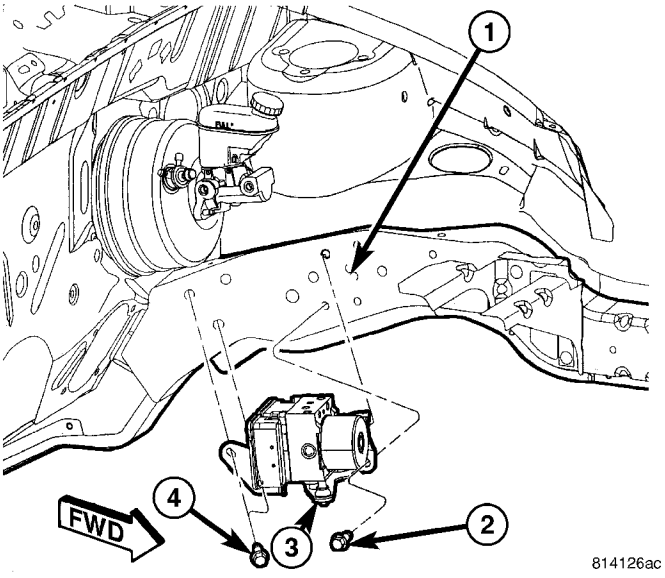

Fig. 28 ICU Mounting

1 - BODY FRAME RAIL

3 - ICU MOUNTING BRACKET
4 - REAR MOUNTING SCREWS

For additional information on the ABM, (Refer to 8 - ELECTRICAL/ELECTRONIC CONTROL MODULES/ANTILOCK BRAKE MODULE - DESCRIPTION). For additional information on the HCU, (Refer to 5 - BRAKES - ABS/HYDRAULIC/MECHANICAL/HCU (HYDRAULIC CONTROL UNIT) - DESCRIPTION).

OPERATION

For information of the ICU, refer to these individual components of the ICU:

- ANTILOCK BRAKE MODULE (ABM) (Refer to 8 - ELECTRICAL/ELECTRONIC CONTROL MODULES/ANTILOCK BRAKE MODULE - DESCRIPTION)
- HYDRAULIC CONTROL UNIT (HCU) (Refer to 5 - BRAKES - ABS/HYDRAULIC/MECHANICAL/HCU (HYDRAULIC CONTROL UNIT) - OPERATION)

REMOVAL

NOTE: Before proceeding, (Refer to 5 - BRAKES - WARNING) (Refer to 5 - BRAKES - CAUTION).

(1) Unclip the air cleaner cover (two clips) and move the cover aside.

(2) Remove the air cleaner housing by pulling it straight up.

(3) Remove the battery. (Refer to 8 - ELECTRICAL/BATTERY SYSTEM/BATTERY - REMOVAL)

INTEGRATED CONTROL UNIT (ICU) - MK25E (Continued)

(4) Disconnect the vehicle wiring harness connector from the brake fluid level switch in the master cylinder brake fluid reservoir (Fig. 29).

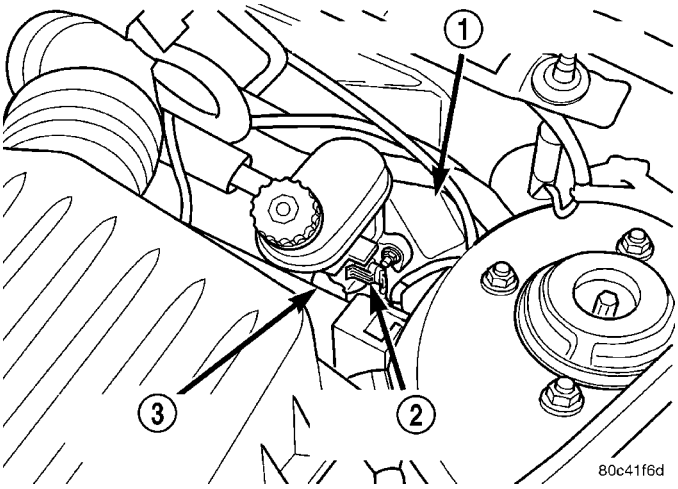

Fig. 29 Master Cylinder

1 - POWER BRAKE BOOSTER
2 - BRAKE FLUID LEVEL SWITCH
3 - MASTER CYLINDER

(5) Remove the two bolts fastening the power distribution center mounting bracket in place (Fig. 30) (Fig. 31).

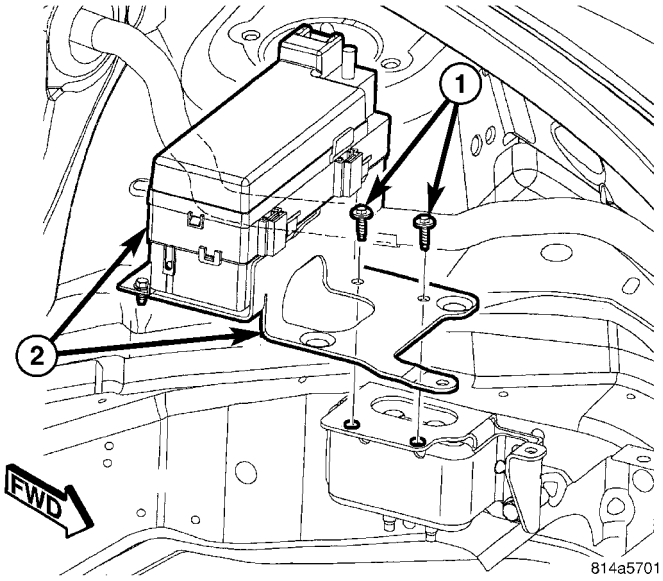

Fig. 30 PDC With Bracket Mounting - Non-Turbo Engine

1 - MOUNTING BOLTS

(11) Raise and support the vehicle. (Refer to LUBRICATION & MAINTENANCE/HOISTING - STANDARD PROCEDURE)

(12) Remove the two rear mounting screws attaching the ICU mounting bracket to the body (Fig. 37).

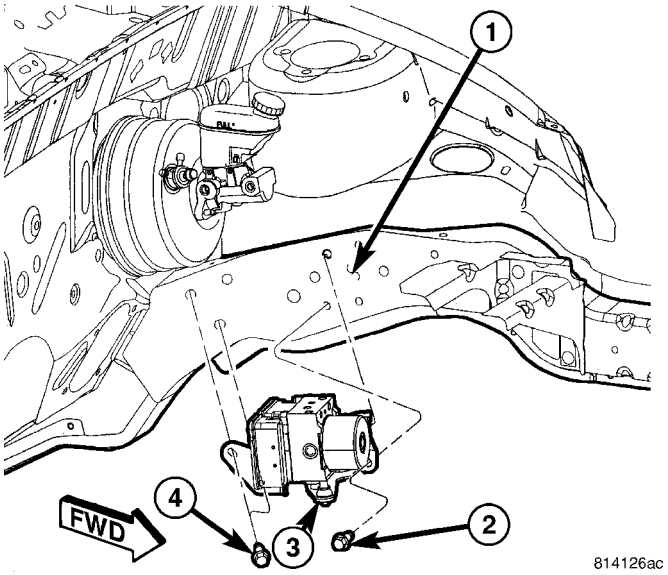

Fig. 37 ICU Mounting

1 - BODY FRAME RAIL
2 - FRONT MOUNTING SCREW
3 - ICU MOUNTING BRACKET
4 - REAR MOUNTING SCREWS

(13) Lower the vehicle.

(14) Remove the front mounting screw attaching the ICU mounting bracket to the body (Fig. 37).

(15) Lift the ICU and mounting bracket from the vehicle.

(16) To separate the ABM from the HCU, (Refer to 5 - BRAKES/HYDRAULIC/MECHANICAL/ICU (INTEGRATED CONTROL UNIT) - DISASSEMBLY).

DISASSEMBLY

(1) If the mounting bracket needs to be removed from the ICU, remove the single mounting bolt (Fig. 38), then slide the ICU's mounting pins out of the grommets in the bracket. Remove the mounting pins from the ICU as necessary.

(2) If not equipped with traction control, remove the three screws attaching the ABM to the HCU (Fig. 39).

(3) If equipped with traction control, remove the four screws attaching the ABM to the HCU (Fig. 40).

(4) Separate the ABM from the HCU (Fig. 41).

ASSEMBLY

(1) Clean any debris off the mating surfaces of the HCU and ABM.

Tighten the mounting screws to 2 N·m (17 in. lbs.) torque.

(6) If the mounting bracket needs to be installed, install the mounting pins in the ICU as necessary and tighten to 11 N·m (97 in. lbs.) torque. Insert the mounting pins into the grommets mounted in the bracket, then install the single mounting bolt (Fig. 38). Tighten the mounting bolt to 11 N·m (97 in. lbs.) torque.

INTEGRATED CONTROL UNIT (ICU) - MK25E (Continued)

(7) Install the ICU in the vehicle. (Refer to 5 - BRAKES/HYDRAULIC/MECHANICAL/ICU (INTEGRATED CONTROL UNIT) - INSTALLATION)

INSTALLATION

(1) Place the ICU and mounting bracket into the engine compartment, inserting bracket hooks into hanger holes in body frame rail (Fig. 37).

(2) Install the front mounting screw attaching the ICU mounting bracket to the body (Fig. 37). **Do not tighten screw at this time.**

(3) Raise and support the vehicle. (Refer to LUBRICATION & MAINTENANCE/HOISTING - STANDARD PROCEDURE)

(4) Install the two rear mounting screws attaching the ICU mounting bracket to the body (Fig. 37). Tighten both screws to 23 N·m (200 in. lbs.) torque.

(5) Lower the vehicle.

(6) Tighten the front mounting screw attaching the ICU mounting bracket to the body (Fig. 37) to 23 N·m (200 in. lbs.) torque.

CAUTION: Before installing the 47-way connector on the ABM, be sure the seal is properly installed in the connector.

(7) Install the 47-way wiring connector into the socket of the ABM and close the cover (Fig. 36), locking the connector in place.

(8) Install the four chassis brake tubes going to the wheel brakes into their respective outlet ports on the ICU HCU (Fig. 32) (Fig. 33) (Fig. 34). Using a crow foot wrench on a torque wrench, tighten the four tube nuts to 17 N·m (145 in. lbs.) torque.

(9) Install the primary and secondary brake tubes from the master cylinder into the HCU ports (Fig. 32) (Fig. 33). Using a crow foot wrench on a torque wrench, tighten the tube nuts to 17 N·m (145 in. lbs.) torque.

(10) Position the power distribution center and bracket back into place and install the mounting bolts (Fig. 30) (Fig. 31).

(11) Connect the wiring connector to the brake fluid level switch (Fig. 29).

(12) Install the battery. (Refer to 8 - ELECTRICAL/BATTERY SYSTEM/BATTERY - INSTALLATION)

(13) Install the air cleaner housing.

(14) Install the air cleaner cover.

(15) Hook up the scan tool to initialize the new ABM. Clear any faults and perform verification test.

(16) Fill the master cylinder to the proper fill level and bleed the base and ABS hydraulic systems. (Refer to 5 - BRAKES - ABS - STANDARD PROCEDURE)

(17) Road test the vehicle to ensure proper operation of the base and antilock brake systems.

CLUTCH

DESCRIPTION

The typical clutch hydraulic system consists of a clutch master cylinder, slave cylinder, and an interconnecting fluid line (Fig. 1) (Fig. 2). Clutch hydraulic fluid is supplied by the brake system via the brake master cylinder reservoir. LHD models have an adjustable pedal pushrod.

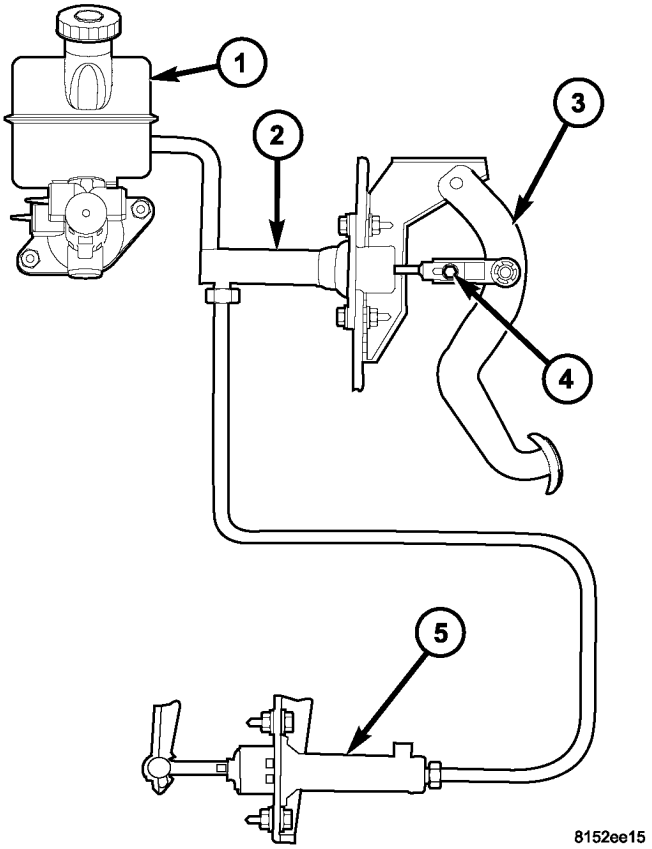

Fig. 1 LHD Clutch Hydraulic System—Typical

1 - BRAKE MASTER CYLINDER RESERVOIR
2 - CLUTCH MASTER CYLINDER
3 - PEDAL ASSEMBLY
4 - ADJUSTMENT SCREW
5 - SLAVE CYLINDER

FLUID

CAUTION: Never use any type of petroleum-based fluid (engine oil, transmission oil, power steering fluid, etc.) in the clutch hydraulic system. Use of such fluids will result in master/slave cylinder seal damage, and cause a failure of the hydraulic clutch release system.

NOTE: Under normal operating conditions, the clutch hydraulic system does not require additional fluid for the life of the vehicle. Since the clutch shares the brake reservoir, the fluid level will be maintained whenever the brake system is checked.

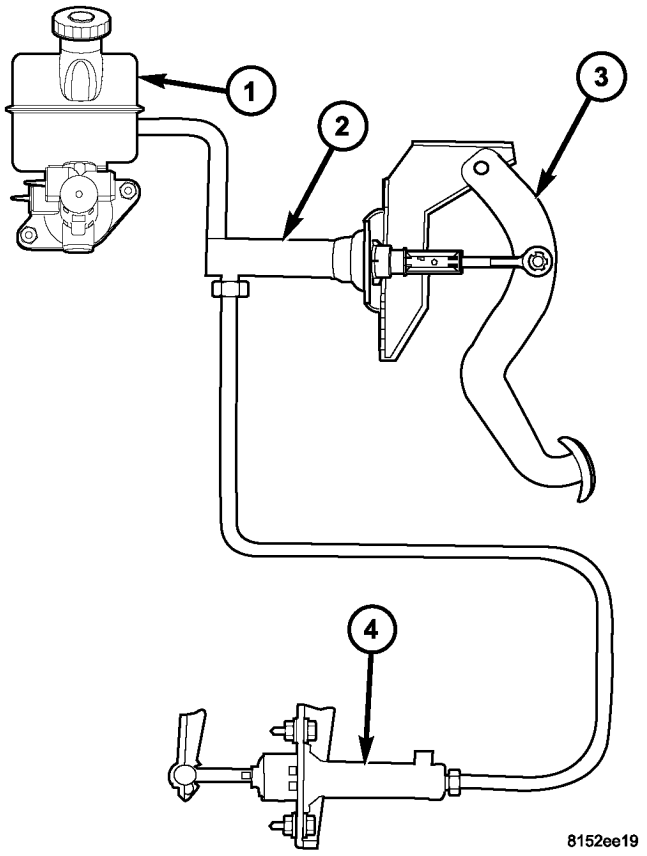

Fig. 2 RHD Clutch Hydraulic System—Typical

1 - BRAKE MASTER CYLINDER RESERVOIR
2 - MASTER CYLINDER
3 - PEDAL ASSEMBLY
4 - SLAVE CYLINDER

The fluid required for use in the clutch hydraulic system is brake fluid conforming to DOT 3 specifications and J1703 standards. No other type of fluid is recommended or approved for use in the clutch hydraulic system. use only Mopar® brake fluid or equivalent from a tightly sealed container.

OPERATION

T350-Equipped Models

The clutch hydraulic system is responsible for engaging and disengaging the clutch. Depressing the clutch pedal develops fluid pressure in the clutch master cylinder. This pressure is transmitted to the slave cylinder through a connecting line. In turn, the slave cylinder operates the clutch release lever (Fig. 1) (Fig. 2).

Slave cylinder spring force causes the release lever to hold the release bearing in contact with the diaphragm spring, also known as bearing preload. During a clutch pedal actuation, the hydraulic fluid

CLUTCH (Continued)

pressure applies additional force to the release lever. As additional force is applied, the bearing presses the diaphragm spring fingers inward on the fulcrums. This action moves the pressure plate rearward, relieving clamp force on the disc.

G288-Equipped Models

The clutch hydraulic system is responsible for engaging and disengaging the clutch. Depressing the clutch pedal develops fluid pressure in the clutch master cylinder. This pressure is transmitted to the slave cylinder through a connecting line.

Slave cylinder force transmits through the integral release bearing, which is in contact with the pressure plate diaphragm spring. As additional force is applied, the bearing depresses the diaphragm spring fingers inward on the fulcrums. The action moves the pressure plate rearward, relieving clamping force on the clutch disc.

DIAGNOSIS AND TESTING

DIAGNOSIS AND TESTING—CLUTCH SYSTEM DIAGNOSIS

Clutch problem diagnosis will generally require a road test to determine the type of fault. Component inspection will then determine the problem after road testing.

Drive the vehicle at normal speeds during road test. Shift the transaxle through all gear ranges and observe clutch action. If chatter, grab, slip, or improper release is experienced, remove and inspect the clutch components. If the problem is noise or hard shifting, further diagnosis may be needed. The transaxle or other driveline components may actually be at fault.

SERVICE DIAGNOSIS - CLUTCH GRAB/CHATTER

CONDITION	POSSIBLE CAUSES	CORRECTION
CLUTCH DISC FACING COVERED WITH OIL OR GREASE	Oil leak at engine rear main or transaxle input shaft seal.	2.4L - Correct leak and replace modular clutch assembly. 1.6L/Diesel/Turbo - Clean pressure plate, flywheel, and replace clutch disc.
	Too much grease applied to splines of disc and input shaft.	Apply lighter coating of grease to splines.
NO FAULT FOUND WITH CLUTCH COMPONENTS	Problem actually related to suspension or driveline component.	Further diagnosis required. Check engine/transmission mounts, suspension attaching parts and other driveline components as needed.
	Engine related problems.	Check EFI and ignition systems.
PARTIAL ENGAGEMENT OF CLUTCH DISC	Clutch cover, spring, or release fingers bent, distorted (rough handling, improper assembly).	Replace clutch assembly.
	Clutch disc damaged or distorted.	Replace clutch assembly.
	Clutch misalignment.	2.4L and Turbo - Verify modular clutch pilot plate alignment to crankshaft. Replace the modular clutch assembly if the pilot plate is loose or bent. 1.6L and Diesel - Check alignment and runout of flywheel, disc, or cover. Check clutch housing to engine dowels and dowel holes for damage. Correct as necessary.

CLUTCH (Continued)

SERVICE DIAGNOSIS - CLUTCH SLIPS

CONDITION	POSSIBLE CAUSES	CORRECTION
DISC FACING WORN OUT	Normal wear.	Replace clutch assembly.
	Driver frequently rides (slips) clutch, results in rapid wear, overheating.	Replace clutch assembly.
	Insufficient clutch cover diaphragm spring tension	Replace clutch assembly.
CLUTCH DISC FACING CONTAMINATED WITH OIL OR GREASE	Leak at rear main oil seal or transaxle input shaft seal	2.4L - Replace leaking seals. Replace clutch assembly. 1.6L/Diesel/Turbo - Replace leaking seals. Clean the pressure plate and flywheel surface and replace clutch disc.
	Excessive amount of grease applied to input shaft splines	2.4L - Apply less grease to input shaft. Replace clutch assembly. 1.6L/Diesel/Turbo - Apply less grease to input shaft. Clean the pressure plate and flywheel surface and replace clutch disc.
	Road splash, water entering housing	Seal housing. Inspect clutch assembly.
	Concentric Slave Cylinder leaking hydraulic fluid	Replace Concentric Slave Cylinder (CSC)
CLUTCH IS RUNNING PARTIALLY DISENGAGED	Release bearing sticking or binding, does not return to normal running position.	Verify that bearing is actually binding. Then, replace bearing and transmission front bearing retainer if sleeve surface is damaged.
	Clutch master cylinder pushrod not adjusted properly (LHD Models), causing high preload.	Verify that pushrod adjustment is correct (LHD Models).
	Slave cylinder binding	Replace slave cylinder
CLUTCH DISC FACINGS HAVE FRACTURED INTO SMALL PIECES	Driver performs a 5-1 downshift at vehicle speed in excess of 60 miles per hour	Alert driver to problem cause. Replace clutch assembly. Inspect slave cylinder, fork, and bearing for damage.
	Leak at rear main or transaxle input shaft seal	2.4L - Replace seal. Replace clutch assembly. 1.6L/Diesel/Turbo - Replace seal. Clean the pressure plate and flywheel surface and replace clutch disc.
	Excessive heat from slippage	Replace Clutch Assembly

CLUTCH (Continued)

SERVICE DIAGNOSIS - IMPROPER CLUTCH RELEASE

CONDITION	POSSIBLE CAUSES	CORRECTION
CLUTCH DISC BINDS ON INPUT SHAFT SPLINES	Clutch disc hub splines damaged during installation	Clean, smooth, and lubricate disc and shaft splines. Replace modular clutch assembly, or clutch disc, and/or input shaft if splines are severely damaged.
	Input shaft splines rough, damaged.	Clean input shaft splines. Then lube.
	Corrosion or rust formations on splines of input shaft and disc	Clean input shaft splines and disc splines, then lube
CLUTCH DISC RUSTED TO FLYWHEEL AND/OR PRESSURE PLATE	Occurs in vehicles stored or not driven for extended period of time. Also occurs after steam cleaning if vehicle is not used for extended period.	Replace clutch assembly.
CLUTCH WILL NOT DISENGAGE PROPERLY	Disc bent, distorted during transaxle installation	Replace clutch assembly.
	Clutch cover diaphragm spring damaged during transaxle installation	Replace clutch assembly.
	Release lever bent, loose, or damaged	Replace release lever if worn or damaged
	Air in clutch hydraulic system.	Bleed clutch hydraulic system to purge air.
	Clutch master cylinder or slave cylinder leaking	Check and replace master and/or slave cylinder
	Master cylinder adjustable pushrod loose or damaged	Inspect. Tighten adjustment fastener or replace master cylinder.
	Pushrod not retained to clutch pedal pin.	Inspect pushrod & busing. Replace as necessary.

SERVICE DIAGNOSIS - CLUTCH PEDAL NOISE

CONDITION	POSSIBLE CAUSES	CORRECTION
CLUTCH PEDAL SQUEAKS WHEN DEPRESSED TO FLOOR	Pedal bushings worn out or inadequate lubrication	Replace or lubricate bushings
	Clutch pedal return spring worn out	Lubricate or replace return spring

DIAGNOSIS AND TESTING - CLUTCH CHATTER COMPLAINTS

For all clutch chatter complaints, perform the following:

(1) Check for loose, misaligned, or broken engine and transmission mounts. If present, they should be corrected at this time. Test vehicle for chatter. If chatter is gone, there is no need to go any further.

(2) If chatter persists, check hydraulic clutch release system is functioning properly.

(3) Check for loose connections in drivetrain. Correct any problems and determine if clutch chatter complaints have been satisfied. If not:

(a) Remove transaxle.

(b) Check to see if the release bearing is sticky or binding. Replace bearing, if needed.

(c) Check linkage for excessive wear on the pivot stud and fork fingers. Replace all worn parts.

(d) Check clutch assembly for contamination (dirt, oil). Replace clutch assembly, if required.

(e) Check to see if the clutch disc hub splines are damaged. Replace with new clutch assembly, if necessary.

(f) Check input shaft splines for damage. Replace, if necessary.

(g) Check for uneven wear on clutch fingers.

CLUTCH (Continued)

(h) Check for broken clutch cover diaphragm spring fingers. Replace with new clutch assembly, if necessary.

DIAGNOSIS AND TESTING - DRIVE PLATE MISALIGNMENT

Common causes of misalignment are:

- Heat warping
- Mounting drive plate on a dirty crankshaft flange
- Incorrect bolt tightening
- Improper seating on the crankshaft shoulder
- Loose crankshaft bolts

Clean the crankshaft flange before mounting the drive plate. Dirt and grease on the flange surface may misalign the flywheel, causing excessive runout. Use new bolts when mounting drive plate to crankshaft. Tighten drive plate bolts to specified torque only. Over-tightening can distort the drive plate hub causing excessive runout.

DIAGNOSIS AND TESTING - CLASH-INTO-REVERSE COMPLAINTS

All T350 manual transaxles are equipped with a reverse brake. It prevents clash when shifting into reverse, but only if the vehicle is not moving.

(1) Depress clutch pedal to floor and hold. After three seconds, shift to reverse. If clash is present, clutch has excessive spin time, and the reverse brake may not be functioning.

(2) Remove transaxle.

(3) Check the input shaft spline, clutch disc splines, and release bearing for dry rust. If present, clean rust off and apply a light coat of bearing grease to the input shaft splines. Apply grease on the input shaft splines only where the clutch disc slides. Verify that the clutch disc slides freely along the input shaft spline.

(4) Check to see if the clutch disc hub splines are damaged, and replace with new clutch assembly if required.

(5) Check the input shaft for damaged splines. Replace as necessary.

(6) Check for broken clutch cover diaphragm spring fingers.

(7) Install clutch assembly and transaxle.

STANDARD PROCEDURE—BLEEDING CLUTCH HYDRAULIC CIRCUIT

NOTE: It is necessary to bleed the clutch hydraulic release system if the system has lost an excessive amount of fluid and has ingressed air into the circuit. Air in the system typically results in a spongy pedal feel, and/or improper clutch release.

1.6/2.4L MODELS (Except Turbo)

(1) Verify fluid level in brake master cylinder. Top off with DOT 3 brake fluid as necessary. Leave cap off.

(2) Raise vehicle on hoist.

(3) Remove bleed port protective cap, and install suitable size and length of clear hose (Fig. 3) to monitor and divert fluid into suitable container.

(4) Release only the lower hydraulic tube snap ring, pull outward on tube until it stops against the second ring, opening up the bleed circuit and starting the air purge and fluid fill process (Fig. 3).

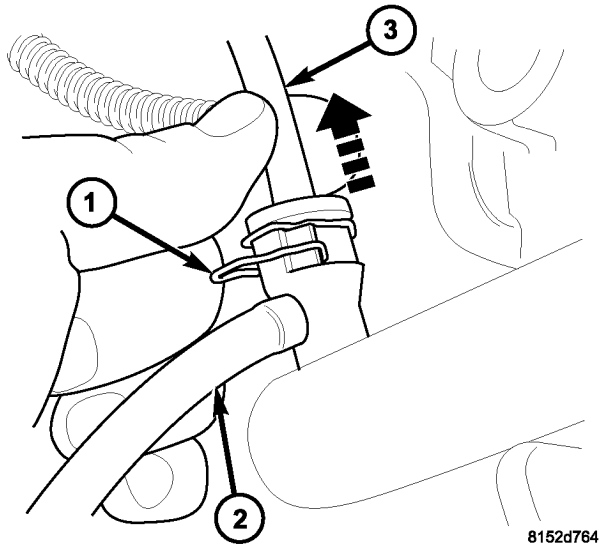

Fig. 3 Opening Hydraulic Circuit Bleed - 1.6/2.4L Models

1 - RETAINING RING
2 - CLEAR HOSE
3 - HYDRAULIC TUBE

(5) Lower vehicle, but only enough to gain access to and fill the brake master cylinder.

NOTE: Do not allow clutch master cylinder to run dry while fluid exits bleed port. If master cylinder runs dry, it is necessary to remove clutch master cylinder, position vertically (with pushrod down) for 10 seconds, and reinstall.

(6) Top off brake master cylinder fluid level while air is purged and fluid drains from bleed port. Continue this until no air bubbles are seen and a solid column of fluid exists.

CLUTCH (Continued)

(7) Close hydraulic bleed circuit. Insert hydraulic pipe fully into slave cylinder and depress retaining ring so both are closed, securing tube (Fig. 4). Remove drain hose. Pull outward to verify connection.

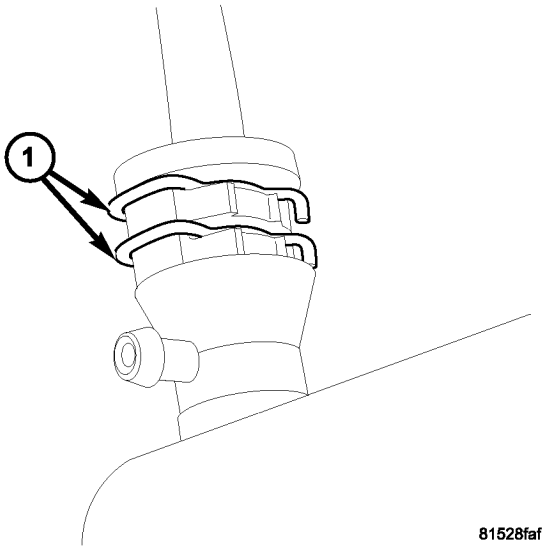

Fig. 4 Hydraulic Tube Retaining Clips

1 - RETAINER CLIPS

(8) From driver's seat, actuate clutch pedal 60–100 times.

(9) **Apply parking brake**. Start engine and verify clutch operation and pedal feel. If pedal feels fine and clutch operates as designed, stop here. If pedal still feels spongy or clutch does not fully disengage, excessive air is still trapped within the system.

(10) Verify fluid level in clutch master cylinder reservoir. Top off with DOT 3 brake fluid as necessary.

(11) Raise vehicle on hoist.

(12) Remove clutch slave cylinder assembly from the transaxle case (Fig. 5) (Fig. 6), **but do not disconnect from the system**. Allow the slave cylinder to hang, making it the lowest part of the system.

CAUTION: While slave cylinder is detached from the transaxle, DO NOT actuate the clutch master cylinder. Damage to the slave cylinder will result.

(13) Depress slave cylinder pushrod until it bottoms and then release. Repeat this at least 50 times, forcing trapped air upwards and out of the system.

(14) Re-install slave cylinder into position. **1.6L equipped models:** Torque slave cylinder to case bolt to 12 N·m (105 in. lbs.). **2.4L equipped models:** Torque slave cylinder to case bolt to 19 N·m (168 in. lbs.).

1 - SLAVE CYLINDER
2 - BOLT

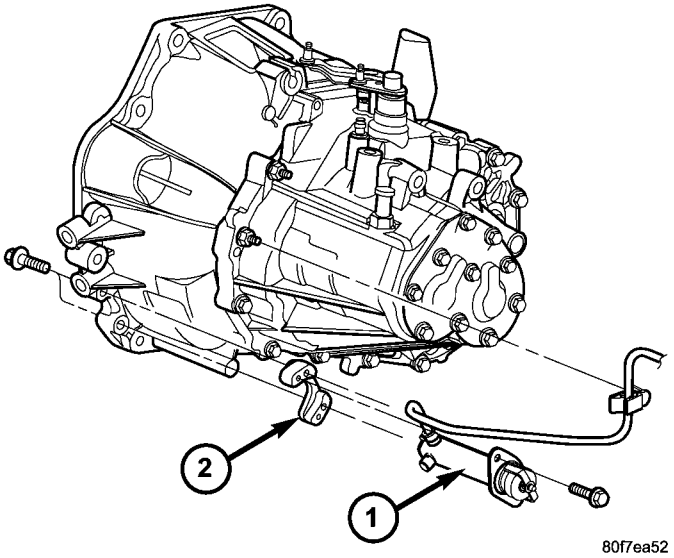

Fig. 6 Clutch Slave Cylinder at Transaxle- 2.4L

1 - SLAVE CYLINDER
2 - BRACKET

(15) Lower vehicle.

(16) Verify clutch operation. Repeat procedure if necessary.

(17) Top off brake master cylinder fluid level with DOT 3 brake fluid as necessary.

CLUTCH (Continued)

2.2L DIESEL/2.4L TURBO MODELS

(1) Verify fluid level in brake master cylinder. Top off with DOT 3 brake fluid as necessary. Leave cap off.

(2) Raise vehicle on hoist.

(3) Remove bleed port protective cap, and install suitable size and length of clear hose (Fig. 7) to monitor and divert fluid into suitable container.

(4) Release only the lower hydraulic tube snap ring, pull outward on tube until it stops against the second ring, opening up the bleed circuit and starting the air purge and fluid fill process (Fig. 7).

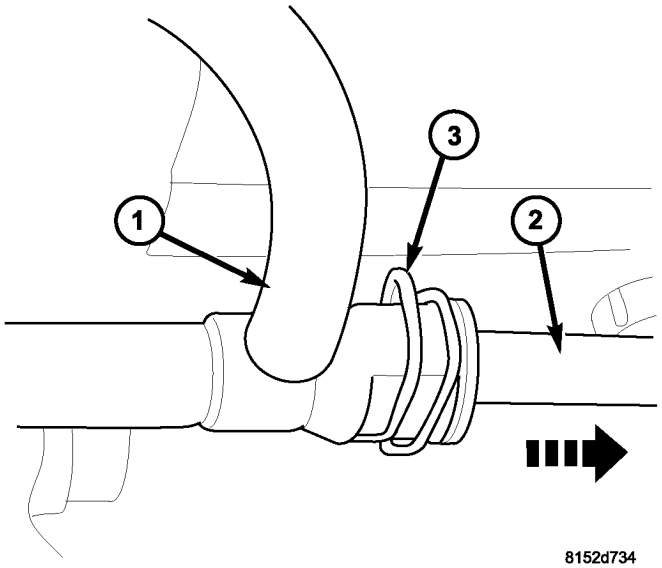

Fig. 7 Opening Hydraulic Circuit Bleed Port

1 - CLEAR HOSE
2 - HYDRAULIC TUBE
3 - RETAINER RING

(5) Lower vehicle, but only enough to gain access to and fill the brake master cylinder.

NOTE: Do not allow clutch master cylinder to run dry while fluid exits bleed port. If master cylinder runs dry, it is necessary to remove clutch master cylinder, position vertically (with pushrod down) for 10 seconds, and reinstall.

(6) Top off brake master cylinder fluid level while air is purged and fluid drains from bleed port. Continue this until no air bubbles are seen and a solid column of fluid exists.

(7) Close hydraulic bleed circuit. Insert hydraulic pipe fully into slave cylinder and depress retaining ring so both are closed, securing tube (Fig. 8). Remove drain hose. Pull outward to verify connection.

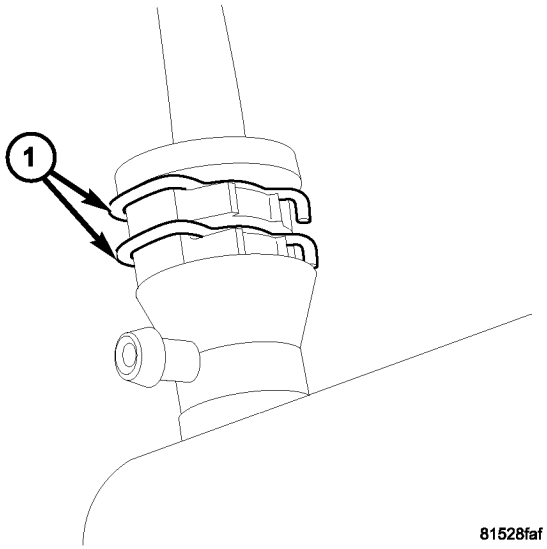

Fig. 8 Hydraulic Tube Retaining Clips

1 - RETAINER CLIPS

(8) From driver's seat, actuate clutch pedal 60–100 times.

(9) **Apply parking brake**. Start engine and verify clutch operation and pedal feel. If pedal feels fine and clutch operates as designed, stop here. If pedal still feels spongy or clutch does not fully disengage, excessive air is still trapped within the system most likely at the master cylinder.

(10) Remove clutch master cylinder body from dash panel or pedal bracket. Position cylinder body vertical (pushrod pointing down) for 10 seconds. Air bubbles will be seen escaping master cylinder.

(11) Verify clutch operation. Repeat procedure if necessary.

(12) Top off brake master cylinder fluid level with DOT 3 brake fluid as necessary.

CLUTCH DISC AND PRESSURE PLATE (Continued)

REMOVAL—2.2L TD

(1) Remove transaxle assembly. (Refer to 21 - TRANSMISSION/TRANSAXLE/MANUAL - REMOVAL)

(2) Mark position of pressure plate on flywheel with paint or a scriber for assembly reference.

(3) Loosen and remove six (6) pressure plate-to-flywheel bolts. Remove pressure plate and clutch disc (Fig. 12).

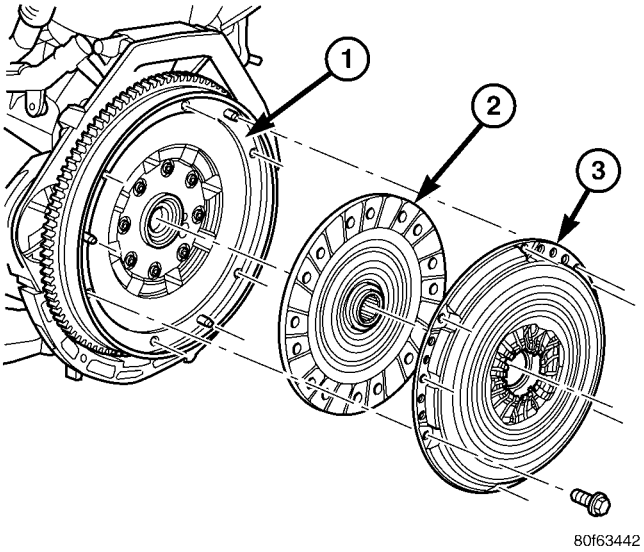

Fig. 12 Clutch Disc and Pressure Plate

1 - FLYWHEEL (DUAL-MASS)
2 - CLUTCH DISC
3 - PRESSURE PLATE

(4) Remove eight (8) flywheel-to-crankshaft bolts and remove flywheel assembly (Fig. 13).

INSTALLATION

INSTALLATION—1.6L

(1) Inspect clutch release bearing and lever for excessive wear and replace as necessary (Fig. 11).

(2) Clean the surfaces of the flywheel and pressure plate to make certain that all oil, grease, and rust have been removed.

(3) Verify the crankshaft mounting flange is free of debris, oil, grease, etc. Position the flywheel onto the engine crankshaft (Fig. 10).

(4) Install and torque the flywheel-to-crankshaft bolts to 95 N·m (70 ft.lbs.).

(5) Apply a very light coating of grease to the splines in the clutch disc hub.

(6) Position the clutch disc to the flywheel. Make sure the side marked “FLYWHEEL SIDE” faces the flywheel.

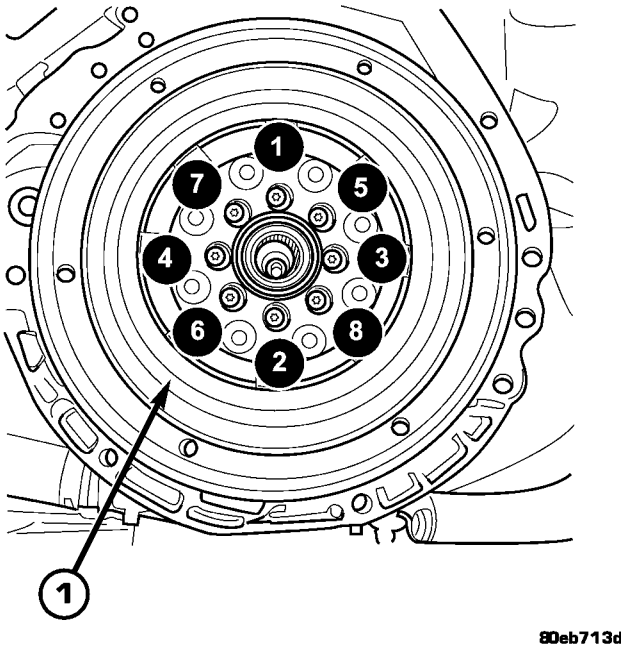

Fig. 13 Flywheel-to-Crankshaft Bolt Pattern

1 - FLYWHEEL ASSEMBLY

(7) Install the clutch pressure plate to the flywheel and clutch disc (Fig. 9). Finger tighten the six (6) pressure plate-to-flywheel bolts.

(8) Use Clutch Alignment Tool 6724 to position the clutch disc to the center of the flywheel (Fig. 14).

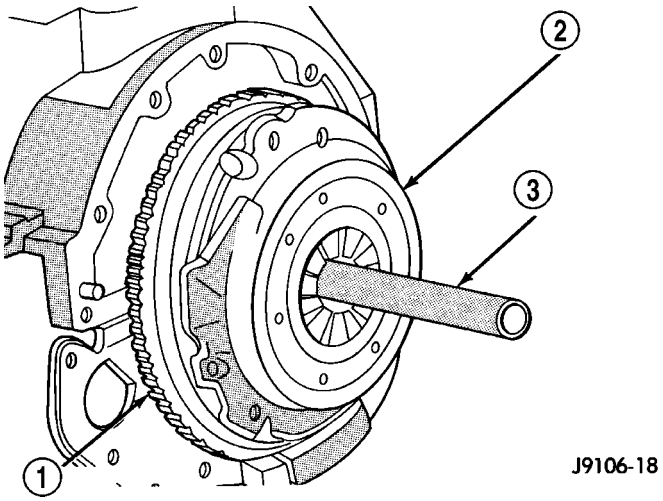

Fig. 14 Aligning Clutch Disc—Typical

1 - FLYWHEEL
2 - PRESSURE PLATE
3 - CLUTCH DISC ALIGNMENT TOOL

(9) Tighten pressure plate bolts evenly and in rotation a few threads at a time **The bolts must be tightened evenly and to specified torque to avoid distorting the pressure plate.**.

CLUTCH DISC AND PRESSURE PLATE (Continued)

(10) Using a “criss-cross” pattern, torque the pressure plate-to-flywheel bolts to 28 N·m (250 in.lbs.). Remove the clutch disc alignment tool.

(11) Apply light coat of Mopar® High Temperature Bearing Grease or equivalent to clutch disc hub and splines of transmission input shaft.

CAUTION: Do not over lubricate shaft splines. This will result in grease contamination of disc.

(12) Install transaxle. (Refer to 21 - TRANSMISSION/TRANSAXLE/MANUAL - INSTALLATION)

INSTALLATION—2.2L TD

(1) Inspect clutch release bearing and lever for excessive wear and replace as necessary. The release bearing is integral to the Concentric Slave Cylinder (CSC).

(2) Clean the surfaces of the flywheel and pressure plate to make certain that all oil, grease, and rust have been removed.

(3) Verify the crankshaft mounting flange is free of debris, oil, grease, etc. Position the flywheel onto the engine crankshaft (Fig. 13).

(4) Install flywheel to crankshaft. Install eight (8) flywheel-to-crankshaft bolts and torque to 45 N·m (33 ft. lbs.) plus an additional ¼ turn (90°) (Fig. 13).

(5) Apply a very light coating of grease to the splines in the clutch disc hub.

(6) Position the clutch disc to the flywheel. Make sure the side marked “FLYWHEEL SIDE” faces the flywheel (Fig. 12)..

(7) Install the clutch pressure plate to the flywheel and clutch disc (Fig. 12). Finger tighten the six (6) pressure plate-to-flywheel bolts.

(8) Use Clutch Alignment Tool 6724 to position the clutch disc to the center of the flywheel (Fig. 15).

(9) Tighten pressure plate bolts evenly and in rotation a few threads at a time **The bolts must be tightened evenly and to specified torque to avoid distorting the pressure plate.**.

(10) Using a “criss-cross” pattern, torque pressure plate bolts to 31 N·m (23 ft. lbs.). Remove the clutch disc alignment tool.

(11) Apply light coat of Mopar® High Temperature Bearing Grease or equivalent to clutch disc hub and splines of transmission input shaft.

CAUTION: Do not over lubricate shaft splines. This will result in grease contamination of disc.

(12) Install transaxle. (Refer to 21 - TRANSMISSION/TRANSAXLE/MANUAL - INSTALLATION)

2 - PRESSURE PLATE
3 - CLUTCH DISC ALIGNMENT TOOL

CLUTCH INTERLOCK/UPSTOP SWITCH

DESCRIPTION

The clutch interlock/upstop switch is an assembly consisting of two switches: an engine starter inhibit switch (interlock) and a clutch pedal upstop switch (Fig. 16). The switch assembly is located in the clutch/brake pedal bracket assembly (Fig. 17), each switch being fastened by four plastic wing tabs.

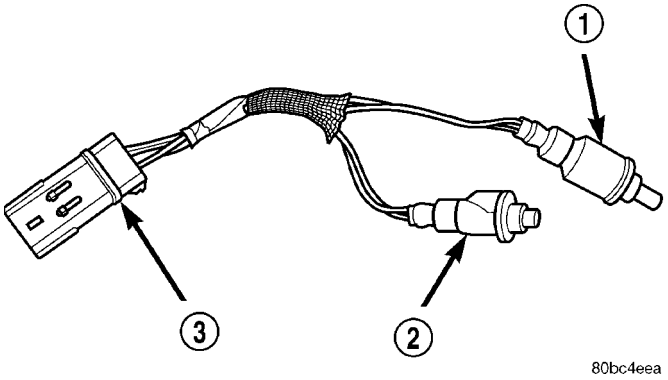

Fig. 16 Clutch Interlock/Upstop Switch

1 - UPSTOP SWITCH (IF EQUIPPED)
2 - INTERLOCK SWITCH
3 - CONNECTOR

CLUTCH INTERLOCK/UPSTOP SWITCH (Continued)

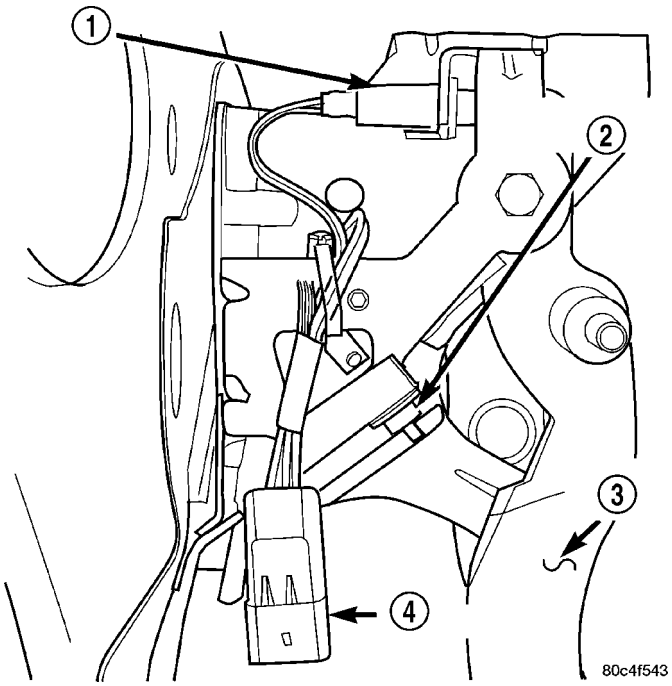

Fig. 17 Clutch/Brake Pedal Bracket

1 - UPSTOP SWITCH (IF EQUIPPED)
2 - INTERLOCK SWITCH
3 - CLUTCH PEDAL
4 - CONNECTOR

OPERATION

CLUTCH INTERLOCK SWITCH

The clutch interlock switch prevents engine starter operation and inadvertent vehicle movement with the clutch pedal in the up position (not depressed), or under normal conditions with the clutch engaged and the transaxle in gear.

WARNING: WHEN THERE IS A LOSS OF CLUTCH SYSTEM HYDRAULIC FLUID, OR THE CLUTCH MASTER CYLINDER PUSHROD IS DISCONNECTED FROM THE PEDAL LEVER, THE ENGINE MAY START WITH THE CLUTCH ENGAGED, CAUSING UNDESIRABLE VEHICLE MOVEMENT IF THE TRANSAXLE IS IN ANY GEAR.

The switch is open while the clutch pedal is at rest (up position). When the clutch pedal is fully depressed, the pedal lever (LHD), or the master cylinder push rod (RHD), closes the switch, completing the signal circuit from the PCM and closing the ground path, allowing engine starter operation. The interlock switch is not adjustable.

CLUTCH PEDAL UPSTOP SWITCH

NOTE: 2.4L-equipped models do not use the clutch pedal upstop switch/feature. These vehicles only utilize the starter inhibit (interlock) feature.

1.6L and 2.2L Turbo Diesel models: With the clutch pedal at rest, the clutch pedal upstop switch is closed, allowing speed control operation. When the clutch pedal is depressed, the upstop switch opens and signals the PCM to cancel speed control operation, and enter a modified engine calibration schedule to improve driveability during gear-to-gear shifts. The upstop switch is not adjustable.

DIAGNOSIS AND TESTING—CLUTCH INTERLOCK/UPSTOP SWITCH

LHD

NOTE: 2.4L-equipped models do not use the clutch pedal upstop switch/feature. These vehicles will only utilize the starter inhibit (interlock) feature.

The clutch interlock/upstop switch is an assembly consisting of two switches: an engine starter inhibit switch (interlock) and a clutch pedal upstop switch (Fig. 18). The switch assembly is located in the clutch/brake pedal bracket assembly (Fig. 19), each switch being fastened by four plastic wing tabs. The connector is secured to the pedal/bracket assembly by a plastic retainer.

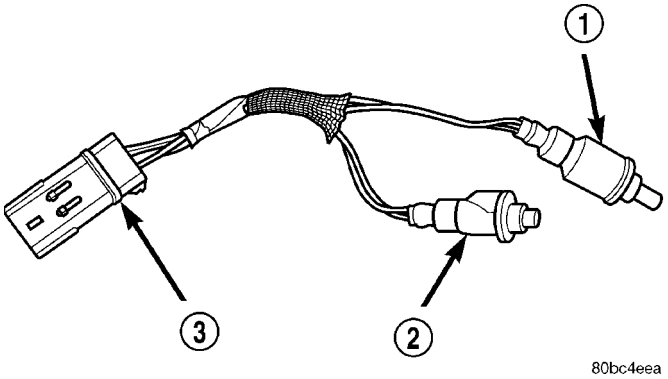

Fig. 18 Clutch Interlock/Upstop Switch

1 - UPSTOP SWITCH (IF EQUIPPED)
2 - INTERLOCK SWITCH
3 - CONNECTOR

RHD

The RHD clutch interlock/upstop switch (Fig. 20) consists of a single, multi-function switch that is activated by the hydraulic clutch master cylinder push rod.

3 - CONNECTOR

CLUTCH INTERLOCK SWITCH

Mechanical Test

(1) With the park brake set and the transaxle **IN NEUTRAL,** turn the ignition key to the start position. The engine starter should not crank with the clutch pedal at rest (not depressed). If the starter cranks, proceed to the electrical test to determine whether the switch is defective or the circuit is shorted. If the vehicle does not crank, proceed to the next step.

(2) With the park brake set and the transaxle **IN NEUTRAL,** fully depress the clutch pedal and turn the ignition key to the start position. The engine starter should crank. If the starter does not crank, visually inspect the clutch pedal for obstructions (floor mat, etc.) and for proper installation of the master cylinder push rod/bushing on the pedal pin. Also make sure the clutch pedal lever contacts and fully closes the switch for LHD applications.

Electrical Test

(1) Move ignition key to the “OFF/LOCK” position and remove key.

(2) Set park brake.

(3) Disconnect the clutch interlock/upstop switch connector.

(4) Using an ohmmeter, check for continuity between terminals 2 & 3 (Fig. 21) with the interlock switch not depressed (clutch pedal at rest). There should be no continuity between the terminals (open circuit).

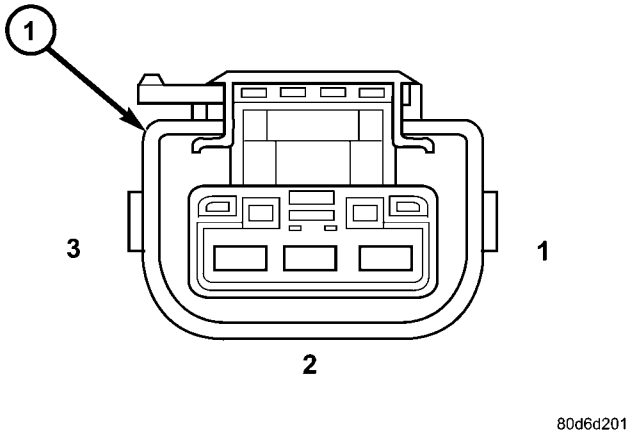

Fig. 21 Interlock/Upstop Switch Connector

1 - INTERLOCK/UPSTOP SWITCH CONNECTOR

(5) Fully depress the clutch pedal to close the switch. The switch button should compress at least 1.25 mm (0.050 in.) for LHD applications. The ohmmeter should show continuity (0 ohms).

CLUTCH INTERLOCK/UPSTOP SWITCH (Continued)

(6) For RHD applications, disconnect the push rod from the pedal pin and actuate the push rod by hand to close the switch. The ohmmeter should show continuity (0 ohms).

(7) If ohmmeter readings do not fall within these ranges, the switch assembly, or the pedal bracket assembly, is defective and should be replaced. If the switch tests ok, wiring is defective.

UPSTOP SWITCH

NOTE: 2.4L-equipped models do not use the clutch pedal upstop switch/feature. These vehicles will only utilize the starter inhibit (interlock) feature. PCM software will not recognize the upstop switch on 2.4L vehicles that have the switch, so upstop switch testing is not required. Proceed to Speed Control Diagnosis & Testing. (Refer to 8 - ELECTRICAL/SPEED CONTROL - DIAGNOSIS AND TESTING)

Mechanical Test (1.6L and 2.2L Turbo Diesel Models)

(1) Raise vehicle on hoist.

(2) Start engine and operate speed control to maintain speed.

(3) Depress clutch pedal at least 33 mm (1.30 in.). Speed control operation should terminate. If speed control does not terminate, the upstop switch is defective or the related wiring is shorted. Proceed to the upstop switch electrical test.

Electrical Test (1.6L and 2.2L Turbo Diesel Models)

(1) Move ignition key to the “OFF/LOCK” position and remove key.

(2) Set park brake.

(3) Disconnect the clutch interlock/upstop switch connector.

(4) Using an ohmmeter, check for continuity between terminals 1 & 2 (Fig. 21) with the upstop switch depressed (clutch pedal at rest). The ohmmeter should show continuity (0 ohms).

(5) Depress the clutch pedal at least 33 mm (1.30 in.) check for continuity between terminals 1 & 2. There should be no continuity between the terminals (open circuit).

(6) If ohmmeter readings do not fall within these ranges, the switch assembly is defective and should be replaced. If the switch tests ok, wiring is defective. Refer to Group 8W, Wiring Diagrams and repair defective wiring.

SERVICE DIAGNOSIS - CLUTCH INTERLOCK/UPSTOP SWITCH

CONDITION	POSSIBLE CAUSES	CORRECTION
ENGINE STARTER WON’T CRANK WHEN CLUTCH PEDAL IS PRESSED TO THE FLOOR	LHD - Clutch interlock switch does not have continuity when plunger is depressed 1.25 mm (1.30 in.).	Defective switch or open wiring circuit. Replace switch if necessary.
	RHD - Clutch interlock switch does not have continuity when plunger is fully depressed when removed from the pedal pin.	Defective pedal bracket assembly.
	Interlock switch plunger is not depressed when clutch pedal is pushed to the floor	Floor mat interferes with clutch pedal movement, clutch pedal bracket is bent, or the push rod/bushing is not properly installed.
	Problem is related to other components in the starting circuit.	Check other components in the starting circuit. Refer to Battery/Starting/Charging System in Group 8.
SPEED CONTROL DOES NOT TERMINATE WHEN CLUTCH PEDAL IS DEPRESSED	1.6L/2.2L TD Models: Upstop switch circuit is closed when clutch pedal is depressed, or harness is shorted.	Refer to Upstop Switch Electrical Test in this group. Repair wiring or replace switch assembly as necessary.
	2.0/2.4L Models: Speed control system failure.	Refer to Group 8P, Speed Control for further diagnosis and testing procedures.

CLUTCH INTERLOCK/UPSTOP SWITCH (Continued)

REMOVAL

REMOVAL - LHD

NOTE: Depending on vehicle build date, some vehicles will not have the clutch pedal upstop switch included in the switch assembly. These vehicles will only utilize the starter inhibit (interlock) feature.

(1) Disconnect and isolate battery negative cable.

(2) Remove left lower instrument panel bezel (Fig. 22).

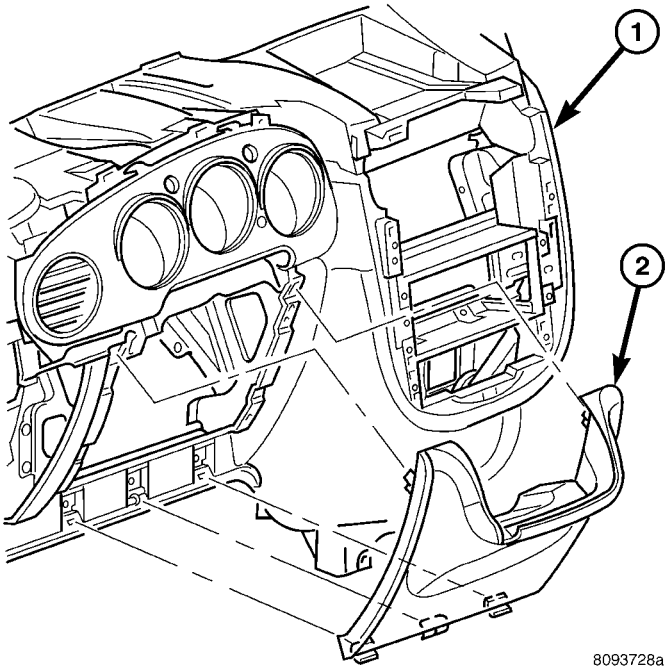

Fig. 22 Left Lower Instrument Panel Bezel

1 - INSTRUMENT PANEL
2 - INSTRUMENT PANEL STEERING COLUMN COVER

(3) Disconnect interlock switch and brake lamp switch connectors.

(4) Disconnect clutch master cylinder rod from clutch pedal pin. **Inspect plastic retainer upon removal. If retainer is damaged, it MUST be replaced.**

(5) Remove brake booster push rod retaining clip from brake pedal. Disengage rod from pedal (Fig. 23).

(6) Remove two pedal assembly bracket to instrument panel nuts (Fig. 24).

(7) Remove four brake booster/pedal bracket-to-dash panel nuts (Fig. 24).

(8) From under the hood, pull brake master cylinder/booster far enough forward to obtain pedal to bracket stud clearance.

(9) Remove the pedal bracket assembly (Fig. 24).

(10) Remove pedal pivot shaft and remove brake and clutch pedals.

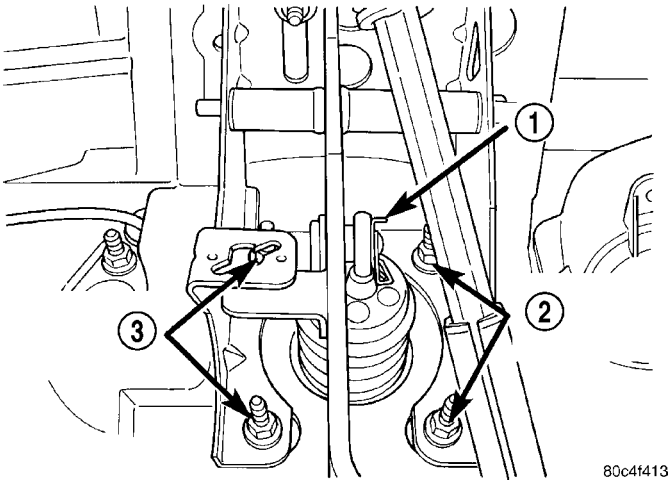

Fig. 23 Brake Booster Mounting Nuts and Rod Retaining Clip

1 - CLIP
2 - BOOSTER MOUNTING NUTS
3 - BOOSTER MOUNTING NUTS

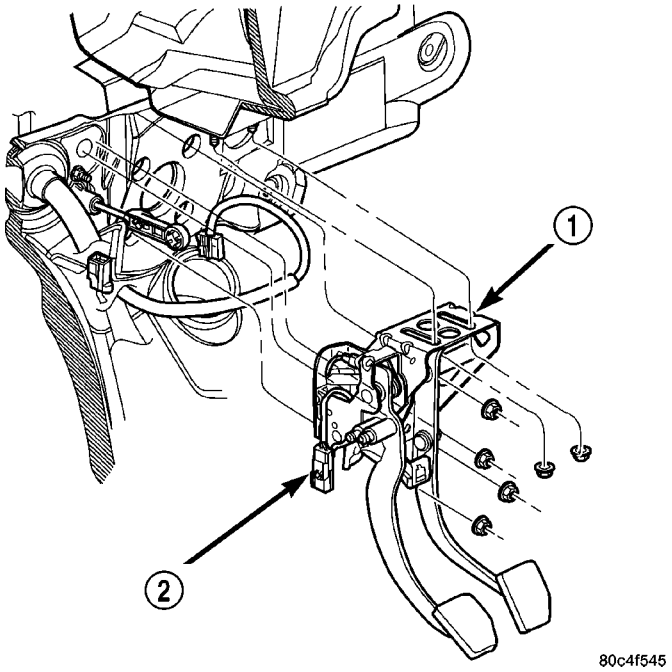

Fig. 24 Brake/Clutch Pedal Assembly Removal/ Installation

1 - CLUTCH/BRAKE PEDAL ASSEMBLY
2 - INTERLOCK/UPSTOP SWITCH CONNECTOR

CLUTCH INTERLOCK/UPSTOP SWITCH (Continued)

(11) Remove the interlock/upstop switch assembly (Fig. 25) from the brake/clutch pedal bracket assembly by depressing the four plastic wing tabs on each switch.

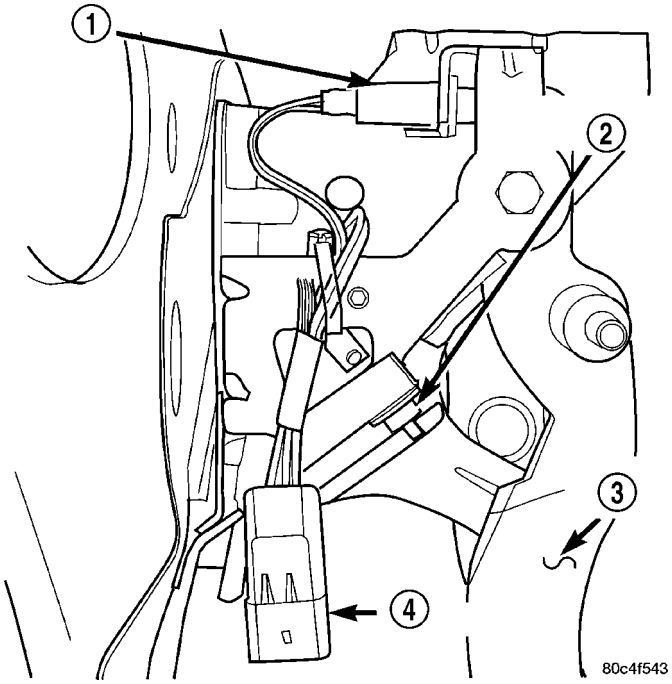

Fig. 25 Interlock/Upstop Switch

1 - UPSTOP SWITCH (IF EQUIPPED)
2 - INTERLOCK SWITCH
3 - CLUTCH PEDAL
4 - CONNECTOR

REMOVAL - RHD

(1) Remove lower instrument panel bezel (Fig. 26).

(2) Disconnect the master cylinder push rod from the pedal pin (Fig. 27). **Inspect push rod retainer for damage. If it is damaged (broken/cracked), it must be replaced.**

(3) Squeeze together the tangs on the switch cover plate and slide the plate off the switch housing.

(4) Disconnect the clutch interlock/upstop switch connector from the instrument panel wiring harness.

(5) Remove the switch from the vehicle.

INSTALLATION

INSTALLATION - LHD

NOTE: Proper switch harness routing is critical to switch durability. Note the harness routing and location of fasteners intended to keep wires from contacting pedals.

(1) Install switches into the pedal bracket assembly as shown in (Fig. 25). Route harness as was prior to removal.

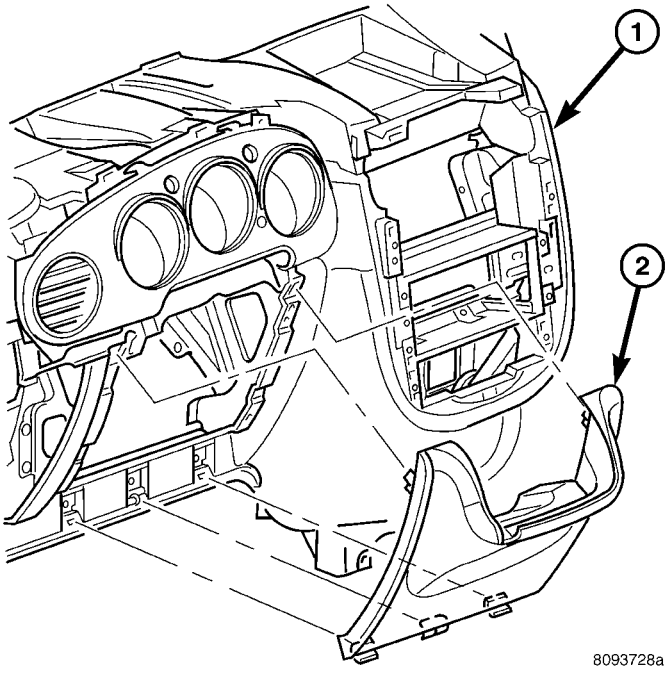

Fig. 26 Lower Instrument Panel Bezel—Typical

1 - INSTRUMENT PANEL
2 - INSTRUMENT PANEL STEERING COLUMN COVER

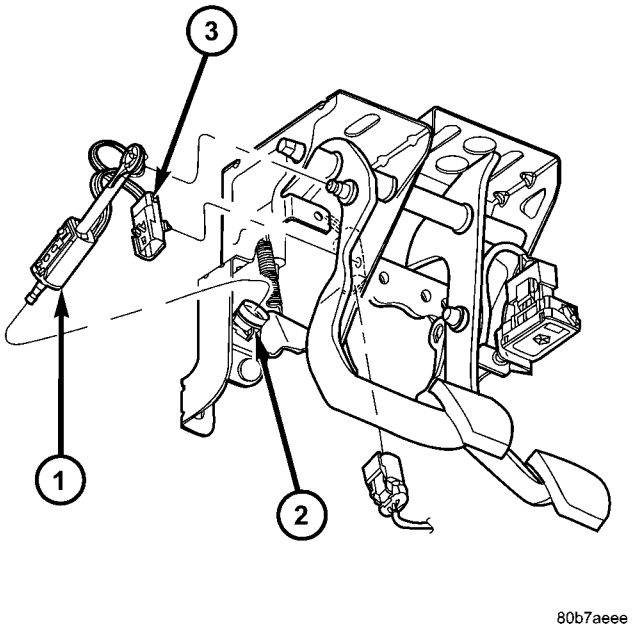

Fig. 27 Clutch Interlock/Upstop Switch

1 - INTERLOCK/UPSTOP SWITCH
2 - MASTER CYLINDER
3 - CONNECTOR

(2) Install clutch and brake pedals to pedal bracket, and install pivot shaft and nut. Torque pivot shaft nut to 42 N·m (31 ft. lbs.).

CLUTCH INTERLOCK/UPSTOP SWITCH (Continued)

(3) Install brake/clutch pedal bracket assembly into position. Install and tighten brake booster mounting nuts to 34 N·m (300 in. lbs.). Install and tighten pedal bracket-to-instrument panel nuts to 34 N·m (300 in. lbs.).

(4) Install new stop lamp switch. Refer to Stop Lamp Switch Removal and Installation.

(5) Connect brake booster rod to brake pedal. Install retainer clip (Fig. 23).

(6) Loosen adjustment screw on clutch master cylinder pushrod (Fig. 28). **Gently** lift clutch pedal upwards. **Raising pedal with excessive force can damage to the pedal upstop, causing excessive pedal travel.**

NOTE: Inspect plastic retainer upon removal. If retainer is damaged in any way (broken/cracked), it MUST be replaced.

(7) Connect clutch master cylinder pushrod to pedal pin and torque adjustment screw to 6 N·m (55 in. lbs.).

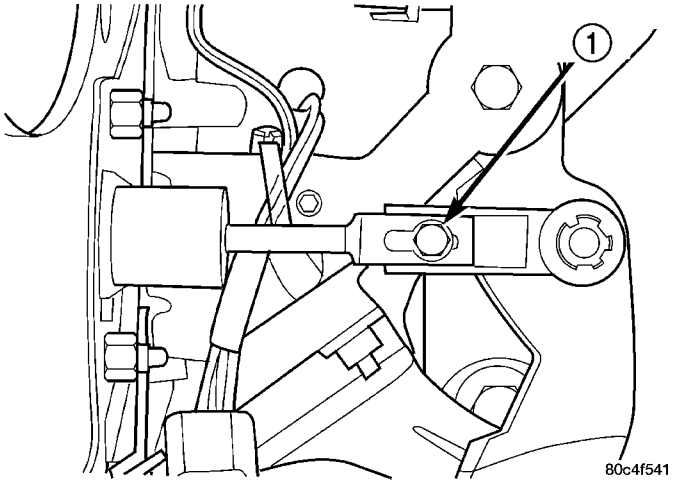

Fig. 28 Clutch Master Cylinder Pushrod Adjustment Screw

1 - ADJUSTMENT SCREW

(8) Connect interlock/upstop and stop lamp switch connectors.

(9) Install left lower instrument panel bezel (Fig. 22).

(10) Connect battery negative cable.

(11) Verify proper switch operation.

INSTALLATION - RHD

NOTE: Proper switch harness routing is critical to switch durability. Note the harness routing and location of fasteners intended to keep wires from contacting pedals.

(1) Install the clutch interlock/upstop switch onto the master cylinder push rod, making sure that the push rod is oriented with the push rod retainer toward the wiring of the switch. The master cylinder push rod must be snapped into the clutch interlock/upstop switch along the smaller diameter of the push rod between the snap ring and the transition to the larger diameter.

CAUTION: Improper assembly of the larger diameter of the push rod into the clutch interlock/upstop switch could cause damage to the switch or a clutch system failure.

(2) Install the switch cover plate.

CAUTION: Inspect the plastic push rod retainer for damage. If it is damaged (broken/cracked), it MUST be replaced.

(3) Connect clutch master cylinder pushrod to the clutch pedal pin.

(4) Route the wiring harness as it was prior to removal.

(5) Secure the switch connector retaining push pin into the appropriate hole in the pedal bracket assembly.

(6) Install lower instrument panel bezel (Fig. 26).

(7) Verify proper interlock/upstop switch operation.

CLUTCH RELEASE BEARING

DESCRIPTION

NOTE: Models equipped with the Diesel or Turbo Engine options utilize a release bearing which is integral to the Concentric Slave Cylinder (CSC). (Refer to 6 - CLUTCH/SLAVE CYLINDER - DESCRIPTION)

1.6/2.4L Models A conventional release bearing is used to engage and disengage the clutch pressure plate. The clutch release bearing is mounted on the transaxle front bearing retainer. The bearing is attached to and operated by the release lever (Fig. 29), which moves the bearing into contact with the clutch cover diaphragm spring.

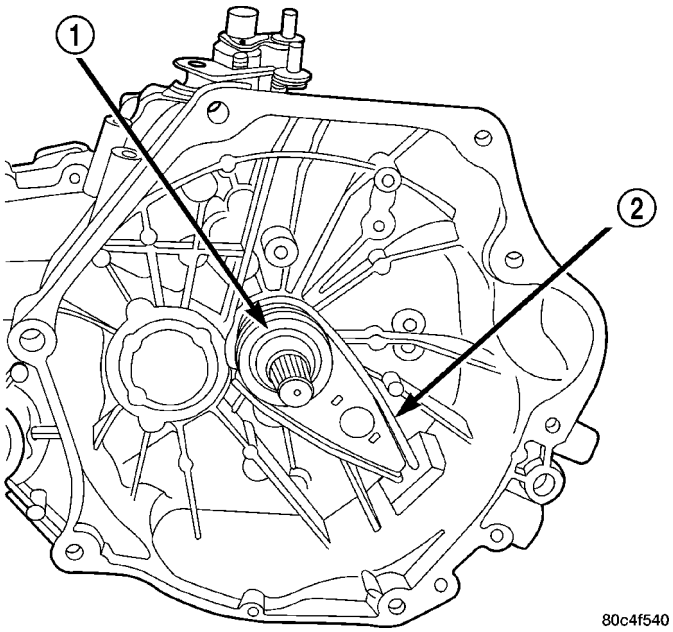

Fig. 29 Clutch Release Bearing and Lever (T350)

1 - RELEASE BEARING
2 - LEVER

OPERATION

The release bearing is operated by the release lever. Slave cylinder force causes the release lever to move the release bearing into contact with the diaphragm spring. As additional force is applied, the bearing presses the diaphragm spring fingers inward on the fulcrums. This action moves the pressure plate rearward, relieving clamping force on the clutch disc. Releasing pedal pressure removes clutch hydraulic pressure. The release bearing then moves away from the diaphragm spring which allows the pressure plate to exert clamping force on the clutch disc.

REMOVAL

NOTE: Models equipped with the Diesel and Turbo Engine option utilize a release bearing that is integral to the Concentric Slave Cylinder (CSC). (Refer to 6 - CLUTCH/SLAVE CYLINDER - REMOVAL)

(1) Remove the transaxle from the vehicle. (Refer to 21 - TRANSMISSION/TRANSAXLE/MANUAL - REMOVAL)

(2) Move the lever and bearing assembly (Fig. 30) to a vertical in-line position. Grasp the release lever with two hands in the pivot stud socket area. Pull with even pressure and the lever will pop off the pivot–stud. Do not use a screwdriver or pry bar to pop off the lever. This may damage the spring clip on the lever.

(3) As a unit, remove the lever from the bearing thrust plate. Be careful not to damage retention tabs on bearing.

(4) Examine the condition of the bearing. **It is pre-lubricated and sealed and should not be immersed in oil or solvent.**

(5) The bearing should turn smoothly when held in the hand under a light thrust load. A light drag caused by the lubricant fill is normal. If the bearing is noisy, rough, or dry, replace the complete bearing assembly with a new bearing.

(6) Check the condition of the pivot stud spring clips on back side of clutch release lever. If the clips are broken or distorted, replace the clutch release lever.

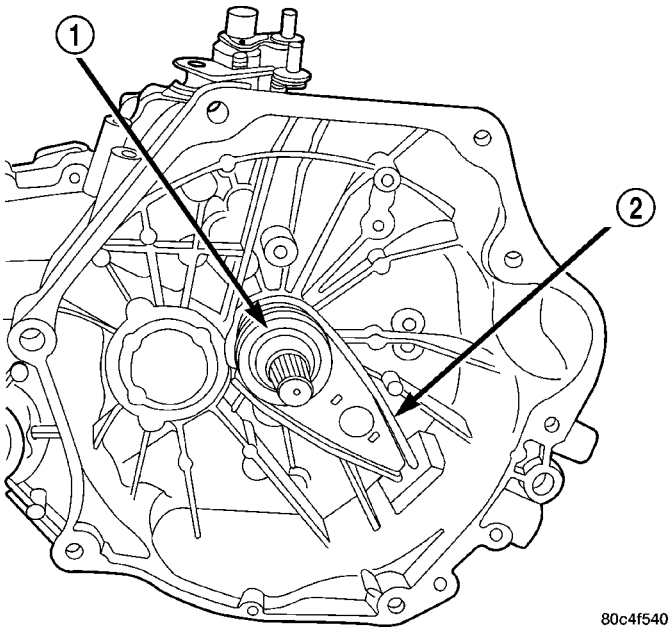

Fig. 30 Release Bearing and Lever

1 - RELEASE BEARING
2 - LEVER

CLUTCH RELEASE BEARING (Continued)

INSTALLATION

(1) The pivot ball pocket in the lever, as well as the lever arms should be lubricated with grease prior to installation.

(2) Assemble the lever to the bearing (Fig. 30). The small pegs on the bearing must go over the lever arms.

(3) Slide the bearing and lever assembly onto the input shaft bearing retainer, as a unit.

(4) Snap the clutch release lever onto the pivot ball.

(5) Reinstall transaxle assembly. (Refer to 21 - TRANSMISSION/TRANSAXLE/MANUAL - INSTALLATION)

FLYWHEEL

DESCRIPTION

1.6L Equipped Models

1.6L Equipped Models utilize a conventional flywheel assembly, which is a solid rotating mass fastened to the rear of the crankshaft (Fig. 31). The flywheel also incorporates an integral starter ring gear.

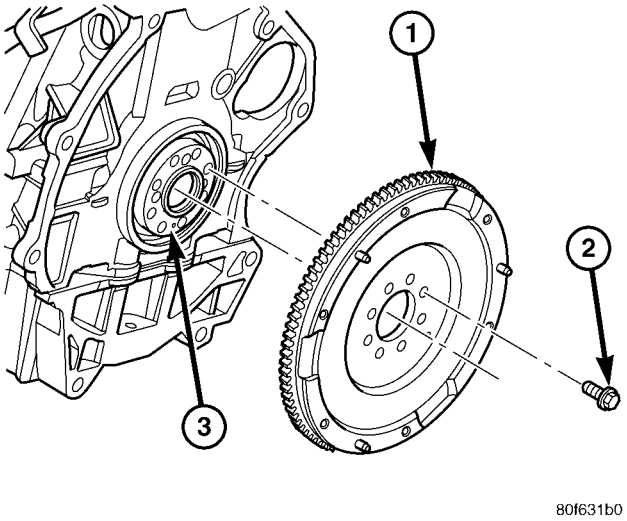

Fig. 31 Flywheel-to-Crankshaft

1 - FLYWHEEL
2 - BOLT (8)
3 - CRANKSHAFT FLANGE

2.2L Turbo Diesel Equipped Models

The Dual-Mass Flywheel (DMF) is utilized on 2.2L TD/5-speed models. Models equipped with the turbocharged 2.4L Engine option also utilize a Dual-Mass Flywheel, but it is a serviceable part of the Modular Clutch Assembly. (Refer to 6 - CLUTCH/MODULAR CLUTCH - DESCRIPTION). The DMF consists of two decoupled masses (primary and secondary mass) which are connected via a spring/damping system (Fig. 32). The primary flywheel side is bolted to the crankshaft. The secondary flywheel face serves as the driving member to the clutch disc. Internal springs between the flywheels are used to couple the masses while dampening energy. The flywheel also incorporates the ring gear around the outer circumference to mesh with the starter to permit engine cranking.

OPERATION

The flywheel serves to dampen the engine firing pulses. The heavy weight of the flywheel relative to the rotating mass of the engine components serves to stabilize the flow of power to the remainder of the drivetrain. The crankshaft has the tendency to attempt to speed up and slow down in response to the cylinder firing pulses. The flywheel dampens these impulses by absorbing energy when the crankshaft speeds and releasing the energy back into the system when the crankshaft slows down.

On a Dual Mass Flywheel, the additional secondary mass coupled to the transmission lowers the natural frequency of the transmission rotating elements. This decreases the transmission gear rattle. The damper springs between the two flywheel masses replace the clutch disc damper springs and assist in a smooth transfer of torque to the transmission.

CAUTION: The Dual Mass Flywheel is serviced as an assembly only and should never be disassembled.

FLYWHEEL (Continued)

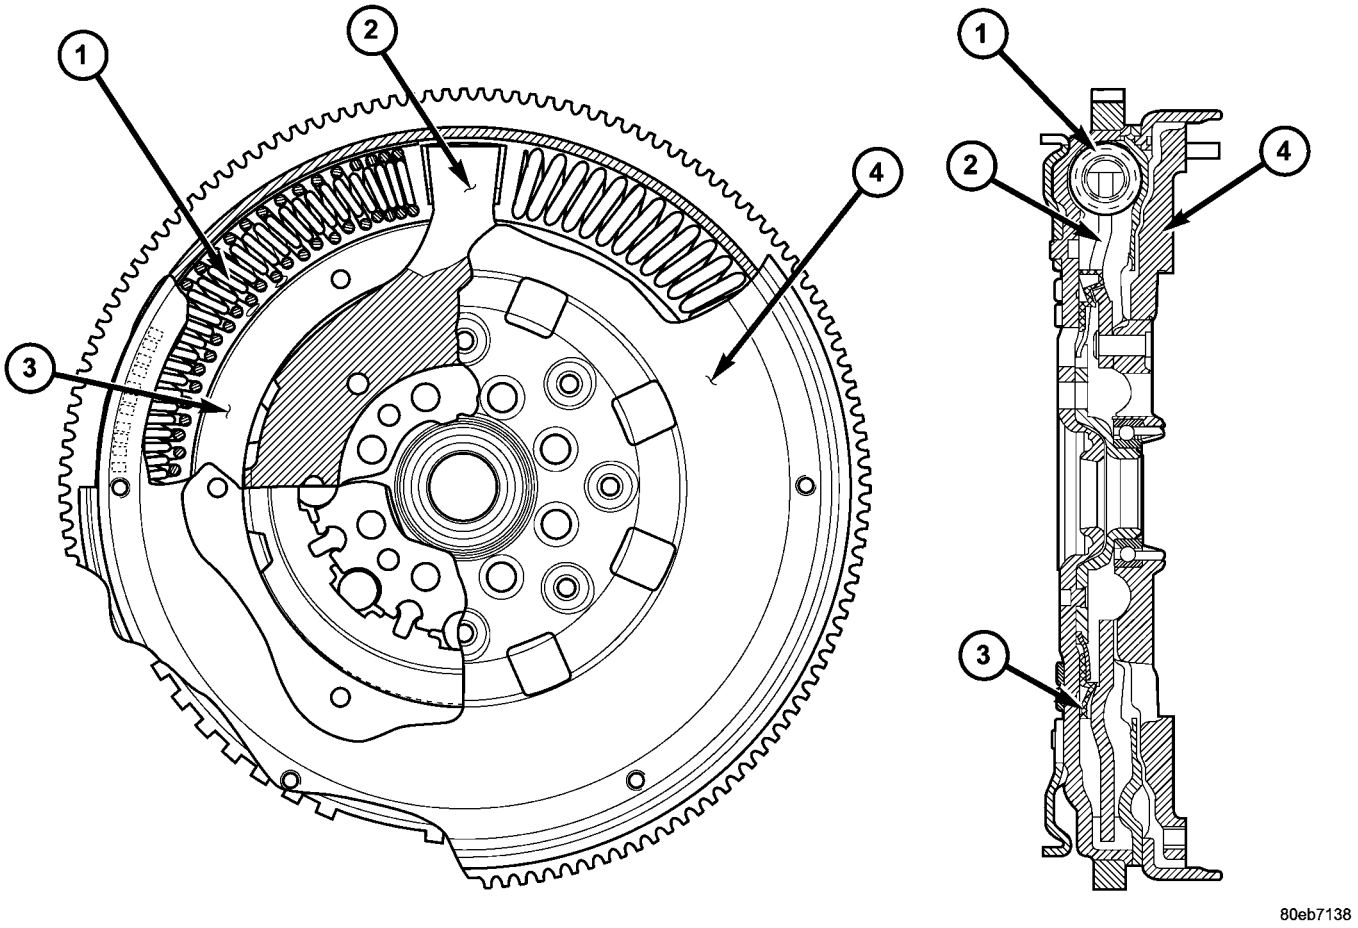

Fig. 32 Dual-Mass Flywheel (DMF)

1 - THRUST SPRING
2 - FLANGE/DIAPHRAGM SPRING

4 - SECONDARY MASS

FLYWHEEL (Continued)

REMOVAL

(1) Remove transaxle (Refer to 21 - TRANSMISSION/TRANSAXLE/MANUAL - REMOVAL).

(2) Remove clutch pressure plate and disc (Refer to 6 - CLUTCH/CLUTCH DISC - REMOVAL).

(3) Remove eight (8) flywheel-to-crankshaft bolts and remove flywheel assembly (Fig. 33) (Fig. 34).

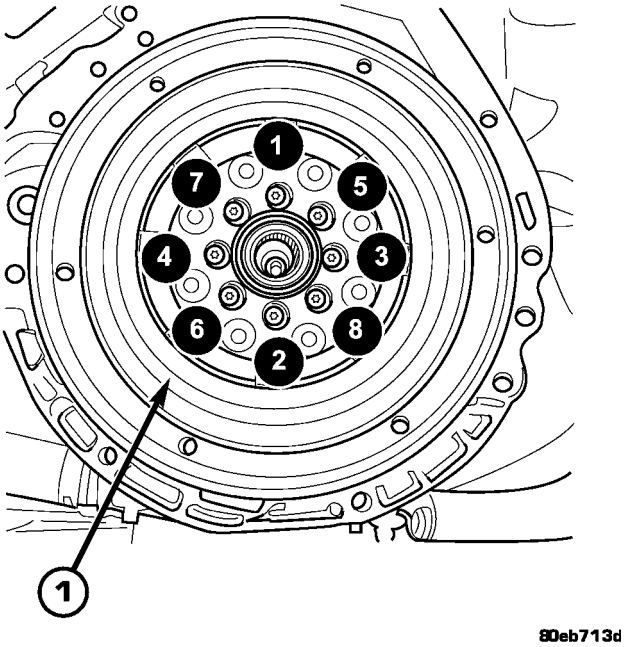

Fig. 33 Flywheel Bolt Pattern—2.2L Turbo Diesel Engine

1 - FLYWHEEL ASSEMBLY

INSTALLATION

(1) Clean the surfaces of the flywheel and pressure plate to make certain that all oil, grease, and rust have been removed.

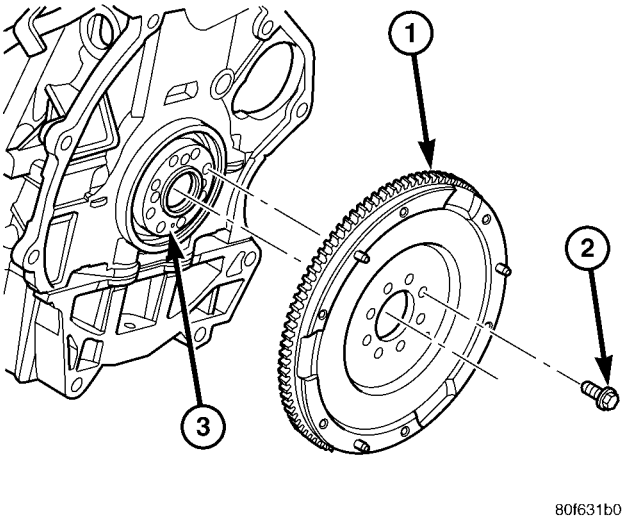

Fig. 34 Flywheel-to-Crankshaft—1.6L Engine

1 - FLYWHEEL
2 - BOLT (8)
3 - CRANKSHAFT FLANGE

(2) **2.2L Diesel Engine Equipped Models (Fig. 33):** Install flywheel to crankshaft. Install eight (8) flywheel-to-crankshaft bolts and torque to 45 N·m (33 ft. lbs.) plus an additional ¼ turn (90°).**1.6L Engine Equipped Models (Fig. 34):** Install and torque the flywheel-to-crankshaft bolts to 95 N·m (70 ft.lbs.).

(3) Install clutch pressure plate and disc (Refer to 6 - CLUTCH/CLUTCH DISC - INSTALLATION).

(4) Install transaxle assembly (Refer to 21 - TRANSMISSION/TRANSAXLE/MANUAL - INSTALLATION).

MASTER CYLINDER - LHD

DESCRIPTION

CAUTION: The clutch master cylinder pushrod adjustment must not be used to change pedal free-play or pedal height. Using the adjustable pushrod for these reasons will result in premature clutch wear or system over/undertravel.

NOTE: The clutch master cylinder/hydraulic release system does not have its own reservoir. This system is supplied fluid from the brake master cylinder reservoir.

The clutch master cylinder mounts to the dash panel (Fig. 35) and consists of a push rod (adjustable on LHD models), a piston and cylinder housing, an interconnecting hydraulic tube and a supply hose which connects to the brake master cylinder reservoir for fluid supply (Fig. 36).

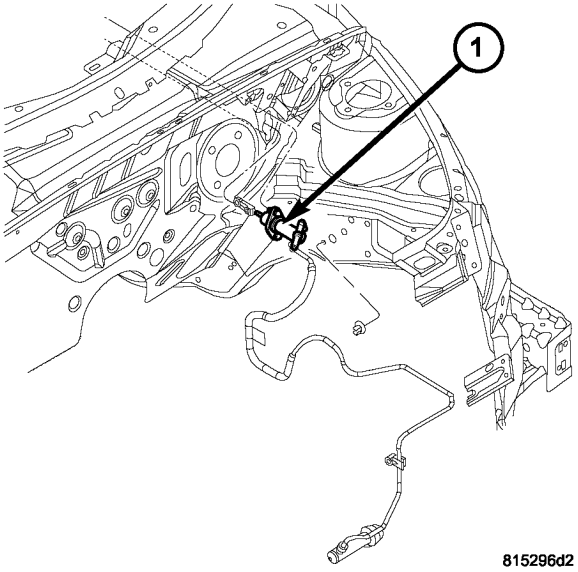

Fig. 35 Clutch Master Cylinder

1 - CLUTCH MASTER CYLINDER

OPERATION

The clutch master cylinder (Fig. 35) (Fig. 36) produces the hydraulic pressure necessary to disengage the clutch. When the clutch pedal is depressed, the push rod moves the piston to produce pressure in the cylinder. This pressure moves fluid through the system to the slave cylinder, which in turn operates the release lever and bearing, disengaging the clutch. When the clutch pedal is released, pressure is relieved and the return spring returns the piston to its original position until the next pedal actuation.

1 - AIR CLEANER ASSEMBLY

MASTER CYLINDER - LHD (Continued)

(2) Disconnect battery negative cable.
(3) Remove lower instrument panel bezel (Fig. 38).

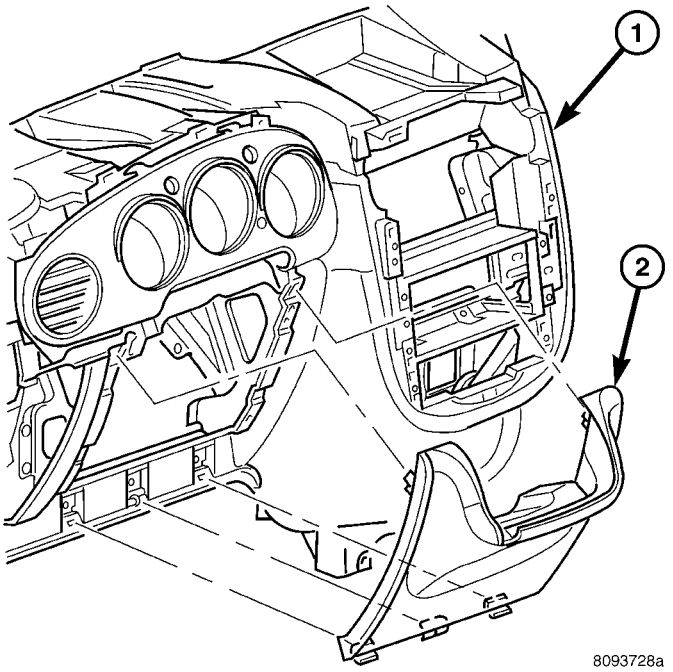

Fig. 38 Left Lower Instrument Panel Bezel

1 - INSTRUMENT PANEL
2 - INSTRUMENT PANEL STEERING COLUMN COVER

(4) Remove clip and disconnect the brake booster input rod from the brake pedal pin (Fig. 39).
(5) Remove the brake booster mounting nuts (Fig. 39).

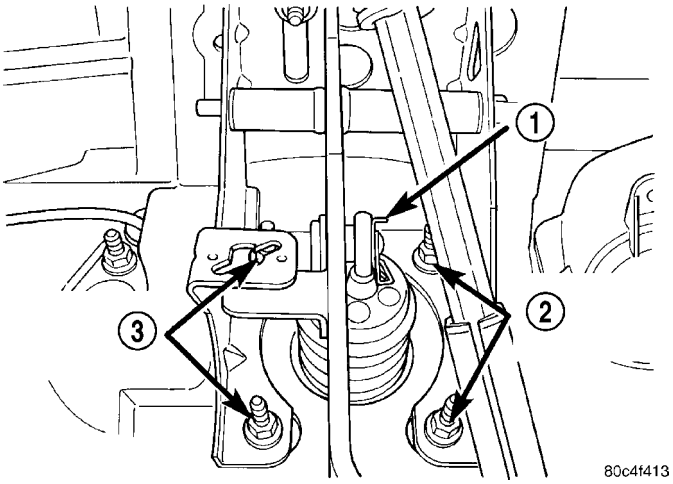

Fig. 39 Brake Booster Mounting Nuts

1 - CLIP
2 - BOOSTER MOUNTING NUTS
3 - BOOSTER MOUNTING NUTS

(6) Slide brake booster forward enough to gain access to and remove clutch master cylinder.
(7) Disconnect clutch master cylinder pushrod from clutch pedal. **Inspect retainer bushing and replace if damaged in any way.**
(8) Remove two clutch master cylinder retaining nuts (Fig. 40).

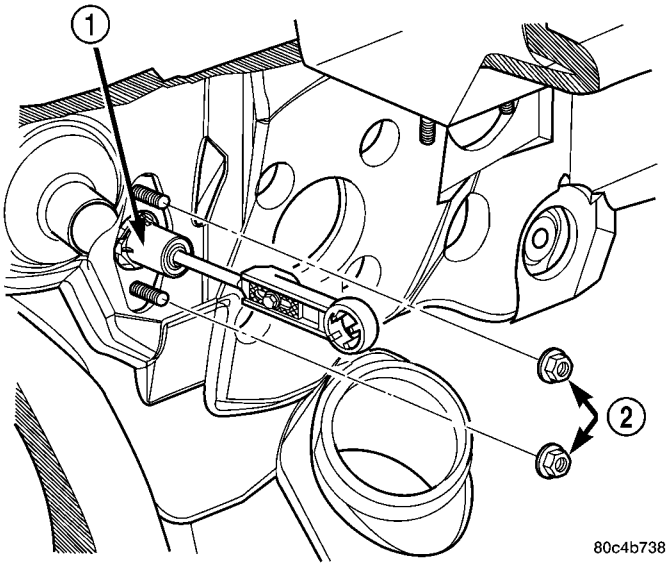

Fig. 40 Master Cylinder Mounting Nuts

1 - MASTER CYLINDER
2 - NUTS

MASTER CYLINDER - LHD (Continued)

(9) Remove PDC bracket and position out of way.

(10) Disconnect hydraulic supply tube at clutch slave cylinder. To completely drain clutch master cylinder and tubing, remove brake master cylinder cap.

(a) **1.6L/2.4L N/A Models:** Raise vehicle on hoist. Using suitable screwdriver, release both hydraulic tube retaining clips (Fig. 41). Disconnect tube and drain fluid into suitable container. Lower vehicle.

(b) **2.4L Turbo & Diesel Models:** Using suitable screwdriver, release both hydraulic tube retaining clips (Fig. 42). Disconnect tube and drain fluid into suitable container.

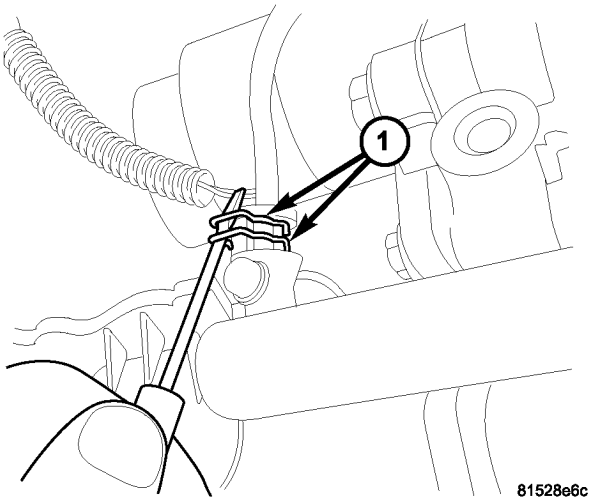

Fig. 41 Hydraulic Tube Retainer Clips - 1.6/2.4L

1 - RETAINER CLIPS

(11) Remove brake master cylinder cap to vent system for proper drainage. Disconnect clutch master cylinder supply line from brake master cylinder reservoir (Fig. 43). Cap off or collect fluid spillage from reservoir port.

CAUTION: Use care when removing clutch master cylinder from engine compartment. Aggressive handling can result in a damaged hydraulic tube and improper clutch release operation upon reassembly.

CAUTION: Brake fluid will damage painted surfaces. If brake fluid is spilled on any painted surfaces, wash it off immediately with water.

3 - CLUTCH MASTER CYLINDER SUPPLY HOSE

MASTER CYLINDER - LHD (Continued)

(4) Fill clutch hydraulic release system with fluid:

(a) **1.6L/2.4L N/A Models:** Fill brake master cylinder to the top with suitable DOT3 fluid. Leave cap off. Raise vehicle on hoist.

(b) Remove bleed port protective cap, and install suitable size and length of clear hose to monitor and divert fluid into suitable container.

(c) Release only the lower hydraulic tube snap ring, pull outward on tube until it stops against the second ring, opening up the bleed circuit and starting the air purge and fluid fill process (Fig. 48).

(d) Lower vehicle, but only enough to gain access to and fill the brake master cylinder.

(e) Top off brake master cylinder fluid level while air is purged and fluid drains from bleed port. Continue this until no air bubbles are seen and a solid column of fluid exists.

(f) Close hydraulic bleed circuit. Insert hydraulic pipe fully into slave cylinder and depress retaining ring. Remove drain hose.

(g) **2.4L Turbo & 2.2L Turbo Diesel** Fill brake master cylinder to the top with suitable DOT3 fluid. Leave cap off.

(h) Remove bleed port protective cap, and install suitable size and length of clear hose to divert fluid into suitable container.

(i) Release only the inboard hydraulic tube snap ring, pull outward on tube until it stops against the second ring, opening up the bleed circuit and starting the fluid fill process (Fig. 49).

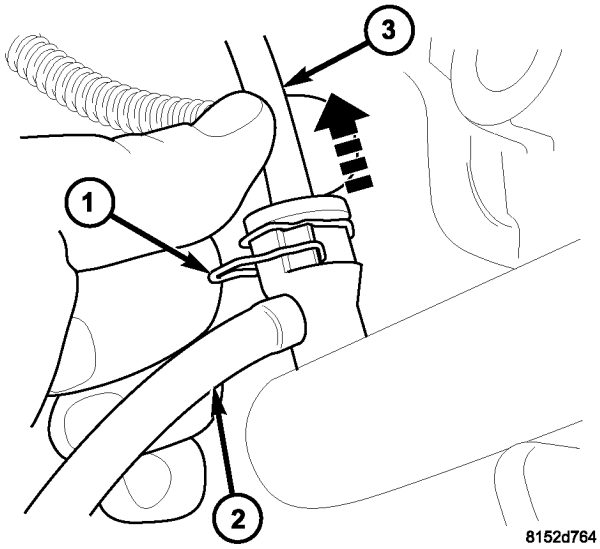

Fig. 48 Opening Hydraulic Circuit Bleed - 1.6/2.4L Models

1 - RETAINING RING
2 - CLEAR HOSE
3 - HYDRAULIC TUBE

(j) Top off brake master cylinder fluid level while air is purged and fluid drains from bleed port. Continue this until no air bubbles are seen and a solid column of fluid exists.

(k) Close hydraulic bleed circuit. Insert hydraulic pipe fully into slave cylinder and depress retaining ring. Remove drain hose.

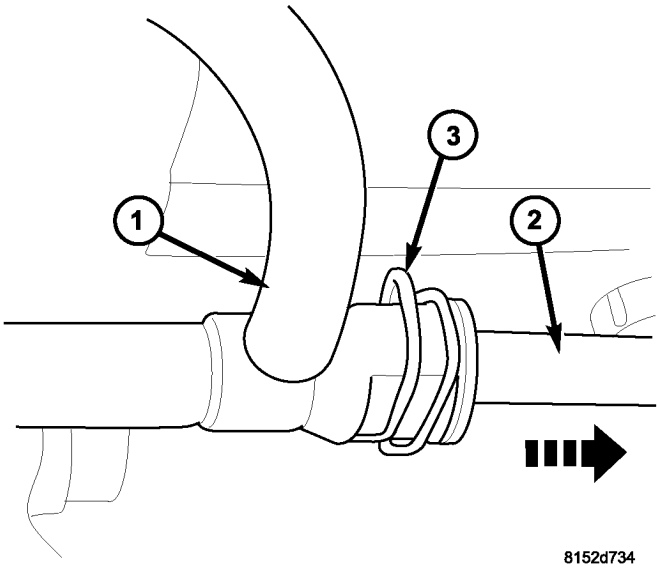

Fig. 49 Opening Hydraulic Circuit Bleed Port

1 - CLEAR HOSE
2 - HYDRAULIC TUBE
3 - RETAINER RING

CAUTION: Due to clutch master cylinder design and placement, the master cylinder body traps a significant amount of air which does not purge by means of normal methods. It is necessary to position master cylinder body vertical, with pushrod pointing down, for about ten seconds to purge air trapped from end of cylinder. Failure to perform this step upon assembly will result in inadequate system bleeding and poor release system functionality.

(5) Verify that brake master cylinder reservoir is full and cap is off.

(6) Position master cylinder body vertically, with pushrod pointing down, for about ten seconds to purge air trapped from end of cylinder.

MASTER CYLINDER - LHD (Continued)

(7) Install master cylinder body to dash panel. From inside vehicle, install and torque two clutch master cylinder-to-dash panel retaining nuts (Fig. 50) to 15 N·m (130 in. lbs.) torque.

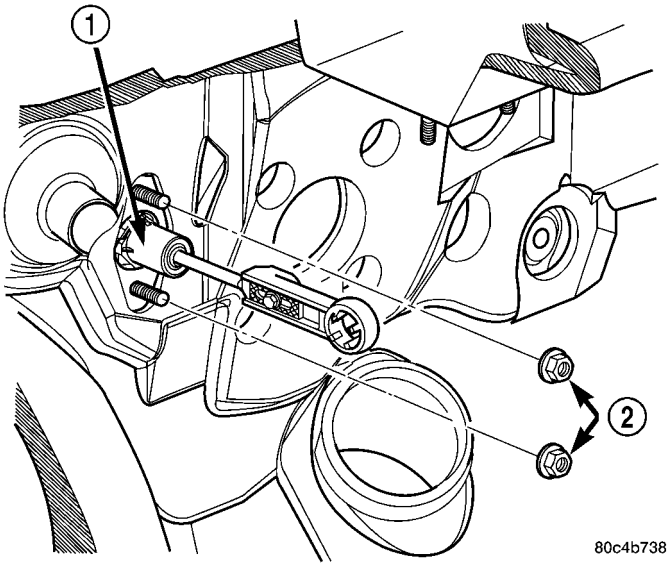

Fig. 50 Master Cylinder Mounting Nuts

1 - MASTER CYLINDER
2 - NUTS

(8) Loosen master cylinder pushrod adjustment screw (Fig. 51).

(9) Connect clutch master cylinder rod to clutch pedal pin. An audible “click” should be heard. If damaged, replace nylon retainer.

(10) Adjust clutch pedal position. Gently lift upward on clutch pedal. Tighten adjustment screw to 6 N·m (55 in. lbs.) torque.

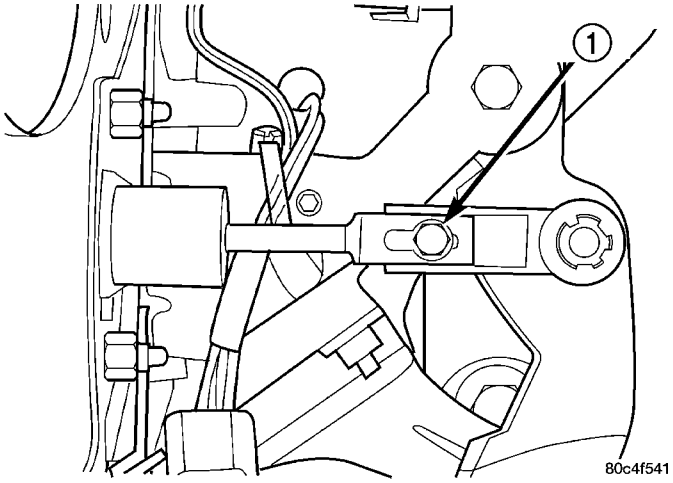

Fig. 51 Clutch Pedal Adjustment

1 - ADJUSTMENT SCREW

(11) Install brake booster into position. Connect push rod to brake pedal pin (Fig. 52).

(12) Install and torque brake booster-to-cowl panel nuts (Fig. 52) to 34 N·m (300 in.lbs.). Install push rod retaining clip.

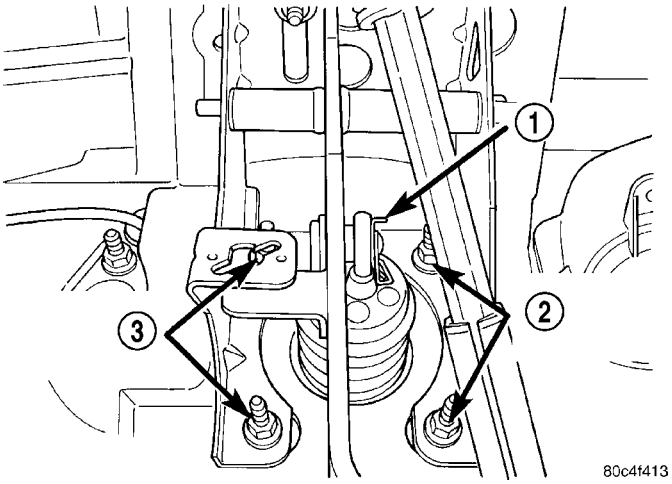

Fig. 52 Brake Booster Mounting Nuts

1 - CLIP
2 - BOOSTER MOUNTING NUTS
3 - BOOSTER MOUNTING NUTS

(13) Replace stop lamp switch. Refer to Stop Lamp Switch Removal and Installation.

(14) Install lower instrument panel bezel (Fig. 53).

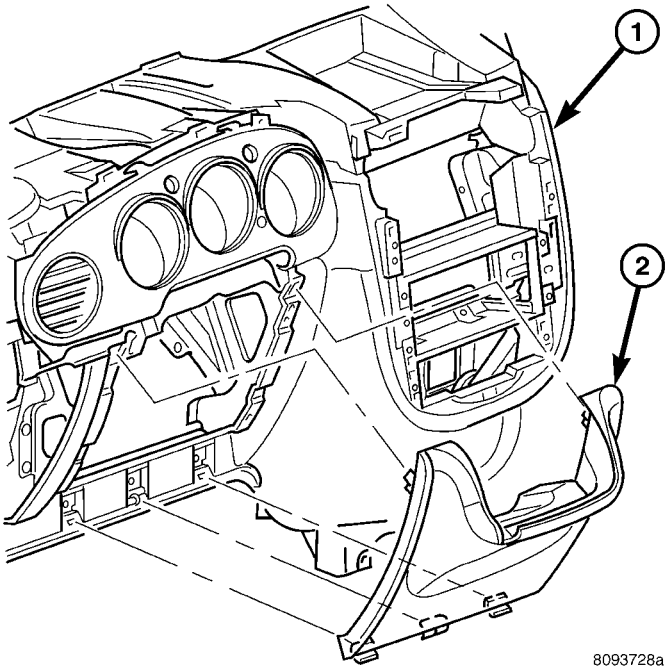

Fig. 53 Left Lower Instrument Panel Bezel

1 - INSTRUMENT PANEL
2 - INSTRUMENT PANEL STEERING COLUMN COVER

MASTER CYLINDER - LHD (Continued)

(15) Install PDC bracket into position.
(16) Raise vehicle on hoist.
(17) Connect battery negative cable.
(18) Install air cleaner assembly (Fig. 54).

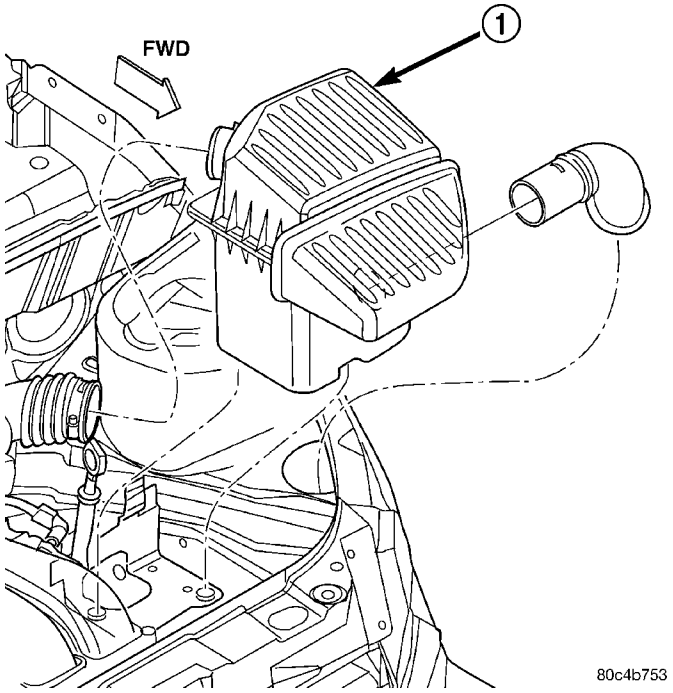

Fig. 54 Air Cleaner Assembly Removal/Installation—Typical

1 - AIR CLEANER ASSEMBLY

(19) Verify that brake master cylinder reservoir is full. Top off with DOT 3 brake fluid if necessary.

(20) Actuate clutch pedal a minimum of fifty times to allow any air ingested into the system to vent to the master cylinder reservoir. If residual air becomes trapped in the system, it is necessary to bleed the clutch hydraulic system. (Refer to 6 - CLUTCH - STANDARD PROCEDURE)

(21) Verify proper clutch release system operation.

MASTER CYLINDER - RHD

DESCRIPTION

The clutch master cylinder mounts to the dash panel (Fig. 55) and consists of a piston and cylinder housing, an actuating push rod, and an interconnecting hydraulic tube. Fluid is supplied to the clutch master cylinder via the brake master cylinder reservoir.

OPERATION

The clutch master cylinder (Fig. 55) produces the hydraulic pressure necessary to disengage the clutch. When the clutch pedal is depressed, the push rod moves the piston to produce pressure in the cylinder. This pressure moves fluid through the system to the

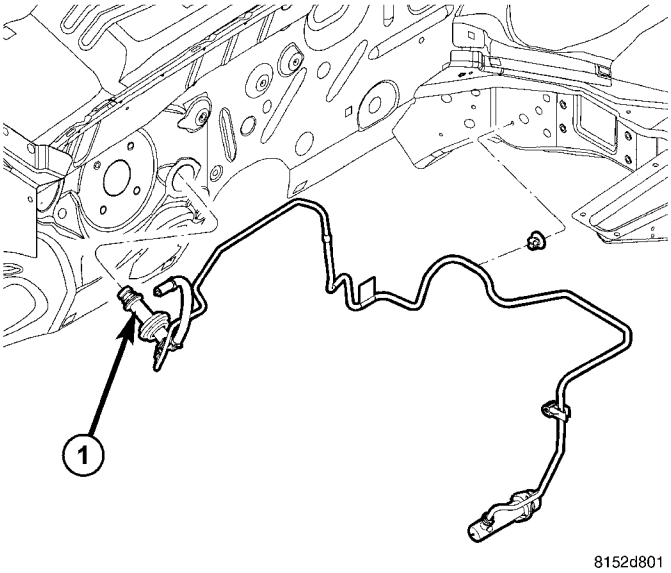

Fig. 55 Master Cylinder Mounting—RHD

1 - RESERVOIR

slave cylinder, which in turn operates the release lever and bearing (T350 Models Only), disengaging the clutch. When the clutch pedal is released, pressure is relieved and the return spring returns the piston to its original position until the next pedal actuation.

REMOVAL

(1) Remove air cleaner assembly (Fig. 56).

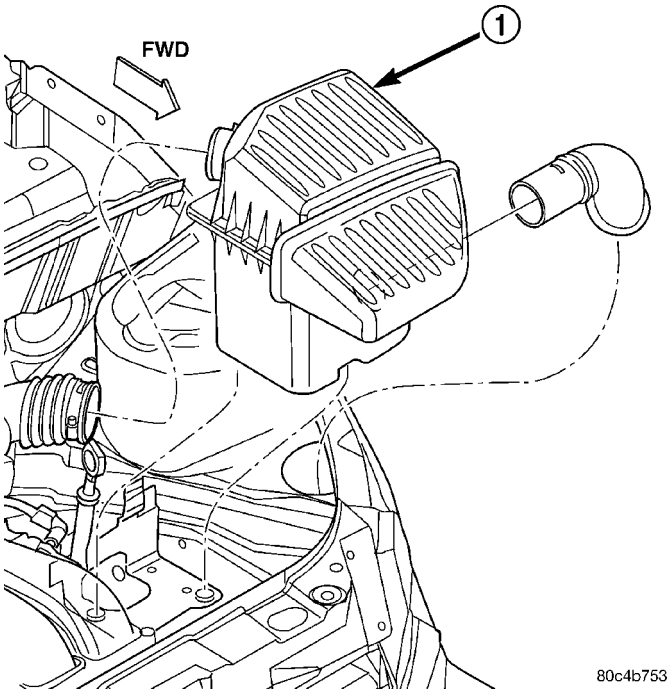

Fig. 56 Air Cleaner Assembly Removal/Installation

1 - AIR CLEANER ASSEMBLY

(2) Disconnect battery negative cable.

MASTER CYLINDER - RHD (Continued)

CAUTION: Brake fluid will damage painted surfaces. If brake fluid is spilled on any painted surfaces, wash it off immediately with water.

(3) Remove PDC bracket and position out of way.

(4) Disconnect hydraulic supply tube at clutch slave cylinder. To completely drain clutch master cylinder and tubing, remove brake master cylinder cap.

(a) **1.6L/2.4L N/A Models:** Raise vehicle on hoist. Using suitable screwdriver, release both hydraulic tube retaining clips (Fig. 57). Disconnect tube and drain fluid into suitable container. Lower vehicle.

(b) **2.4L Turbo & Diesel Models:** Using suitable screwdriver, release both hydraulic tube retaining clips (Fig. 58). Disconnect tube and drain fluid into suitable container.

(8) Install clutch master cylinder body through dash panel to pedal bracket assembly and rotate to secure (Fig. 73). **1.6/2.4L models: Rotate master cylinder clockwise (facing dash from underhood) to install. 2.2L Turbo-Diesel Models: Rotate master cylinder counter-clockwise (facing dash from underhood) to install.**

(9) Install and secure grommet (Fig. 73).

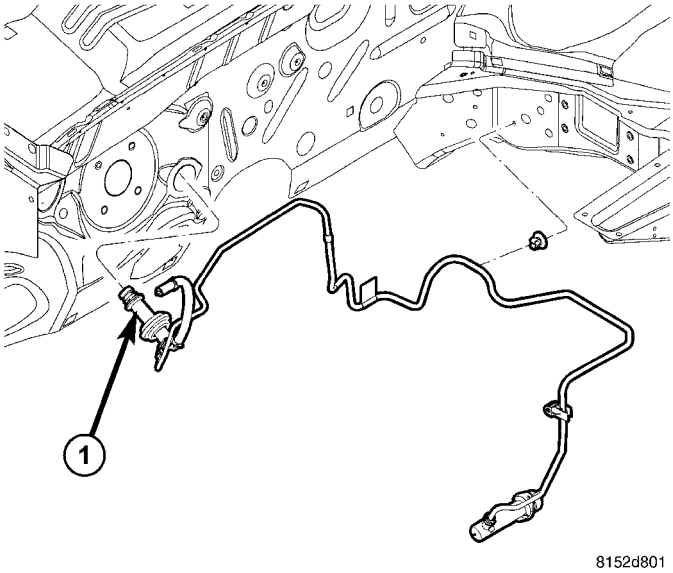

Fig. 73 Master Cylinder Mounting—RHD

1 - RESERVOIR

(10) From inside vehicle, connect clutch master cylinder rod to clutch pedal pin. An audible “click” should be heard. If damaged, replace nylon retainer.

(11) Install brake booster into position. Connect push rod to brake pedal pin (Fig. 74).

(12) Install and torque brake booster-to-dash panel nuts (Fig. 74) to 34 N·m (300 in.lbs.). Install push rod retaining clip.

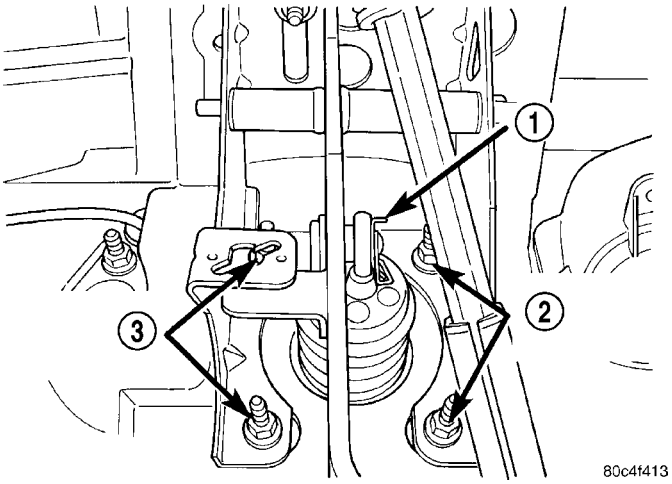

Fig. 74 Brake Booster Mounting Nuts

1 - CLIP
2 - BOOSTER MOUNTING NUTS
3 - BOOSTER MOUNTING NUTS

(13) Replace stop lamp switch. Refer to Stop Lamp Switch Removal and Installation.

(14) Install lower instrument panel bezel (Fig. 75).

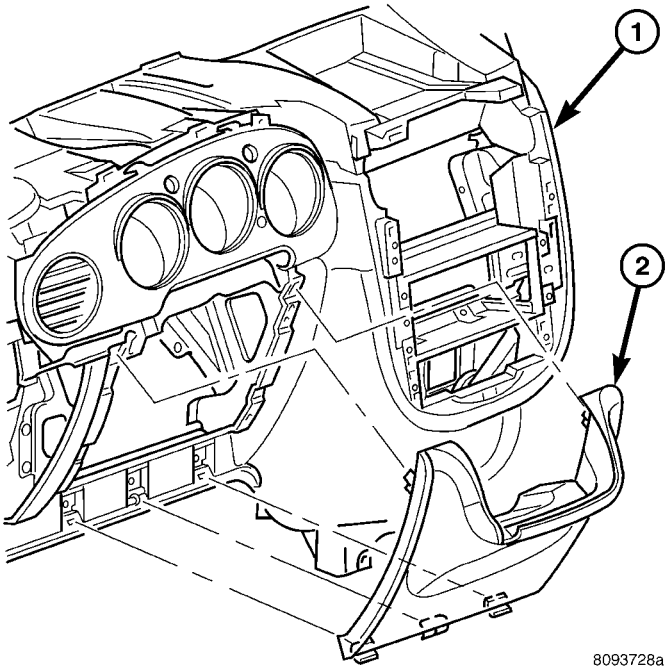

Fig. 75 Lower Instrument Panel Bezel

1 - INSTRUMENT PANEL
2 - INSTRUMENT PANEL STEERING COLUMN COVER

(15) Install PDC bracket into position.

(16) Raise vehicle on hoist.

MASTER CYLINDER - RHD (Continued)

(17) Connect battery negative cable.
(18) Install air cleaner assembly (Fig. 76).

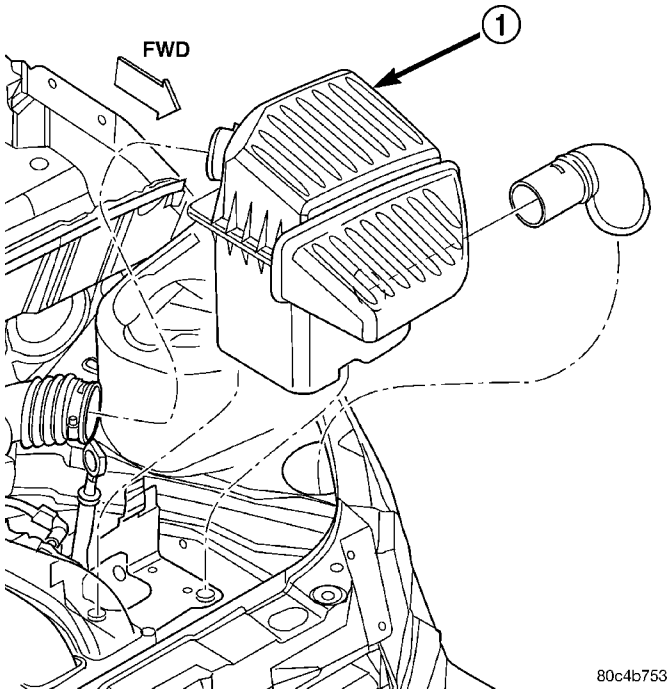

Fig. 76 Air Cleaner Assembly Removal/Installation

1 - AIR CLEANER ASSEMBLY

(19) Verify that brake master cylinder reservoir is full. Top off with DOT 3 brake fluid if necessary.

(20) Actuate clutch pedal a minimum of fifty times to allow any air ingested into the system to vent to the master cylinder reservoir. If residual air becomes trapped in the system, it is necessary to bleed the clutch hydraulic system. (Refer to 6 - CLUTCH - STANDARD PROCEDURE)

(21) Verify proper clutch release system operation.

MODULAR CLUTCH

DESCRIPTION

2.4L MODELS (Except Turbo)

The modular clutch assembly (Fig. 77) is located between the engine and manual transaxle in the transaxle bellhousing, and is responsible for transmitting engine power to the transaxle. The modular clutch is an assembly which incorporates a self-adjusting design and consists of the following components:

- Flywheel
- Clutch Disc
- Pressure Plate
- Diaphragm Spring
- Adjusting Ring
- Sensor
- Cover

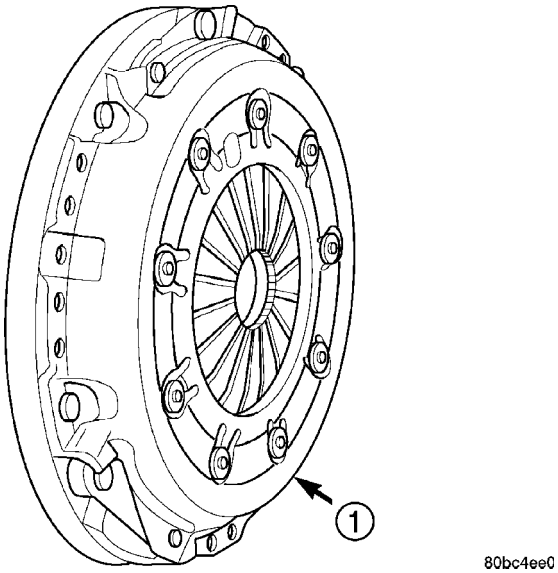

Fig. 77 Modular Clutch Assembly—Typical

1 - MODULAR CLUTCH ASSEMBLY

2.4L TURBO MODELS

Models equipped with the 2.4L Turbo Engine option also utilize a modular clutch assembly, however, this application incorporates a Dual-Mass Flywheel (DMF), is not of a self-adjusting design, and is serviceable.

MODULAR CLUTCH (Continued)

OPERATION

The modular clutch assembly is designed to transmit power from the engine to the manual transaxle. This is accomplished by the friction and clamping force generated when the spring loaded pressure plate locks the clutch disc to the flywheel (Fig. 78). The clutch disc, which is splined to the transaxle input shaft, transmits power until the center of the diaphragm spring is depressed, and the clamp force is removed from the disc. The self -adjusting feature of this clutch assembly relies on the sensor ring and the adjuster ring (Fig. 79) , which works its way around a ramped clutch cover, taking up clearance as the clutch disc wears and maintaining diaphragm spring force throughout the life of the clutch. The primary benefits of this design are reduced pedal effort, constant release load over clutch life, and extended clutch life.

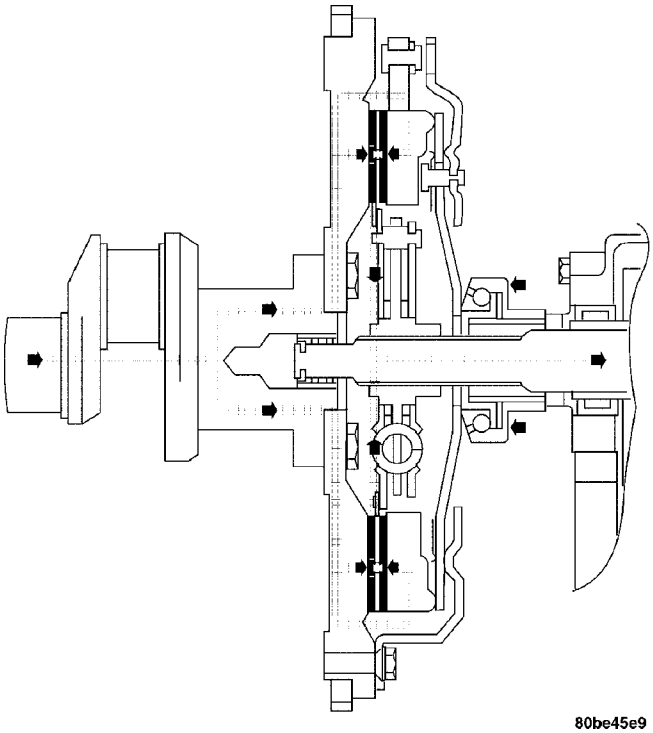

Fig. 78 Clutch Coupling Powerflow - Typical

REMOVAL

(1) Remove transaxle from vehicle. (Refer to 21 - TRANSMISSION/TRANSAXLE/MANUAL - REMOVAL)

(2) Remove modular clutch assembly (Fig. 80) from transaxle input shaft.

(3) **2.4L Turbo models:** Disassemble modular clutch assembly. Remove six (6) pressure plate-to-flywheel bolts (Fig. 81). Remove pressure plate and disc from flywheel.

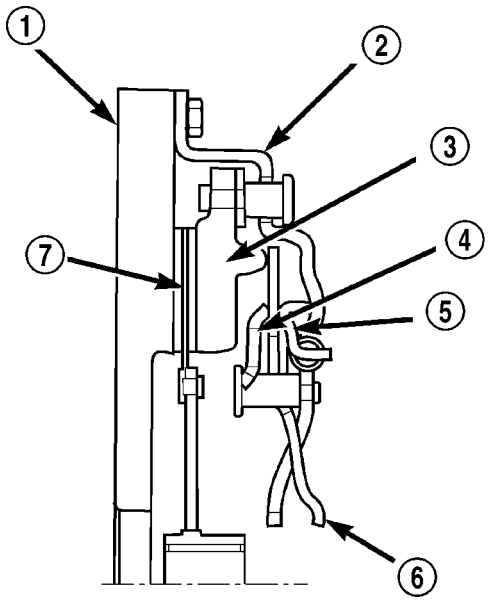

Fig. 79 Modular Clutch Assembly Components—Typical

1 - FLYWHEEL
2 - COVER
3 - PRESSURE PLATE
4 - SENSOR RING
5 - ADJUSTING RING
6 - DIAPHRAGM SPRING
7 - DISC

INSPECTION

Fluid contamination is a frequent cause of clutch malfunctions. Oil, grease, water, or other fluids on the clutch contact surfaces will cause faulty operation.

During inspection, note if any components are contaminated. Look for evidence of oil, grease, or water/road splash on clutch components.

OIL CONTAMINATION

Oil contamination indicates a leak at the rear main seal and/or transaxle input shaft. Oil leaks produce a residue of oil on the transaxle housing interior, clutch cover and flywheel. Heat buildup caused by slippage can bake the oil residue onto the components. This glaze-like residue ranges in color from amber to black.

GREASE CONTAMINATION

Grease contamination is usually a product of overlubrication. During clutch service, apply only a small amount of grease to the input shaft splines. Excess grease may be thrown off during operation, contaminating the disc.

MODULAR CLUTCH (Continued)

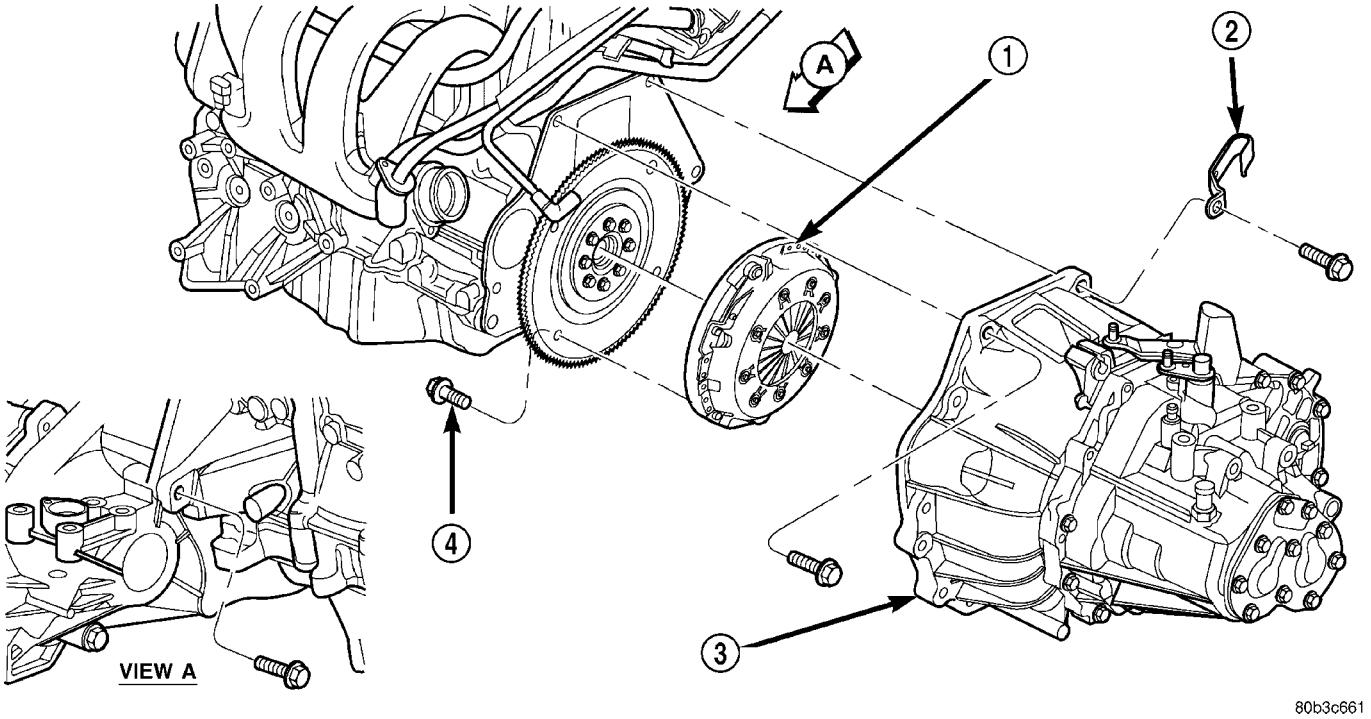

Fig. 80 Modular Clutch Assembly—Typical

1 - MODULAR CLUTCH ASSEMBLY
2 - CLIP
3 - TRANSAXLE
4 - CLUTCH MODULE BOLT (4)

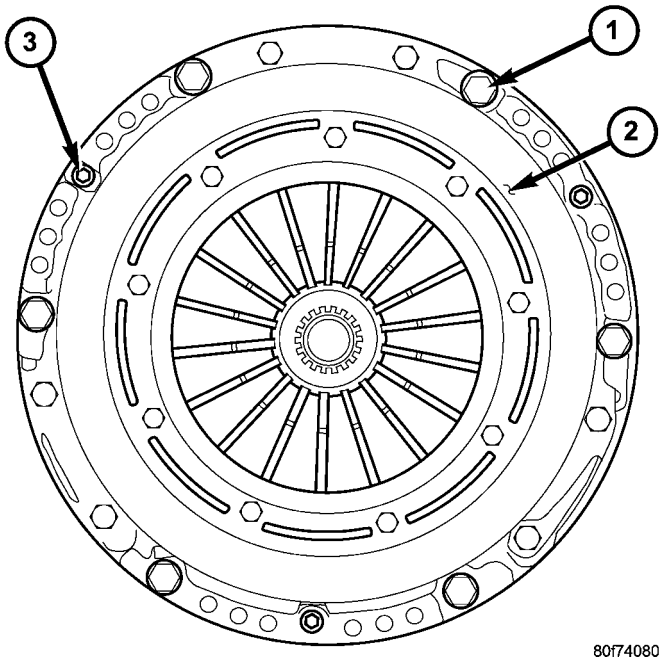

Fig. 81 Pressure Plate-to-Flywheel Bolts—Turbo

1 - BOLT (6)
2 - PRESSURE PLATE
3 - DOWEL

ROAD SPLASH/WATER CONTAMINATION

Road splash contamination is usually caused by driving the vehicle through deep water puddles. Water can be forced into the clutch housing, causing clutch components to become contaminated. Facing of disc will absorb moisture and bond to the flywheel and/or, pressure plate, if vehicle is allowed to stand for some time before use. If this condition occurs, replacement of clutch assembly may be required. Drive the vehicle until normal clutch operating temperature has been obtained. This will dry off disc assembly, pressure plate, and flywheel.

MODULAR CLUTCH (Continued)

INSTALLATION

(1) **2.4L Turbo models:** Install clutch disc to flywheel with “Flywheel Side” oriented towards flywheel. Align clutch disc to flywheel by ensuring equal distance between disc and flywheel lip exists in three places as shown in (Fig. 82). Install pressure plate to flywheel, locating on dowels (Fig. 81) and making sure not to disturb clutch disc. Install and torque six (6) pressure plate-to-flywheel bolts to 28 N·m (250 in. lbs.). Visually verify clutch disc alignment.

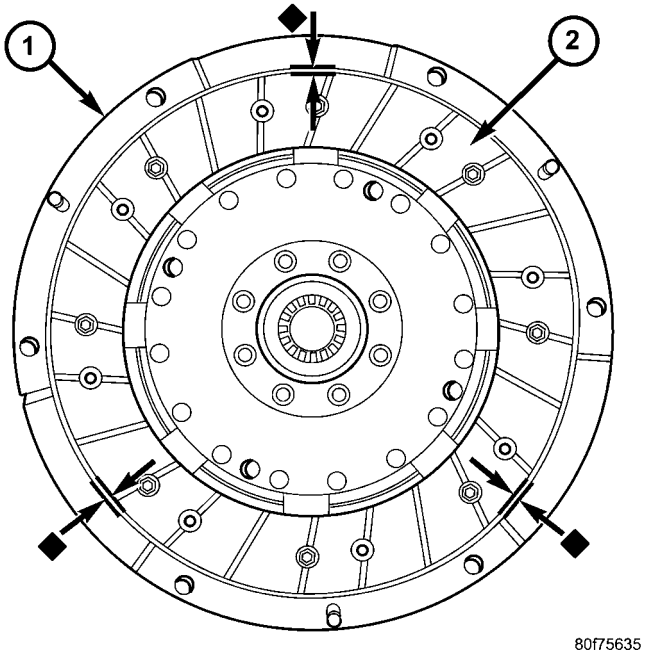

Fig. 82 Clutch Disc-to-Flywheel Orientation

1 - FLYWHEEL
2 - CLUTCH DISC
◇ - EQUAL DISTANCE FOR ALIGNMENT

(2) **All models:** Install clutch module (Fig. 80) onto input shaft.

(3) Install transaxle into vehicle. (Refer to 21 - TRANSMISSION/TRANSAXLE/MANUAL - INSTALLATION)

SLAVE CYLINDER

DESCRIPTION

1.6/2.4L MODELS (Except Diesel & Turbo)

The clutch slave cylinder consists of a hydraulic piston and cylinder, seal and return spring. It is fastened to the transaxle bellhousing as shown in (Fig. 83) (Fig. 84). The slave cylinder is connected to the clutch master cylinder hydraulic pipe, which is retained to the cylinder by a pair of retainer clips, and utilizes a bleed port to facilitate the removal of air from the system.

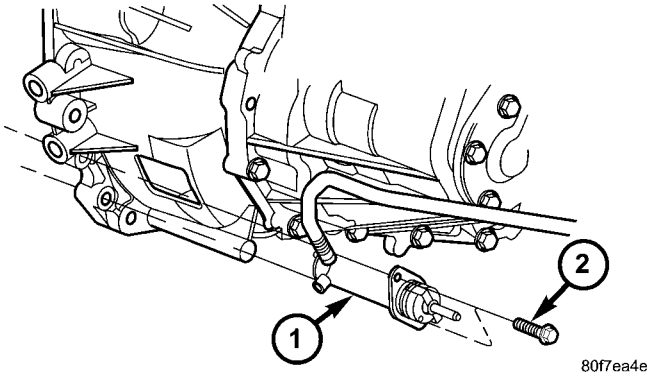

Fig. 83 Clutch Slave Cylinder at Transaxle- 1.6L Models

2 - BOLT

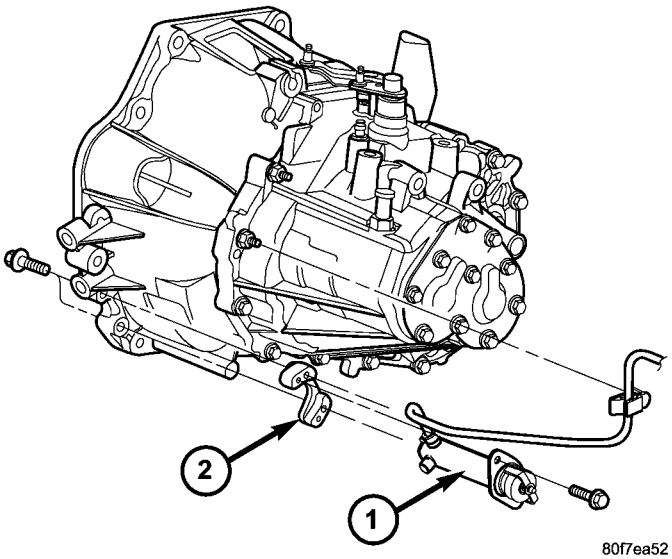

Fig. 84 Clutch Slave Cylinder at Transaxle- 2.4L Models

1 - SLAVE CYLINDER
2 - BRACKET

SLAVE CYLINDER (Continued)

DIESEL AND TURBO MODELS

The clutch release system utilizes a slave cylinder of a concentric design, having all components fixed about the same axis. The concentric slave cylinder (CSC) is mounted to the inside of the clutch bellhousing (Fig. 85), and is serviced only as an assembly.

The concentric design permits high efficiency, resulting in low and consistent pedal effort, as well as automatic adjustment to compensate for clutch disc wear.

The CSC is a self-contained unit, consisting of a main body and piston, spring, integrated release bearing, and a rubber boot (Fig. 86).

REMOVAL

REMOVAL—1.6/2.4L (Except Diesel and Turbo)

NOTE: To prevent drainage of clutch master cylinder assembly upon slave cylinder removal, it is necessary to make sure brake master cylinder fluid level is full and reservoir cap is installed tight.

(1) Verify proper brake fluid level and top off if necessary. Install and tighten brake master cylinder cap to prevent clutch hydraulic system drainage.

(2) Raise vehicle on hoist.

(3) Using suitable screwdriver, release both slave cylinder hydraulic line snap ring retainers (Fig. 87). Do not separate at this time.

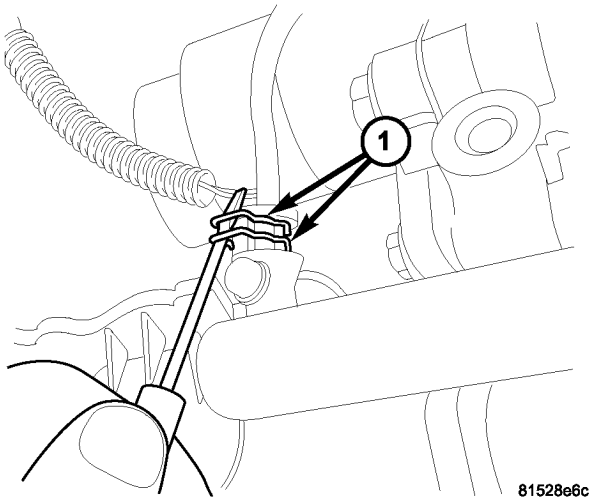

Fig. 87 Hydraulic Tube Retainer Clips

1 - RETAINER CLIPS

SLAVE CYLINDER (Continued)

(4) Remove slave cylinder-to-transaxle mounting bolts (Fig. 88) (Fig. 89).

(5) Have replacement slave cylinder ready. Remove slave cylinder from transaxle and separate from hydraulic tube. Quickly attach replacement slave cylinder to plumbing and secure with both retaining clips.

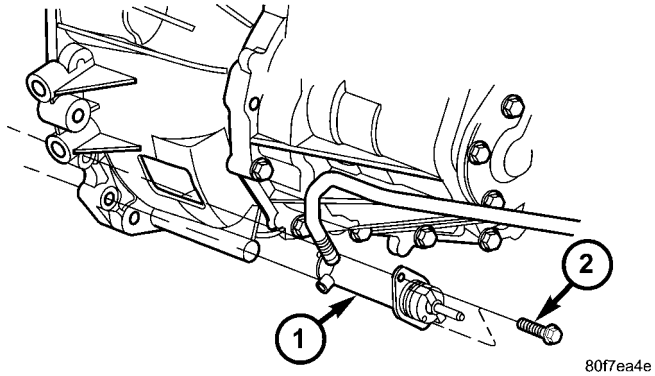

Fig. 88 Clutch Slave Cylinder at Transaxle—1.6L Models

1 - SLAVE CYLINDER
2 - BOLT

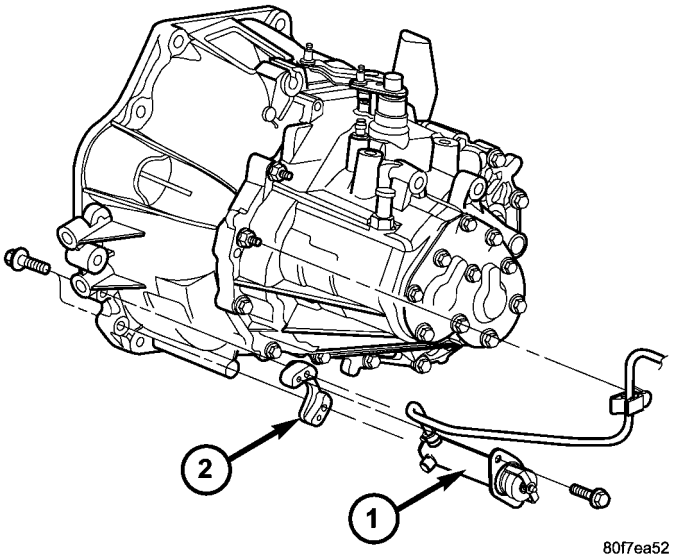

Fig. 89 Clutch Slave Cylinder at Transaxle—2.4L Models

1 - SLAVE CYLINDER
2 - BRACKET

REMOVAL—DIESEL AND TURBO MODELS

NOTE: To prevent drainage of clutch master cylinder assembly upon slave cylinder removal, it is necessary to make sure brake master cylinder fluid level is full and reservoir cap is installed tight.

(1) Remove transaxle from vehicle. (Refer to 21 - TRANSMISSION/TRANSAXLE/MANUAL - REMOVAL)

(2) Remove four (4) slave cylinder-to-clutch bell-housing bolts and remove slave cylinder from transaxle (Fig. 90).

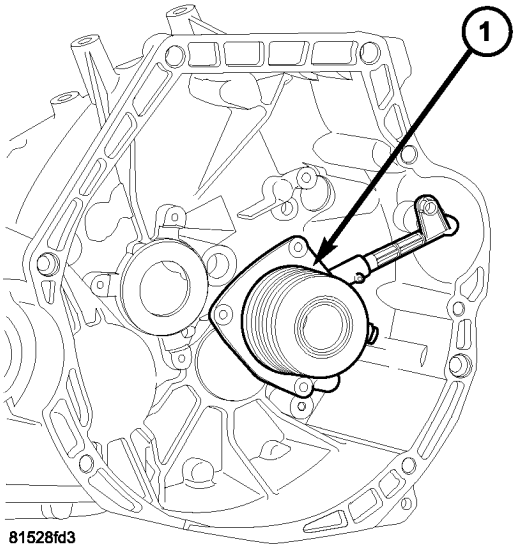

Fig. 90 CSC Removal/Installation

1 - CONCENTRIC SLAVE CYLINDER

INSTALLATION

INSTALLATION—1.6/2.4L MODELS (Except Diesel and Turbo)

(1) Connect slave cylinder to hydraulic tube. Press both retainer clips to secure tube in cylinder (Fig. 91).

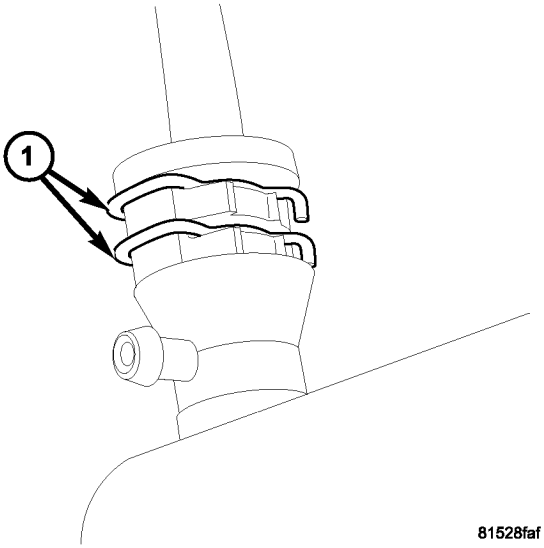

Fig. 91 Hydraulic Tube Retaining Clips

1 - RETAINER CLIPS

SLAVE CYLINDER (Continued)

(2) Install the slave cylinder assembly into position on transaxle (Fig. 92) (Fig. 93).

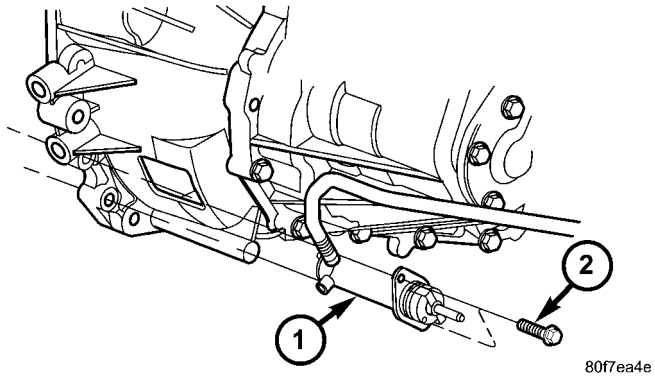

Fig. 92 Clutch Slave Cylinder at Transaxle—1.6L Models

1 - SLAVE CYLINDER
2 - BOLT

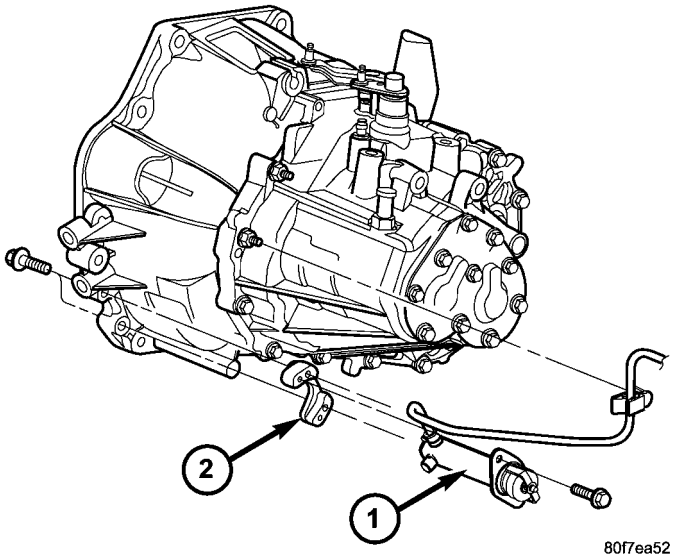

Fig. 93 Clutch Slave Cylinder at Transaxle—2.4L Models

1 - SLAVE CYLINDER
2 - BRACKET

(3) Tighten slave cylinder-to-transaxle bolts to 19 N·m (168 in. lbs.) on 2.4L applications, and 12 N·m (105 in. lbs.) torque on 1.6L applications.

(4) Lower vehicle.

(5) Verify brake master cylinder reservoir is full. Top off with DOT 3 brake fluid if necessary.

(6) Bleed clutch hydraulic system (Refer to 6 - CLUTCH - STANDARD PROCEDURE).

(7) Verify proper clutch release system operation.

INSTALLATION—DIESEL AND TURBO MODELS

(1) Install slave cylinder to transaxle using new bolts (Fig. 94).

NOTE: Torque three CSC body screws first, then fluid tube attachment.

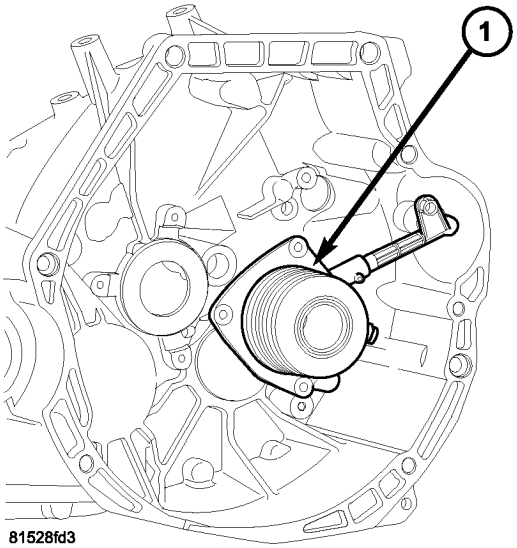

Fig. 94 CSC Removal/Installation

1 - CONCENTRIC SLAVE CYLINDER

(2) Torque slave cylinder-to-case bolts in three steps:

1. 2 N·m (18 in. lbs.)
2. 5 N·m (44 in. lbs.)
3. 8.4 N·m (74 in. lbs.)

(3) Install transaxle. (Refer to 21 - TRANSMISSION/TRANSAXLE/MANUAL - INSTALLATION)

(4) Bleed clutch hydraulic system. (Refer to 6 - CLUTCH - STANDARD PROCEDURE)

ACCESSORY DRIVE - 1.6L SOHC

DESCRIPTION

The accessory drive consists of one Poly-V type drive belt that drives the generator, power steering/water pump, and air conditioning compressor (if equipped). The belt tension is controlled by an automatic belt tensioner. If equipped with air conditioning, the accessory drive also has an idler pulley (Fig. 1) or (Fig. 2).

DIAGNOSIS AND TESTING - ACCESSORY DRIVE BELT DIAGNOSIS

CONDITION	POSSIBLE CAUSE	CORRECTION
BELT SLIPPAGE	1. Belt slipping because of insufficient tension.	1. Replace accessory drive belt tensioner.
	2. Belt excessively glazed or hardened from heat and excessive slippage.	2. Replace belt.
	3. Incorrect belt.	3. Replace belt.
	4. Driven component bearing failure.	4. Replace faulty component.
	5. Belt or pulley subjected to substance (belt dressing, oil, ethylene glycol) that has reduced friction.	5. Replace belt and clean pulleys.
BELT NOISE (OBJECTIONABLE SQUEAL, SQUEAK, OR RUMBLE)	1. Belt slippage.	1. Refer to BELT SLIPPAGE above.
	2. Foreign material imbedded in belt.	2. Replace belt.
	3. Non-uniform belt.	3. Replace belt.
	4. Non-uniform groove or eccentric/bent pulley.	4. Replace pulley(s).
	5. Bearing noise.	5. Locate and repair.

ACCESSORY DRIVE - 1.6L SOHC (Continued)

CONDITION	POSSIBLE CAUSE	CORRECTION
BELT ROLLED OVER IN GROOVE OR BELT JUMPS OFF	1. Broken cord in belt.	1. Replace belt.
	2. Belt tension too loose, or too tight.	2. Replace accessory drive belt tensioner.
	3. Non-uniform grooves or eccentric/bent pulley.	3. Replace pulley(s).
	4. Foreign object(s) in grooves.	4. Remove foreign object(s) in groove.

ACCESSORY DRIVE BELT

REMOVAL

(1) Disconnect negative battery cable.

(2) Insert a 1/2” drive breaker bar into the square opening of the accessory drive belt tensioner.

(3) Rotate accessory drive belt tensioner counter-clockwise until accessory drive belt can be removed from pulleys (Fig. 1) or (Fig. 2). Remove accessory drive belt.

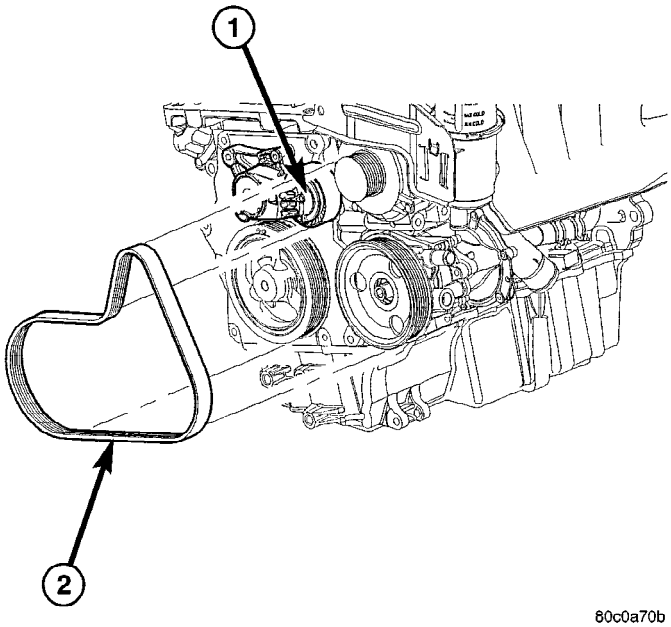

Fig. 1 Accessory Drive Belt - without A/C

1 - ACCESSORY DRIVE BELT TENSIONER
2 - ACCESSORY DRIVE BELT

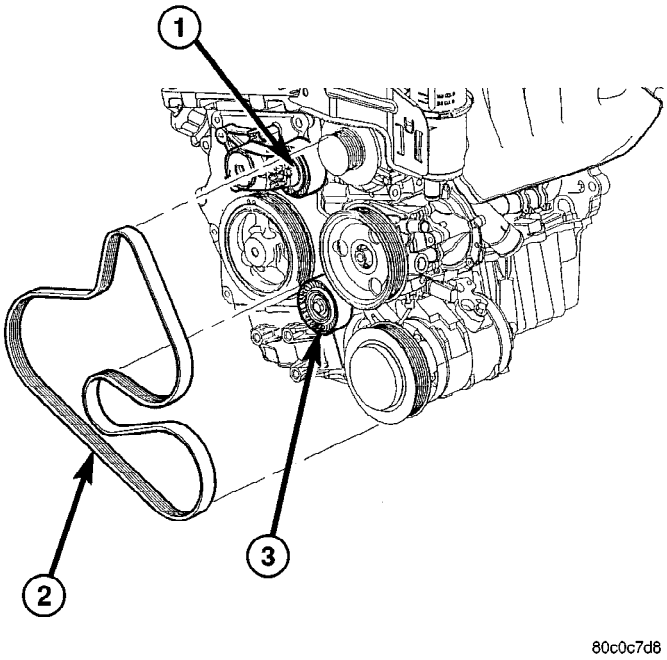

Fig. 2 Accessory Drive Belt - with A/C

1 - ACCESSORY DRIVE BELT TENSIONER
2 - ACCESSORY DRIVE BELT
3 - IDLER PULLEY

CLEANING

Clean all foreign debris from belt pulley grooves. The belt pulleys must be free of oil, grease, and coolants before installing the drive belt.

ACCESSORY DRIVE BELT (Continued)

INSPECTION

New developments in belt technology allow the belt to greatly increase its life expectancy. Unless the belt exhibits one of the following conditions do not replace the belt.

- Excessive wear
- Frayed cords
- Severe glazing

Poly-V Belt system may develop minor cracks across the ribbed side (due to reverse bending). These minor cracks are considered normal and acceptable. Parallel cracks are not (Fig. 3).

NOTE: Do not use any type of belt dressing or restorer on Poly-V Belts.

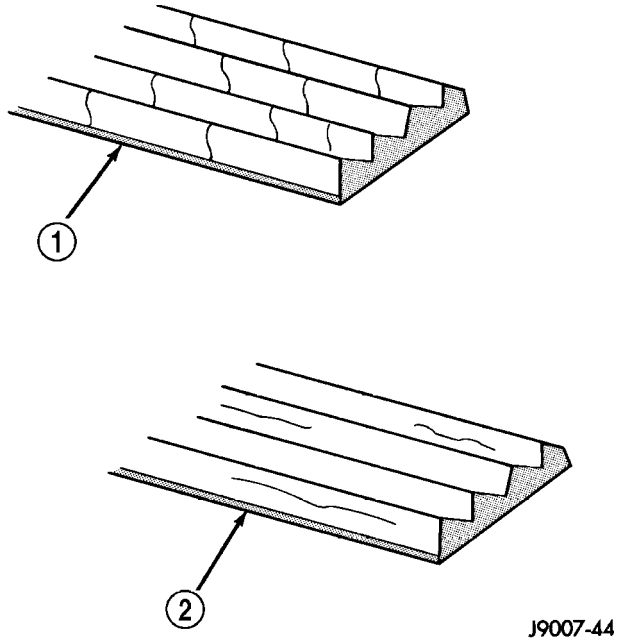

Fig. 3 Drive Belt Inspection

1 - NORMAL CRACKS - BELT OK
2 - NOT NORMAL CRACKS - REPLACE BELT

INSTALLATION

NOTE: When installing drive belt on the pulleys, make sure that belt is properly routed and all V-grooves make proper contact with pulley grooves.

(1) Install belt around all the pulleys except for the generator pulley (Fig. 1) or (Fig. 2).

(2) Rotate accessory drive belt tensioner counterclockwise until accessory drive belt can be installed on the generator pulley. Release spring tension onto belt.

(3) Remove breaker bar from accessory drive belt tensioner.

(4) Connect negative battery cable.

ACCESSORY DRIVE BELT TENSIONER

REMOVAL

(1) Disconnect negative battery cable.

(2) Raise vehicle on hoist.

(3) Remove belt splash shield.

(4) Remove accessory drive belt (Refer to 7 - COOLING/ACCESSORY DRIVE/DRIVE BELTS - REMOVAL).

(5) Remove fasteners securing accessory drive belt tensioner to timing chain cover (Fig. 4). Remove accessory drive belt tensioner.

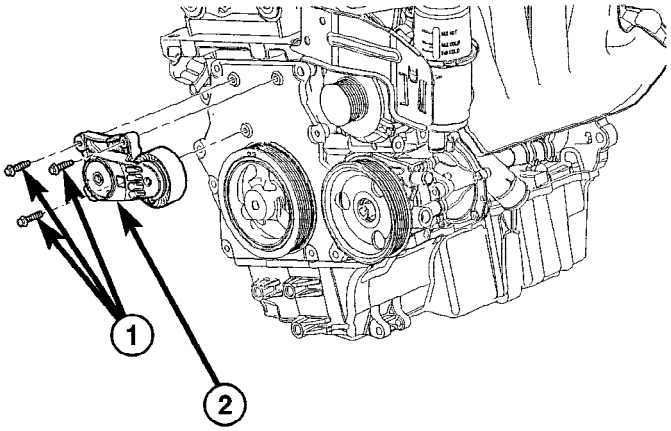

Fig. 4 Accessory Drive Belt Tensioner

1 - ACCESSORY DRIVE BELT TENSIONER FASTENERS
2 - ACCESSORY DRIVE BELT TENSIONER

INSTALLATION

(1) Position accessory drive belt tensioner in mounting position. Install fasteners securing accessory drive belt tensioner to timing chain cover. Torque fasteners to 12 N·m (105 in. lbs.) (Fig. 4).

(2) Install accessory drive belt (Refer to 7 - COOLING/ACCESSORY DRIVE/DRIVE BELTS - INSTALLATION).

(3) Install belt splash shield.

(4) Lower vehicle.

(5) Connect negative battery cable.

IDLER PULLEY

REMOVAL

(1) Disconnect negative battery cable.
(2) Raise vehicle on hoist.
(3) Remove belt splash shield.
(4) Remove accessory drive belt (Refer to 7 - COOLING/ACCESSORY DRIVE/DRIVE BELTS - REMOVAL).
(5) Remove fastener securing idler pulley to front of engine (Fig. 5). Remove idler pulley.

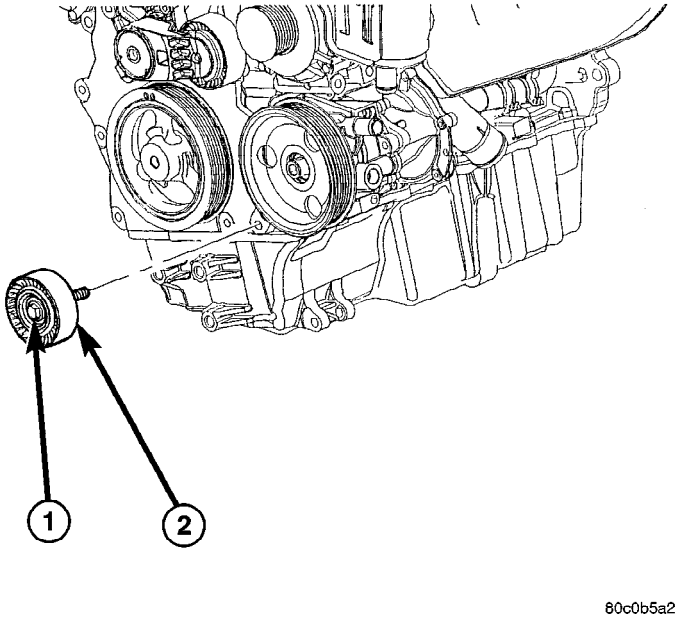

Fig. 5 Idler Pulley

1 - IDLER PULLEY FASTENER
2 - IDLER PULLEY

INSTALLATION

(1) Position pulley in mounting position. Install fastener securing idler pulley to front of engine. Torque fastener to 28 N·m (250 in. lbs.) (Fig. 5).
(2) Install accessory drive belt (Refer to 7 - COOLING/ACCESSORY DRIVE/DRIVE BELTS - INSTALLATION).
(3) Install belt splash shield.
(4) Lower vehicle.
(5) Connect negative battery cable.

DRIVE BELTS

DESCRIPTION

The accessory drive consist of two Poly-V type drive belts (Fig. 1). One belt drives the generator, the other drives the power steering pump and air conditioning compressor (if equipped). The power steering/air conditioning belt is tensioned by an automatically controlled belt tensioner. The generator belt is manually tensioned using an adjusting bolt and a locking nut.

DRIVE BELTS (Continued)

DIAGNOSIS AND TESTING

ACCESSORY DRIVE BELTS

CONDITION	POSSIBLE CAUSE	CORRECTION
BELT SLIPPAGE	1. Belt slipping because of insufficient tension.	1. Retension generator belt. Replace the power steering belt's automatic belt tensioner.
	2. Belt excessively glazed or hardened from heat and excessive slippage.	2. Replace belt.
	3. Incorrect belt.	3. Replace belt.
	4. Driven component bearing failure.	4. Replace faulty component.
	5. Belt or pulley subjected to substance (belt dressing, oil, ethylene glycol) that has reduced friction.	5. Replace belt and clean pulleys.
BELT NOISE (OBJECTIONABLE SQUEAL, SQUEAK, OR RUMBLE)	1. Belt slippage.	1. Retension generator belt, replace belt, or automatic belt tensioner.
	2. Foreign material imbedded in belt.	2. Replace belt.
	3. Non-uniform belt.	3. Replace belt.
	4. Misaligned pulley(s).	4. Align accessories.
	5. Non-uniform groove or eccentric pulley.	5. Replace pulley(s).
	6. Bearing noise.	6. Locate and repair.
BELT ROLLED OVER IN GROOVE OR BELT JUMPS OFF	1. Broken cord in belt.	1. Replace belt.
	2. Belt tension too loose, or too tight.	2. Retension generator belt. Replace the power steering belt's automatic belt tensioner.
	3. Misaligned pulleys.	3. Align accessories.
	4. Non-uniform grooves or eccentric pulley.	4. Replace pulley(s).
	5. Foreign object(s) in grooves.	5. Remove foreign objects in groove.

DRIVE BELTS (Continued)

REMOVAL

POWER STEERING PUMP/AIR CONDITIONING COMPRESSOR BELT

(1) Remove belt splash shield (Fig. 2).

(2) Using a wrench, rotate belt tensioner clockwise (Fig. 3) until belt can be removed from power steering pump pulley. Gently, release spring tension on tensioner.

(3) Remove belt (Fig. 4).

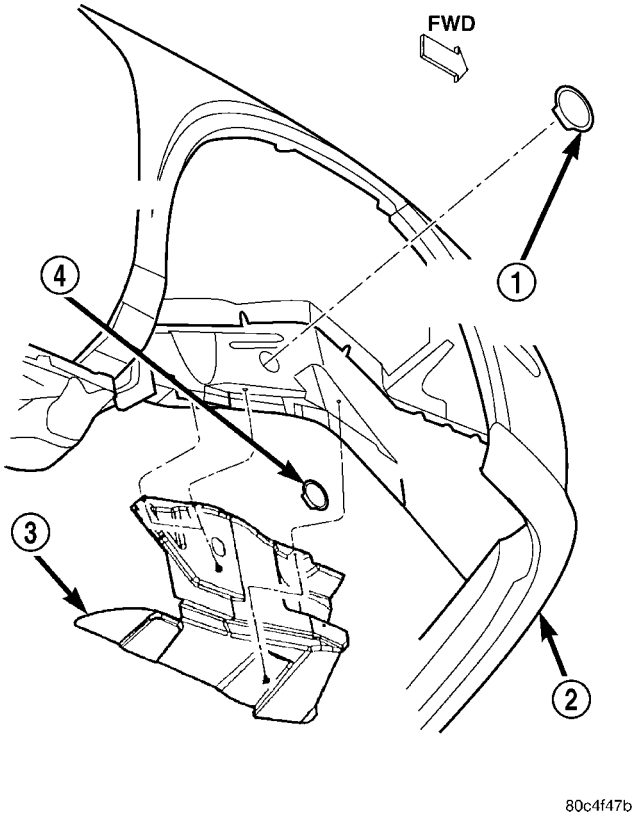

Fig. 2 Splash Shield

1 - RIGHT MOUNT BOLT ACCESS PLUG

4 - CRANKSHAFT BOLT ACCESS PLUG

GENERATOR BELT

(1) Remove power steering pump/air conditioning compressor drive belt.

(2) Loosen pivot bolt, then locking nut and adjusting bolt (Fig. 5).

(3) Remove generator belt.

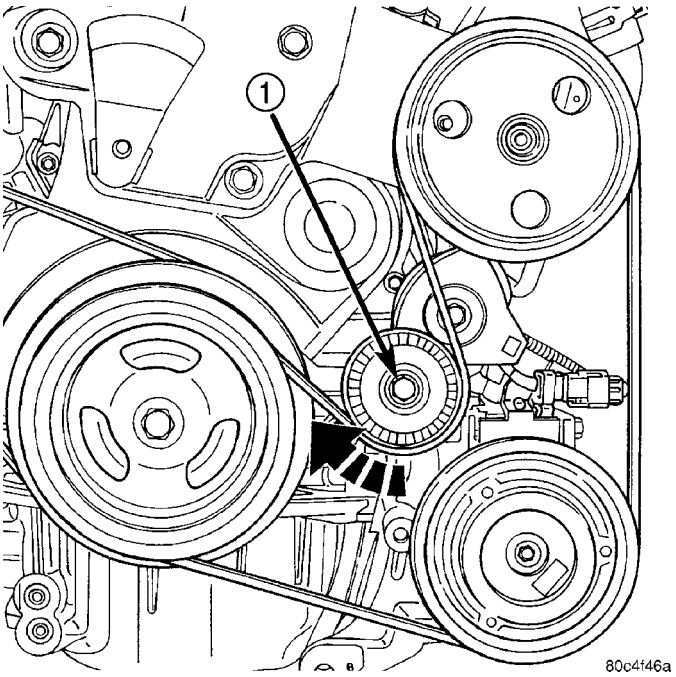

Fig. 3 Accessory Belt—Removing

1 - BOLT

CLEANING

Clean all foreign debris from belt pulley grooves. The belt pulleys must be free of oil, grease, and coolants before installing the drive belt.

INSPECTION

New developments in belt technology allow the belt to greatly increase its life expectancy. Unless the belt exhibits one of the following conditions do not replace the belt.

- Excessive wear
- Frayed cords
- Severe glazing

Poly-V Belt system may develop minor cracks across the ribbed side (due to reverse bending). These minor cracks are considered normal and acceptable. Parallel cracks are not (Fig. 6).

NOTE: Do not use any type of belt dressing or restorer on Poly-V Belts.

DRIVE BELTS (Continued)

INSTALLATION

GENERATOR BELT

NOTE: When installing drive belt onto pulleys, make sure that belt is properly routed and all V-grooves make proper contact with pulley grooves.

(1) Install belt and/or adjust belt tension by tightening adjusting bolt. Adjust belt to specification shown in Belt Tension Chart.

(2) Check belt tension using Special Tool 8371 – Belt Tension Gauge Adapter, and the DRBIII® using the following procedures:

WARNING: DO NOT CHECK BELT TENSION WITH ENGINE RUNNING.

(a) Connect 8371 to the DRBIII® following the instructions provided in tool kit.

(b) Place end of microphone probe approximately 2.54 cm (1 in.) from belt at one of the belt center span locations shown in (Fig. 7).

(c) Pluck the belt a minimum of 3 times. (Use your finger or other suitable object)

(d) The frequency of the belt in hertz (Hz) will display on DRBIII® screen.

(e) Adjust belt to obtain proper frequency (tension). Refer to the belt tension chart for specifications.

(3) Tighten pivot bolt to 54 N·m (40 ft. lbs.) and locking nut to 54 N·m (40 ft. lbs.) (Fig. 5).

(4) Install power steering pump/air conditioning compressor drive belt.

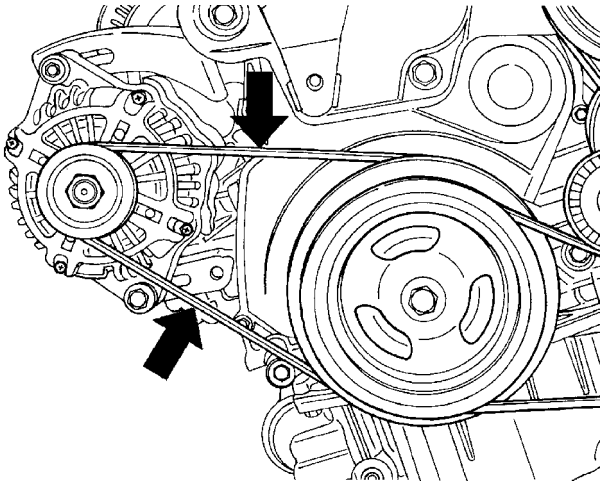

Fig. 7 Belt Center Span

BELT TENSION CHART

Accessory Drive Belt	Belt Tension	
Power Steering Pump and A/C Compressor	Dynamic Tensioner	
Generator	New 135 lb. Used 100 lb.	235-247 Hz 207-217 Hz

POWER STEERING PUMP/AIR CONDITIONING COMPRESSOR BELT

NOTE: When installing drive belt onto pulleys, make sure that belt is properly routed and all V-grooves make proper contact with pulley grooves.

(1) Install belt (Fig. 4) over all pulleys except for the power steering pump pulley.

(2) Using a wrench, rotate belt tensioner clockwise (Fig. 3) until belt can be installed onto power steering pump pulley. Release spring tension onto belt.

(3) After belt is installed, inspect belt length indicator marks (Fig. 8). The indicator mark should be within the minimum belt length and maximum belt length marks. On a new belt, the indicator mark should align approximately with the nominal belt length mark.

(4) Install belt splash shield (Fig. 2).

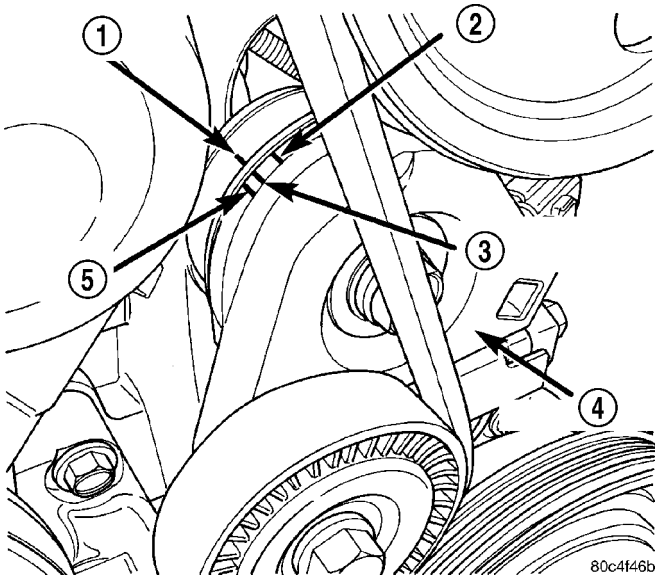

Fig. 8 Belt Length Indicator Marks

1 - BELT LENGTH INDICATOR
2 - MAXIMUM LENGTH
3 - NOMINAL LENGTH
4 - TENSIONER
5 - MINIMUM LENGTH

DRIVE BELTS (Continued)

ADJUSTMENTS

BELT TENSION

For belt tension adjustment procedure, (Refer to 7 - COOLING/ACCESSORY DRIVE/DRIVE BELTS - INSTALLATION).

AUTOMATIC BELT TENSIONER AND PULLEY

DESCRIPTION

The automatic belt tensioner (Fig. 9) maintains proper tension on the power steering and air conditioning belt. The tensioner pulley can be serviced separately.

NOTE: Tensioner arm should move freely and maintain 33–46 lb. tension on belt.

REMOVAL

(1) Remove power steering/air conditioning compressor belt (Refer to 7 - COOLING/ACCESSORY DRIVE/DRIVE BELTS - REMOVAL).

(2) Remove tensioner mounting bolt and remove tensioner assembly (Fig. 9).

(3) Remove tensioner pulley, if replacing the pulley.

INSTALLATION

(1) Install tensioner pulley and bolt, if removed. Tighten bolt to 27 N·m (20 ft. lbs.).

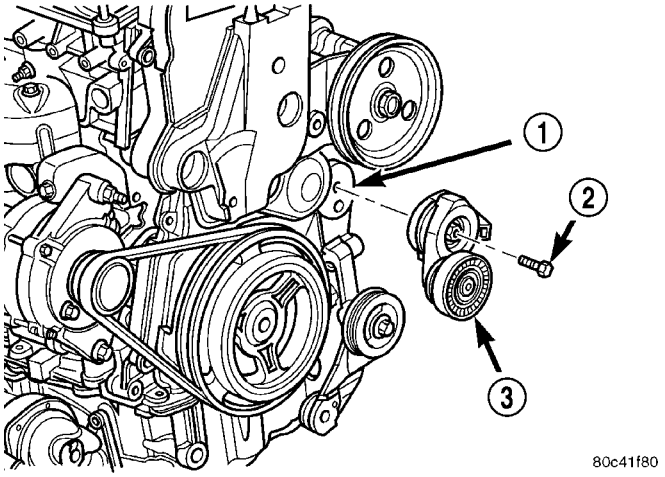

Fig. 9 Automatic Belt Tensioner

1 - TORQUE STRUT BRACKET
2 - BOLT
3 - AUTOMATIC BELT TENSIONER ASSEMBLY

(2) Install tensioner assembly to engine and tighten bolt to 54 N·m (40 ft. lbs.) (Fig. 9).

(3) Install power steering/air conditioning compressor belt (Refer to 7 - COOLING/ACCESSORY DRIVE/DRIVE BELTS - INSTALLATION).

NOTE: Tensioner arm should move freely and maintain 33–46 lb. tension on belt.

ENGINE - 1.6L SOHC

DESCRIPTION

The cooling system consists of an engine cooling module, thermostat, coolant, hoses, clamps, coolant recovery container, and a water pump to circulate the coolant. The engine cooling module may consist of a radiator, electric fan, radiator pressure cap, transmission oil cooler and lines (auto transmission equipped vehicles), and an air conditioning condenser (air conditioning equipped vehicles).

OPERATION

The primary purpose of a cooling system is to maintain engine temperature in a range that will provide satisfactory engine performance and emission levels under all expected driving conditions. It also provides hot water (coolant) for heater performance and cooling for automatic transmission oil. It does this by transferring heat from engine metal to coolant, moving this heated coolant to the radiator, and then transferring this heat to the ambient air.

The coolant flow circuit is shown in (Fig. 1).

ENGINE - 1.6L SOHC (Continued)

DIAGNOSIS AND TESTING

DIAGNOSIS AND TESTING - COOLING SYSTEM AERATION

If coolant level drops below a certain point, aeration will occur drawing air into the water pump resulting in the following:

- High reading shown on the temperature gauge.
- Loss of coolant flow through the heater core.
- Corrosion in the cooling system.
- Transmission oil will become hotter (automatic transmission equipped vehicles).
- Water pump seal may run dry, increasing the risk of premature seal failure.
- Combustion gas leaks into the coolant can also cause the above problems.

DIAGNOSIS AND TESTING - COOLING SYSTEM DEAERATION

As air is removed from the cooling system, it gathers in the coolant recovery container. This pressure is released into the atmosphere through the pressure valve located in the radiator pressure cap when pressure reaches 96 - 124 kPa (14 - 18 psi). This air is replaced with coolant from the coolant recovery container.

NOTE: Deaeration does not occur at engine idle, higher engine speeds are required. Normal driving will deaerate cooling system.

To effectively deaerate the system, multiple thermal cycles of the system may be required.

DIAGNOSIS AND TESTING - COOLING SYSTEM FLOW CHECK

WARNING: DO NOT REMOVE THE COOLING SYSTEM PRESSURE CAP WITH THE SYSTEM HOT AND UNDER PRESSURE BECAUSE SERIOUS BURNS FROM COOLANT CAN OCCUR.

To determine whether coolant is flowing through the cooling system, use one of the following procedures:

- If engine is cold, idle engine until normal operating temperature is reached. Then feel the upper radiator hose. If it is hot, coolant is circulating.
- Remove pressure cap when engine is cold, remove small amount of coolant. Idle engine until thermostat opens, you should observe coolant flow while looking down the filler neck. Once flow is detected install the pressure cap.

DIAGNOSIS AND TESTING - COOLING SYSTEM LEAK TESTING

WARNING: IF VEHICLE HAS BEEN RUN RECENTLY, WAIT 15 MINUTES BEFORE REMOVING PRESSURE CAP. PLACE A SHOP TOWEL OVER THE CAP, AND WITHOUT PUSHING DOWN, ROTATE IT COUNTER-CLOCKWISE TO THE FIRST STOP. ALLOW FLUIDS TO ESCAPE THROUGH THE OVERFLOW TUBE. WHEN THE SYSTEM STOPS PUSHING COOLANT AND STEAM INTO THE COOLANT RECOVERY CONTAINER AND PRESSURE DROPS, PUSH DOWN ON THE CAP AND REMOVE IT COMPLETELY. SQUEEZING THE RADIATOR INLET HOSE WITH A SHOP TOWEL (TO CHECK PRESSURE) BEFORE AND AFTER TURNING TO THE FIRST STOP IS RECOMMENDED.

With engine not running, wipe the coolant filler neck sealing seat clean. The radiator should be full.

Attach a cooling system pressure tester (Tool 7700 or equivalent) to the coolant filler neck, as shown in (Fig. 2) and apply 104 kPa (15 psi) pressure. If the pressure drops more than 2 psi in 2 minutes inspect all points for external leaks.

All hoses, radiator and heater, should be moved while at 104 kPa (15 psi) since some leaks occur while driving due to engine movement, etc.

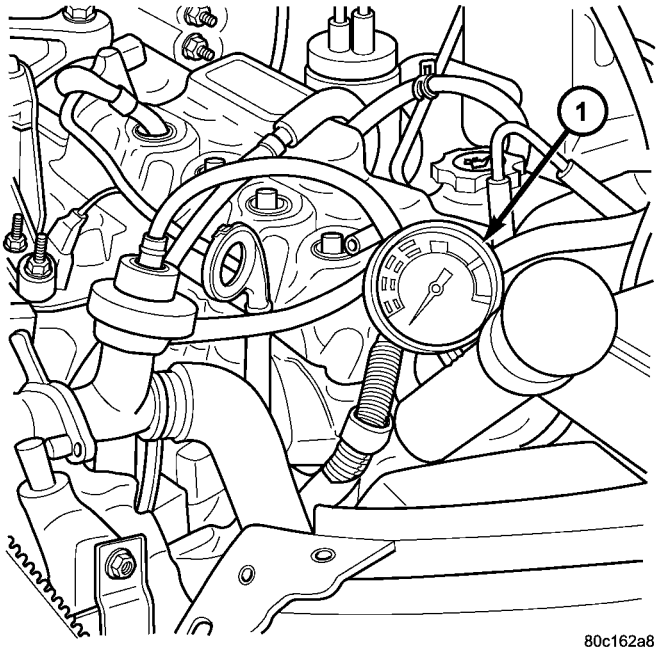

Fig. 2 Pressure Testing Cooling System

1 - PRESSURE TESTER

ENGINE - 1.6L SOHC (Continued)

If there are no external leaks after the gauge dial shows a drop in pressure, detach the tester. Start engine and run the engine to normal operating temperature in order to open the thermostat and allow the coolant to expand. Reattach the tester. If the needle on the dial fluctuates, it indicates a combustion leak and is usually a head gasket leak.

WARNING: WITH TOOL IN PLACE PRESSURE BUILDS UP FAST. ANY EXCESSIVE AMOUNT OF PRESSURE BUILT UP BY CONTINUOUS ENGINE OPERATION MUST BE RELEASED TO A SAFE PRESSURE POINT. NEVER PERMIT PRESSURE TO EXCEED 138 kPa (20 psi).

If the needle on the dial does not fluctuate, race the engine a few times. If an abnormal amount of coolant or steam is emitted from the tailpipe, it may indicate a faulty head gasket, cracked engine block or cylinder head.

There may be internal leaks which can be determined by removing the oil dipstick. If water globules appear intermixed with the oil, it will indicate a internal leak in the engine. If there is an internal leak, the engine must be disassembled for repair.

STANDARD PROCEDURE

STANDARD PROCEDURE - DRAINING COOLING SYSTEM

WARNING: DO NOT OPEN THE RADIATOR DRAINCOCK WITH THE SYSTEM HOT AND UNDER PRESSURE. SERIOUS BURNS FROM COOLANT CAN OCCUR.

NOTE: Drain, flush, and fill the cooling system at the mileage or time intervals specified in the MAINTENANCE SCHEDULE (Refer to LUBRICATION & MAINTENANCE/MAINTENANCE SCHEDULES - DESCRIPTION). If the solution is dirty, rusty, or contains a considerable amount of sediment; clean and flush with a reliable cooling system cleaner. Care should be taken in disposing of the used engine coolant from your vehicle. Check governmental regulations for disposal of used engine coolant.

(1) Position a clean collecting container under draincock location.

(2) Without removing the pressure cap and with system not under pressure, turn draincock counterclockwise to open (Fig. 3).

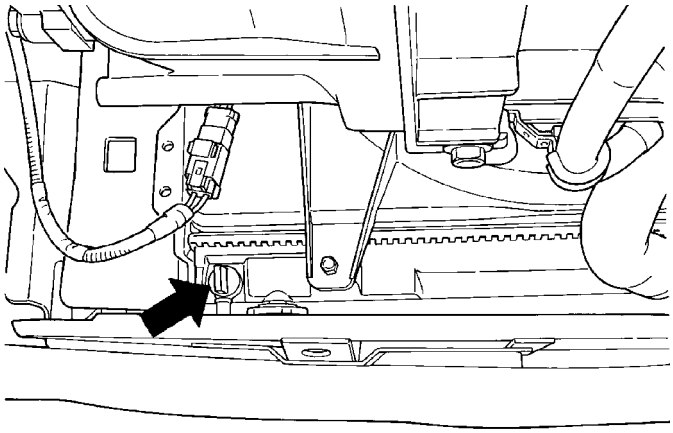
(3) The coolant reserve bottle should empty first, then remove the pressure cap.

(4) If coolant reserve bottle does not empty first:

(a) Check condition of the pressure cap and cap seals.

(b) Check for kinked/torn overflow hose from filler neck to reserve bottle.

(5) Allow cooling system to drain completely.



80c4b6c0

Fig. 3 Cooling System

STANDARD PROCEDURE - FILLING COOLING SYSTEM

WARNING: MAKE SURE ENGINE COOLING SYSTEM IS COOL BEFORE REMOVING PRESSURE CAP OR ANY HOSE. THE COOLING SYSTEM IS PRESSURIZED WHEN HOT. SEVERE PERSONAL INJURY MAY RESULT FROM ESCAPING HOT COOLANT.

CAUTION: Do not use well water, or suspect water supply in cooling system. A 50/50 mixture of the recommended ethylene glycol and distilled water is recommended. For recommended coolant usage, (Refer to LUBRICATION & MAINTENANCE/FLUID TYPES - DESCRIPTION).

NOTE: For cooling system capacity (Refer to LUBRICATION & MAINTENANCE/SPECIFICATIONS - FLUID CAPACITIES).

ENGINE - 1.6L SOHC (Continued)

(1) Close radiator draincock. **Hand tighten only.**

(2) Remove cooling system pressure cap. Install Special Tool 8195 Filling Aid Funnel (Fig. 4).

(3) Use the supplied clip to pinch overflow hose that connects between the radiator and the coolant recovery container (Fig. 4).

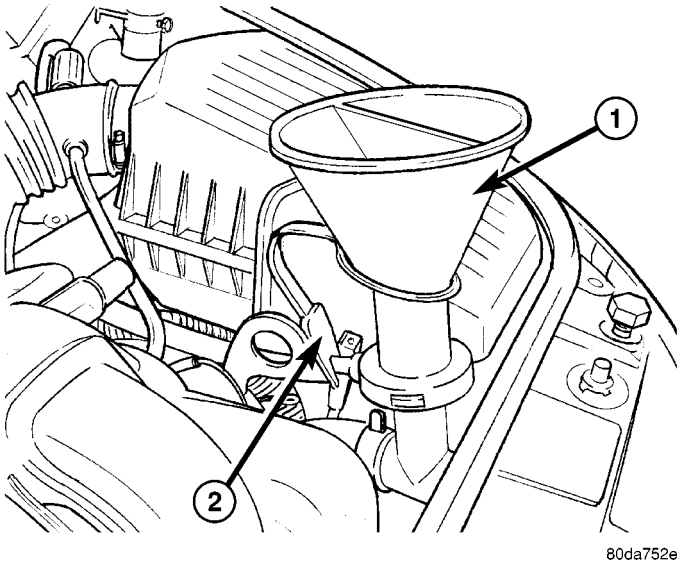


Fig. 4 Filling the Cooling System

1 - SPECIAL TOOL 8195 FILLING AID FUNNEL
2 - PINCH OVERFLOW HOSE

(4) Place a piece of clear 6.35 mm (0.250 in.) I.D. tubing 305 mm (12 in.) long over the cooling system bleed screw nipple. The cooling system bleed screw is located in the heater hose near the coolant recovery container (Fig. 5).

(5) Open, but do not remove, the cooling system bleed screw.

NOTE: While filling the cooling system, pour coolant into the larger section of the Filling Aid Funnel 8195.

(6) Slowly fill the cooling system until a small column of coolant begins to fill the clear plastic tube on the bleed screw.

(7) Close the cooling system bleed screw and remove the tubing.

(8) Remove clip from overflow hose and remove funnel 8195.

(9) Install cooling system pressure cap.

(10) Slowly fill the coolant recovery container to the FULL HOT mark with the recommended coolant. It may be necessary to add coolant to the recovery container after one warm-up/cool down cycle in order to maintain the coolant level between the FULL HOT and ADD marks. This is due to the removal of trapped air from the system.

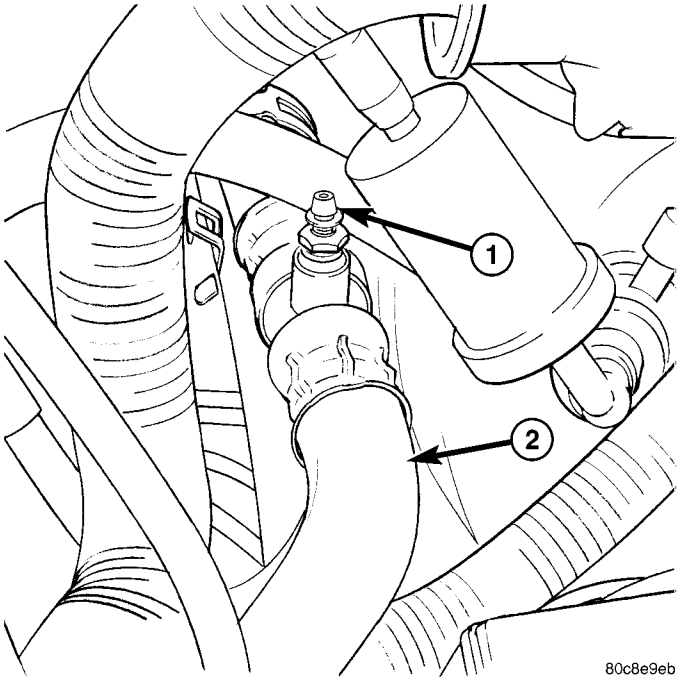

Fig. 5 Cooling System Bleed Screw

1 - COOLING SYSTEM BLEED SCREW
2 - HEATER HOSE

CLEANING

CAUTION: Internal radiator pressure must not exceed 138 kPa (20 psi) as damage to radiator may result.

Reverse flushing of cooling system is the forcing of water through the cooling system. This is done using air pressure in the opposite direction of normal coolant flow. It is usually only necessary with very dirty systems with evidence of partial plugging.

(1) Drain cooling system. Remove thermostat housing and thermostat. Install thermostat housing.

(2) Connect a suitable cooling system flusher and follow instructions supplied with flusher.

INSPECTION

After performing a cleaning/flush procedure, inspect all hoses, clamps and connections for deterioration and leaks. Inspect radiator and heater core for leaks.

COOLANT

DESCRIPTION

CAUTION: Use of Propylene Glycol based coolants is not recommended, as they provide less freeze protection and less corrosion protection. Do not mix coolant types. If coolant other than Mopar® Antifreeze/Coolant, 5 Year/100,000 Mile Formula or equivalent is added, the mixed coolant will have a reduced service schedule.

The use of aluminum cylinder heads, and water pumps requires special corrosion protection. Mopar® Antifreeze/Coolant, 5 Year/100,000 Mile Formula or equivalent ethylene glycol based coolant with corrosion inhibitors (called HOAT, for Hybrid Organic Additive Technology) is recommended. This coolant offers the best engine cooling without corrosion when mixed with 50% Ethylene Glycol and 50% distilled water to obtain a freeze point of -37°C (-35°F). If it loses color or becomes contaminated, drain, flush, and replace with fresh properly mixed coolant solution. Mixing of coolants other than specified (non-HOAT), will reduce the 5 year/100,000 mile corrosion protection.

DIAGNOSIS AND TESTING - COOLANT CONCENTRATION TESTING

Coolant concentration should be checked when any additional coolant was added to system or after a coolant drain, flush and refill. The coolant mixture offers optimum engine cooling and protection against corrosion when mixed to a freeze point of -37°C (-34°F) to -46°C (-50°F). The use of a hydrometer or a refractometer can be used to test coolant concentration.

A hydrometer will test the amount of glycol in a mixture by measuring the specific gravity of the mixture. The higher the concentration of ethylene glycol, the larger the number of balls that will float, and higher the freeze protection (up to a maximum of 60% by volume glycol).

A refractometer (Special Tool 8286)(Refer to 7 - COOLING - SPECIAL TOOLS) will test the amount of glycol in a coolant mixture by measuring the amount a beam of light bends as it passes through the fluid.

Some coolant manufactures use other types of glycols into their coolant formulations. Propylene glycol is the most common new coolant. However, propylene glycol based coolants do not provide the same freezing protection and corrosion protection and is not recommended.

CAUTION: Do not mix types of coolant—corrosion protection will be severely reduced.

STANDARD PROCEDURE

STANDARD PROCEDURE - COOLANT SERVICE

For engine coolant recommended service schedule, (Refer to LUBRICATION & MAINTENANCE/MAINTENANCE SCHEDULES - DESCRIPTION).

STANDARD PROCEDURE - ROUTINE COOLANT LEVEL CHECK

NOTE: Do not remove pressure cap for routine coolant level inspections.

The coolant recovery/reserve system provides a quick visual method for determining the coolant level without removing the radiator cap. Simply observe, with the engine idling and warmed up to normal operating temperature, that the level of the coolant in the recovery/reserve container is between the FULL HOT and ADD marks (Fig. 6).

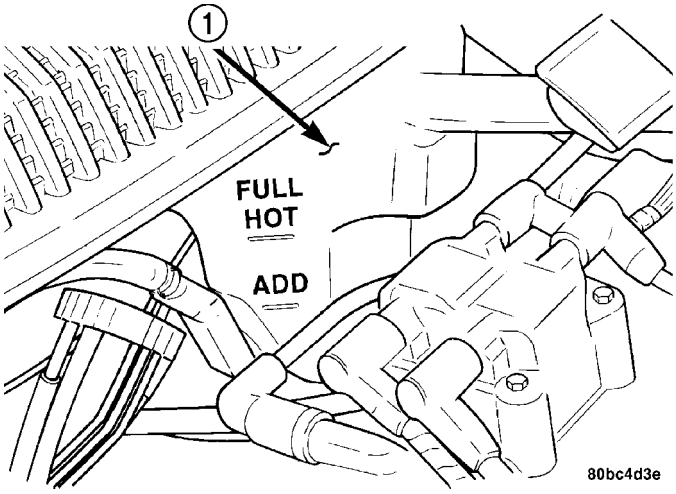

Fig. 6 Coolant Level

1 - COOLANT RECOVERY CONTAINER

COOLANT (Continued)

STANDARD PROCEDURE - ADDING ADDITIONAL COOLANT

NOTE: The radiator cap should not be removed.

NOTE: If the cooling system is completely empty, (Refer to 7 - COOLING/ENGINE - STANDARD PROCEDURE - FILLING COOLING SYSTEM).

When additional coolant is needed, it should be added to the coolant recovery container. Use only a 50/50 concentration of the recommended ethylene glycol type antifreeze and distilled water. (Refer to LUBRICATION & MAINTENANCE/FLUID TYPES - DESCRIPTION).

HOSE CLAMPS

DESCRIPTION - HOSE CLAMPS

The cooling system uses spring type hose clamps. If a spring type clamp replacement is necessary, replace with the original Mopar® equipment spring type clamp.

CAUTION: A number or letter is stamped into the tongue of constant tension clamps. If replacement is necessary, use only a original equipment clamp with matching number or letter (Fig. 7).

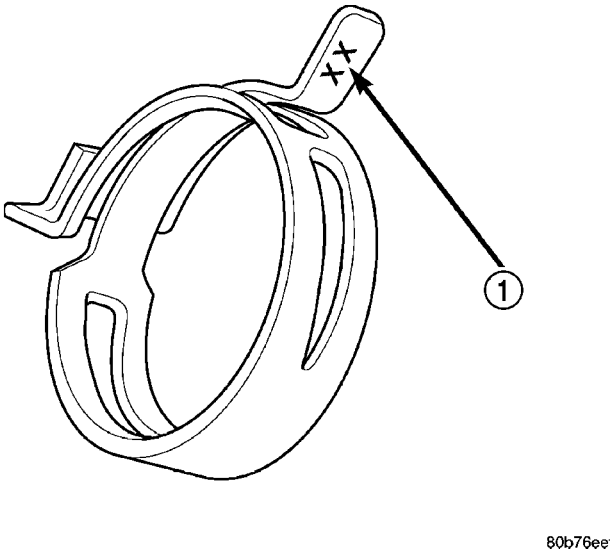

Fig. 7 Spring Clamp Size Location

1 - SPRING CLAMP SIZE LOCATION

The spring type hose clamp applies constant tension on a hose connection. To remove a spring type hose clamp, use Special Tool 6094 or 8495 (or equivalent), constant tension clamp pliers (Fig. 8) to compress the hose clamp.

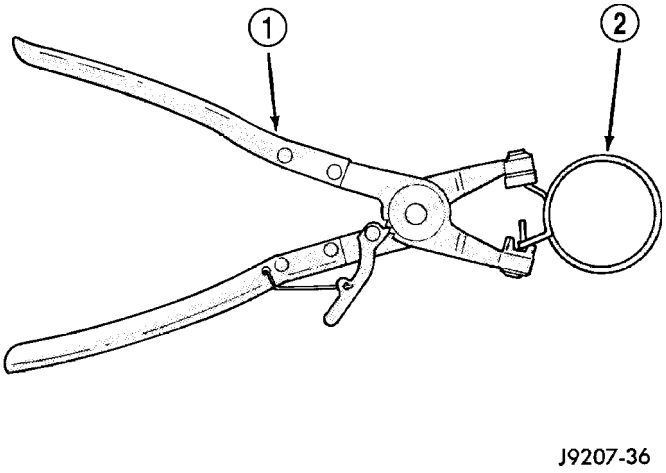

Fig. 8 Hose Clamp Tool

1 - HOSE CLAMP TOOL 6094
2 - HOSE CLAMP

COOLANT RECOVERY CONTAINER

DESCRIPTION

The coolant recovery system consists of a coolant recovery container mounted to the dash panel, a vent hose for the coolant recovery container, a hose connecting the container to the radiator neck, and a pressure cap (Fig. 9) and (Fig. 10).

OPERATION

The system works in conjunction with the cooling system pressure cap to utilize thermal expansion and contraction of the coolant to keep the coolant free of trapped air. The system provides space for expansion and contraction. Also, the system provides a convenient and safe method for checking and adjusting the coolant level at atmospheric pressure without removing the pressure cap. It also provides some reserve coolant to compensate for minor leaks and evaporation or boiling losses.

COOLANT RECOVERY CONTAINER (Continued)

REMOVAL

(1) Siphon coolant from coolant recovery container.
(2) Remove vent hose clip from stud on dash panel (Fig. 9).
(3) Disconnect overflow hose at radiator neck (Fig. 10).
(4) Remove container attaching fasteners (Fig. 9).
(5) Remove coolant recovery container.

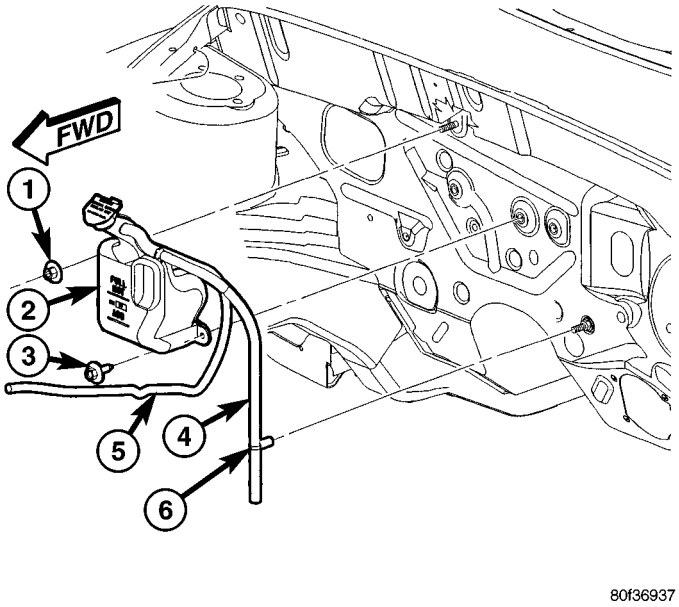

Fig. 9 Coolant Recovery Container

1 - NUT
2 - COOLANT RECOVERY CONTAINER
3 - SCREW
4 - VENT HOSE
5 - OVERFLOW HOSE
6 - CLIP

INSTALLATION

(1) Install coolant recovery container and tighten fasteners to 4 N·m (35 in. lbs.) (Fig. 9).
(2) To ensure proper vent hose routing, install vent hose clip on stud at dash panel (Fig. 9).
(3) Connect overflow hose at radiator neck (Fig. 10).
(4) Fill coolant recovery container to proper level.

ENGINE BLOCK HEATER

DESCRIPTION

The heater is mounted in a core hole (in place of a core hole plug) in the engine block near the starter mounting location. The heating element immersed in coolant (Fig. 11). The engine block heater is available as an optional accessory. The heater is operated by

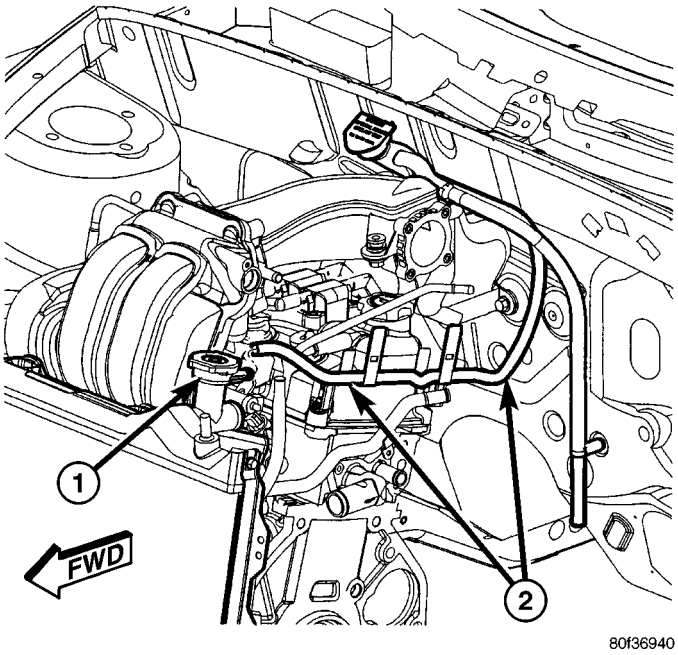

Fig. 10 Overflow Hose Routing

1 - RADIATOR NECK
2 - OVERFLOW HOSE

ordinary house current (110 Volt A.C.) through a power cord and connector behind the radiator grille.

CAUTION: The power cord must be secured in its retainer clips, and not positioned so it could contact linkages or exhaust manifolds and become damaged.

OPERATION

The block heater element is submerged in the cooling system's coolant. When electrical power (110 volt A.C.) is applied to the element, it creates heat. This heat is transferred to the engine coolant. This provides easier engine starting and faster warm-up when vehicle is operated in areas having extremely low temperatures.

DIAGNOSIS AND TESTING - ENGINE BLOCK HEATER TESTING

If unit does not operate, trouble can be in either the power cord or the heater element. Test power cord for continuity with a 110-volt voltmeter or 110-volt test light; test heater element continuity with an ohmmeter or 12-volt test light.

REMOVAL

(1) Drain the cooling system (Refer to 7 - COOLING/ENGINE - STANDARD PROCEDURE).
(2) Raise vehicle on hoist.

ENGINE BLOCK HEATER (Continued)

(3) Detach power cord plug from heater.

(4) Loosen screw in center of heater. Remove heater assembly (Fig. 11).

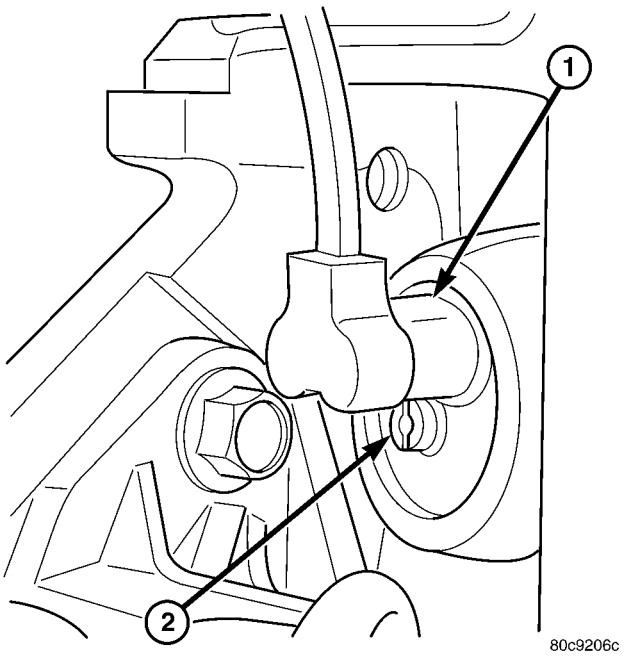

Fig. 11 Engine Block Heater

1 - BLOCK HEATER
2 - SCREW

INSTALLATION

(1) Thoroughly clean core hole and heater seat.

(2) Insert heater assembly with element loop positioned **upward (Fig. 11)**.

(3) With heater seated, tighten center screw securely to assure a positive seal.

(4) Connect power cord to block heater.

(5) Lower vehicle.

(6) Fill the cooling system (Refer to 7 - COOLING/ENGINE - STANDARD PROCEDURE).

ENGINE COOLANT TEMP SENSOR

DESCRIPTION

The engine coolant temperature (ECT) sensor threads into the rear of the cylinder head, below the thermostat housing (Fig. 12). New sensors have sealant applied to the threads. The ECT Sensor is a Negative Thermal Coefficient (NTC) sensor.

OPERATION

The ECT sensor provides an input to the PCM. As temperature increases, resistance of the sensor decreases. As coolant temperature varies, the ECT sensor resistance changes resulting in a different voltage value at the PCM ECT sensor signal circuit. The ECT sensor provides input for various PCM operations. The PCM uses the input to control air-fuel mixture, timing, and radiator fan on/off times. The ECT sensor input is also used for temperature gauge operation.

REMOVAL

(1) Disconnect negative battery cable.

(2) Disconnect positive battery cable.

(3) Remove battery.

(4) Partially drain cooling system.

(5) Disconnect coolant temperature sensor electrical connector.

(6) Remove coolant temperature sensor (Fig. 12).

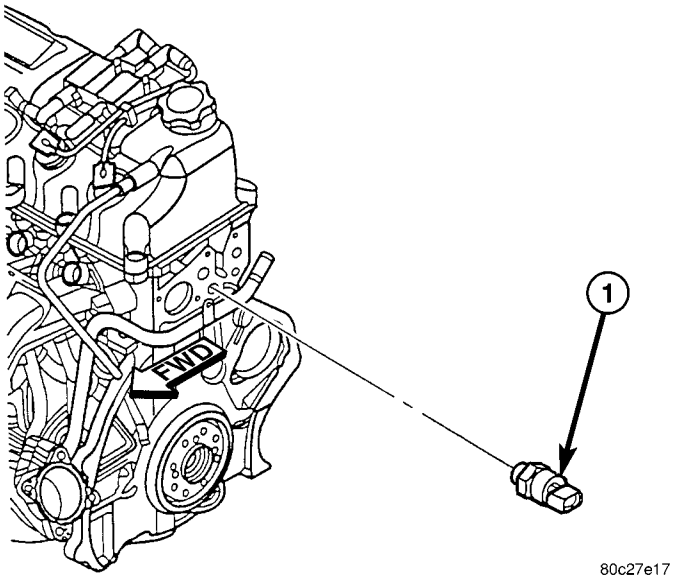

Fig. 12 Engine Coolant Temperature Sensor

1 - ENGINE COOLANT TEMPERATURE SENSOR

INSTALLATION

(1) Install coolant temperature sensor (Fig. 12). Tighten sensor to 17 N·m (150 in. lbs.).

(2) Reconnect coolant temperature sensor connector.

(3) Install battery.

(4) Connect positive battery cable.

(5) Connect negative battery cable.

(6) Fill cooling system (Refer to 7 - COOLING/ENGINE - STANDARD PROCEDURE).

ENGINE COOLANT THERMOSTAT AND HOUSING

REMOVAL

(1) Disconnect negative battery cable.
(2) Disconnect positive battery cable.
(3) Remove battery.
(4) Partially drain cooling system.
(5) Remove fasteners securing heater return tube to engine block and thermostat housing. Reposition heater tube.
(6) Disconnect upper radiator hose and heater hose from thermostat housing.
(7) Remove thermostat housing fasteners (Fig. 13).

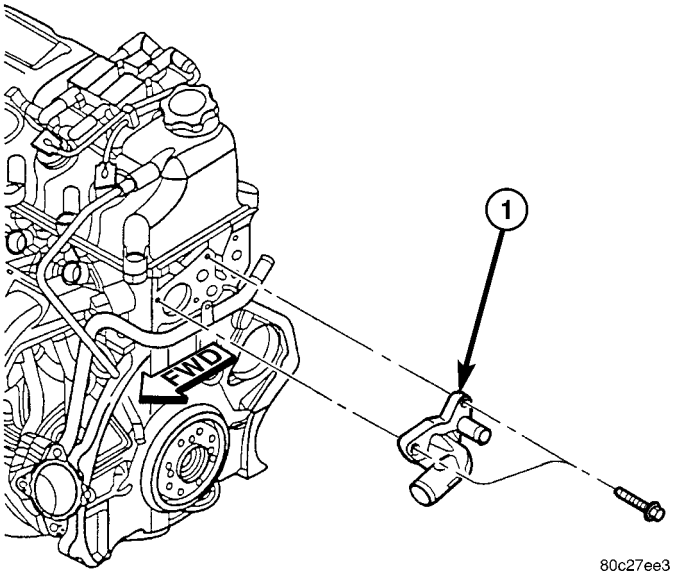

Fig. 13 Engine Coolant Thermostat Housing

1 - ENGINE COOLANT THERMOSTAT HOUSING

INSTALLATION

(1) Clean all sealing surfaces.
(2) Place thermostat and seal into thermostat housing. Align air bleed with notch in thermostat housing (Fig. 14).
(3) Install thermostat housing and fasteners. Torque fasteners to 7 N·m (65 in. lbs.) (Fig. 13).
(4) Connect upper radiator hose and heater hose to thermostat housing.
(5) Install fasteners securing heater return tube to engine block and thermostat housing.
(6) Install battery.
(7) Connect positive battery cable.
(8) Connect negative battery cable.
(9) Fill cooling system (Refer to 7 - COOLING/ENGINE - STANDARD PROCEDURE).

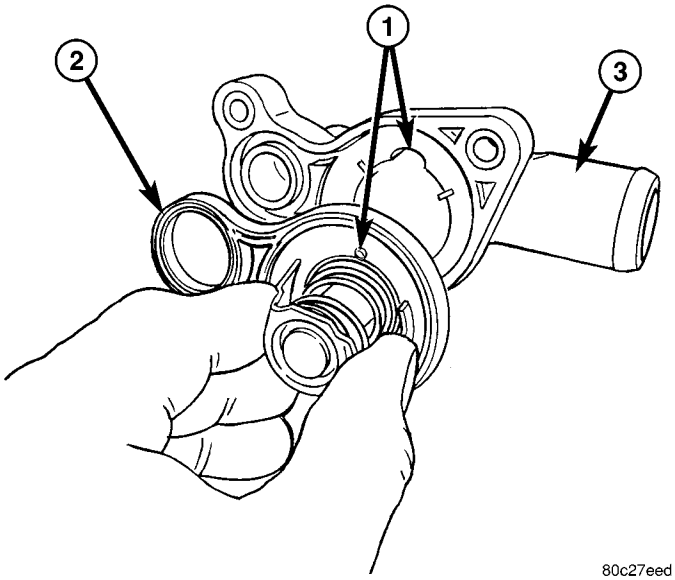

Fig. 14 Thermostat Orientation

1 - ALIGN AIR BLEED WITH NOTCH IN THERMOSTAT HOUSING
2 - THERMOSTAT SEAL
3 - THERMOSTAT HOUSING

RADIATOR PRESSURE CAP

DESCRIPTION

The cooling system is equipped with a pressure cap that releases built up pressure, maintaining a range of 97-124 kPa (14-18 psi).

There is also a vent valve in the center of the cap. This valve also opens when coolant is cooling and contracting, allowing coolant to return to radiator from coolant recovery container by vacuum through connecting hose. **If valve is stuck shut, the radiator hoses will be collapsed on cool down. Clean the vent valve (Fig. 15) to ensure proper sealing when boiling point is reached.**

OPERATION

The pressure cap allows the cooling system to operate at higher than atmospheric pressure. The higher pressure raises the coolant boiling point; this allows increased radiator cooling capacity.

The gasket in the cap seals the filler neck, so that vacuum can be maintained, allowing coolant to be drawn back into the radiator from the reserve container.

DIAGNOSIS AND TESTING

DIAGNOSIS AND TESTING - COOLING SYSTEM PRESSURE CAP TESTING

Dip the pressure cap in water. Clean any deposits off the vent valve or its seat and apply cap to end of

RADIATOR PRESSURE CAP (Continued)

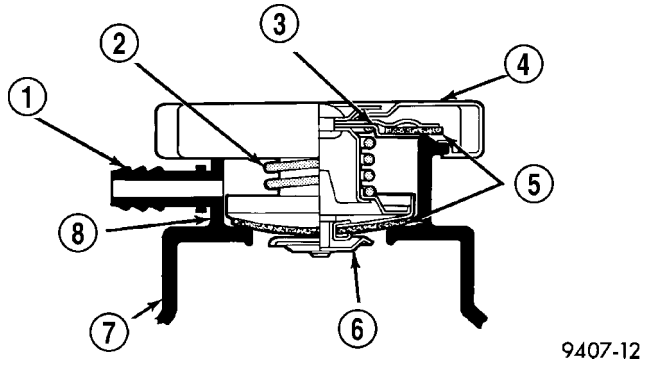

Fig. 15 Cooling System Pressure Cap

1 - OVERFLOW NIPPLE
2 - MAIN SPRING
3 - GASKET RETAINER
4 - STAINLESS-STEEL SWIVEL TOP
5 - RUBBER SEALS
6 - VENT VALVE
7 - RADIATOR
8 - FILLER NECK

the Pressure Cap Test Adaptor that is included with the Cooling System Tester 7700. Working the plunger, bring the pressure to 104 kPa (15 psi) on the gauge. If the pressure cap fails to hold pressure of at least 97 kPa (14 psi), replace the pressure cap.

CAUTION: The Cooling System Tester Tool is very sensitive to small air leaks that will not cause cooling system problems. A pressure cap that does not have a history of coolant loss should not be replaced just because it leaks slowly when tested with this tool. Add water to the tool. Turn tool upside down and recheck pressure cap to confirm that cap is bad.

If the pressure cap tests properly while positioned on Cooling System Tester (Fig. 16), but will not hold pressure or vacuum when positioned on the filler neck. Inspect the filler neck and cap top gasket for irregularities that may prevent the cap from sealing properly.

DIAGNOSIS AND TESTING - COOLING SYSTEM PRESSURE RELIEF TESTING

WARNING: IF VEHICLE HAS BEEN RUN RECENTLY, WAIT 15 MINUTES BEFORE REMOVING CAP. PLACE A SHOP TOWEL OVER THE CAP, AND WITHOUT PUSHING DOWN, ROTATE IT COUNTERCLOCKWISE TO THE FIRST STOP. ALLOW FLUIDS TO ESCAPE THROUGH THE OVERFLOW TUBE. WHEN THE SYSTEM STOPS PUSHING COOLANT AND STEAM INTO THE COOLANT RECOVERY CONTAINER AND PRESSURE DROPS, PUSH DOWN ON THE CAP AND REMOVE IT COMPLETELY. SQUEEZING THE RADIATOR INLET HOSE WITH A SHOP TOWEL (TO CHECK PRESSURE) BEFORE AND AFTER TURNING TO THE FIRST STOP IS RECOMMENDED.

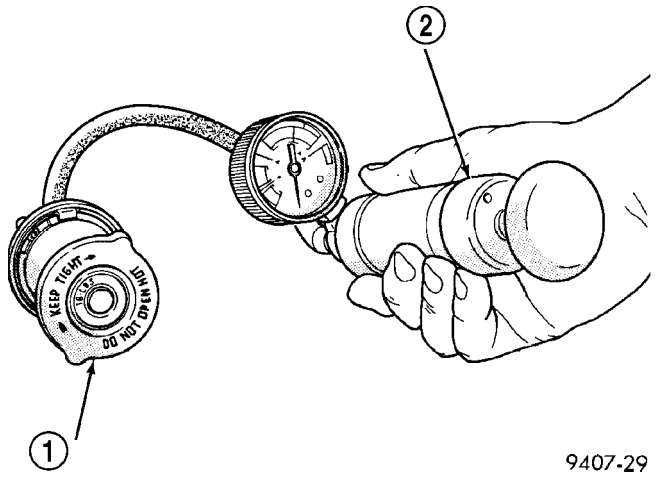

Fig. 16 Pressure Testing Radiator Cap

1 - PRESSURE CAP
2 - PRESSURE TESTER

WARNING: THE WARNING WORDS “DO NOT OPEN HOT” ON THE PRESSURE CAP IS A SAFETY PRECAUTION. WHEN HOT, THE COOLING SYSTEM BUILDS UP PRESSURE. TO PREVENT SCALDING OR OTHER INJURY, THE PRESSURE CAP SHOULD NOT BE REMOVED WHILE THE SYSTEM IS HOT AND/OR UNDER PRESSURE.

The pressure cap upper gasket to filler neck seal can be checked by removing the overflow hose at the radiator filler neck overflow nipple (Fig. 15). Attach the radiator pressure tester to the **filler neck overflow nipple,** and pump air into the system. The pressure cap upper gasket should relieve pressure at 69-124 kPa (10-18 psi), and hold pressure at 55 kPa (8 psi) minimum.

There is no need to remove the pressure cap at any time **except** for the following purposes:

- Check and adjust coolant freeze point
- Refill system with new coolant
- Conducting service procedures
- Checking for leaks

CLEANING

Use only a mild soap to clean the pressure cap.

INSPECTION

Hold the cap in your hand, **top side up** (Fig. 15). The vent valve at the bottom of the cap should open. If the rubber gasket has swollen, preventing the valve from opening, replace the cap.

Hold the cleaned cap in your hand, **upside down.** If any light can be seen between vent valve and the

RADIATOR PRESSURE CAP (Continued)

rubber gasket, replace the cap. **Do not use a replacement cap that has a spring to hold the vent shut.**

A replacement cap must be of the type designed for coolant reserve systems. This design ensures coolant return to the radiator.

RADIATOR DRAINCOCK

REMOVAL

CAUTION: Use of pliers on draincock is not recommended. Damage may occur to radiator or draincock.

NOTE: It is not necessary to remove draincock during a routine coolant drain.

(1) Drain the cooling system (Refer to 7 - COOLING/ENGINE - STANDARD PROCEDURE).

(2) Open the draincock by turning it counterclockwise until it stops.

(3) Turn the draincock back (clockwise) 1/8 turn.

(4) Pull the draincock (Fig. 17) from the radiator tank.

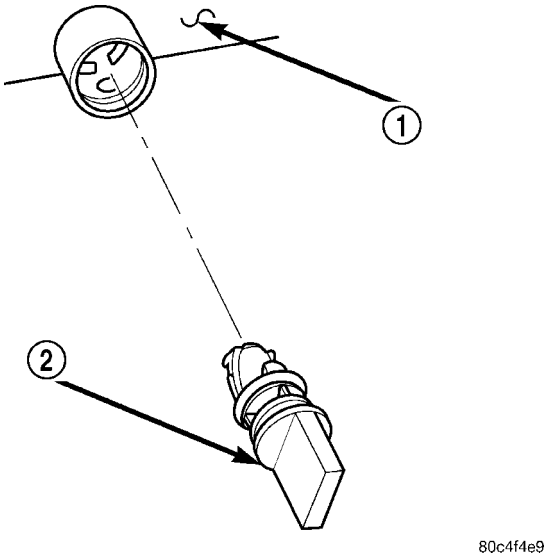

Fig. 17 Draincock

1 - RADIATOR TANK
2 - DRAINCOCK

INSTALLATION

(1) Align draincock stem to radiator tank opening.

(2) Push draincock into the radiator tank opening.

(3) Tighten the draincock by turning clockwise until it stops.

(4) Fill the cooling system (Refer to 7 - COOLING/ENGINE - STANDARD PROCEDURE).

RADIATOR FAN

DESCRIPTION

The radiator cooling fan is a dual-speed electric motor driven fan. The radiator fan assembly includes an electric motor, fan blade, and a support shroud that is attached to the radiator (Fig. 18). The radiator fan is serviced as an assembly.

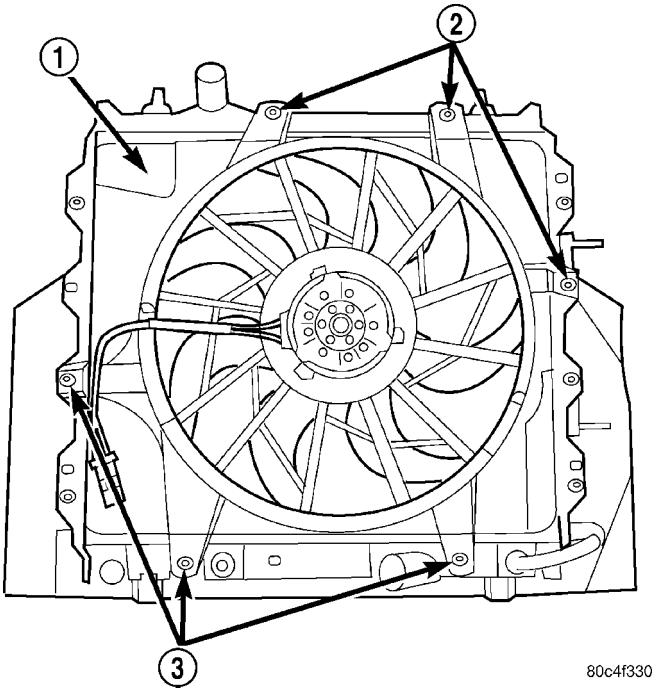

Fig. 18 Radiator Fan

1 - RADIATOR FAN SHROUD
2 - SCREWS
3 - SCREWS

OPERATION

Radiator fan operation is control by the Powertrain Control Module (PCM) with inputs from the temperature of the coolant, which is sensed by the coolant temperature sensor, and vehicle speed which is measured by the vehicle speed sensor. The PCM turns on the fan through either the high or low speed fan relay. The PCM provides a ground to the relay's control circuit. The fan relays are located in the Power Distribution Center (PDC) (Fig. 19). Refer to the label beneath the PDC cover for location of fan relays.

RADIATOR FAN (Continued)

Refer to **Radiator Fan Operation Chart** for fan operation specifications. For fan circuit wiring diagrams, refer to WIRING DIAGRAMS.

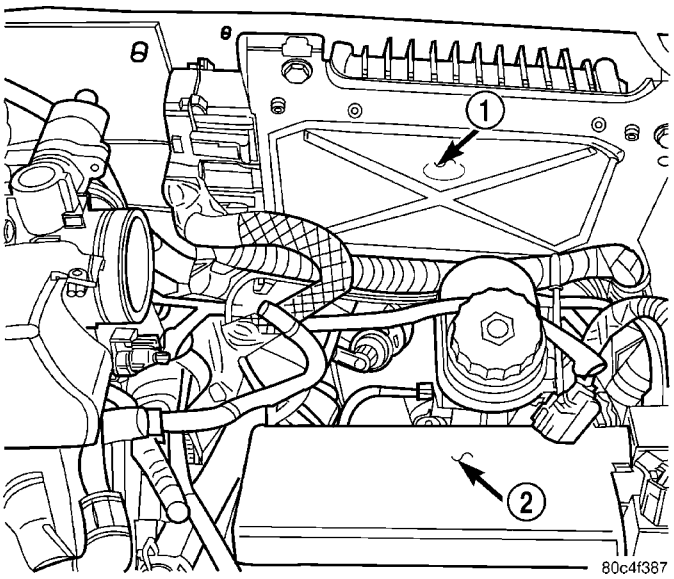

Fig. 19 Power Distribution Center (PDC)

1 - PCM
2 - PDC

If the cooling fan is inoperative or a Diagnostic Trouble Code (DTC) related to fan control has been set, refer to the appropriate Powertrain Diagnostic Information for diagnostic procedures.

RADIATOR FAN OPERATION CHART

Radiator Fan Control		
	Low Speed	**High Speed**
A/C Off –vehicle speed < 70.8 km/h (44 mph)		
Fan On:	96.6° C (206° F)	103° C (219° F)
Fan Off:	92.7° C (199° F)	98.8° C (210° F)
A/C Off –vehicle speed > 70.8 km/h (44 mph) (until vehicle speed drops below 58 km/h (36 mph)		
Fan On:	Off	103° C (219° F)
Fan Off:		98.8° C (210° F)
A/C On –any vehicle speed		
Fan On:	Off	82.2° C (180° F)
Fan Off:		80° C (176° F)

DIAGNOSIS AND TESTING - RADIATOR FAN

(Refer to Appropriate Diagnostic Information)

REMOVAL

NOTE: The fan motor, fan, and the shroud are serviced as an assembly.

WARNING: DO NOT REMOVE THE CYLINDER BLOCK PLUG OR THE RADIATOR DRAINCOCK WITH THE SYSTEM HOT AND UNDER PRESSURE BECAUSE SERIOUS BURNS FROM COOLANT CAN OCCUR.

(1) Disconnect negative cable from battery.
(2) Partially drain cooling system below upper radiator hose level (Refer to 7 - COOLING/ENGINE - STANDARD PROCEDURE).
(3) Remove grille (Refer to 23 - BODY/EXTERIOR/ GRILLE - REMOVAL).
(4) Remove upper radiator closure panel (Refer to 23 - BODY/EXTERIOR/RADIATOR CLOSURE PANEL - REMOVAL) (Fig. 20).

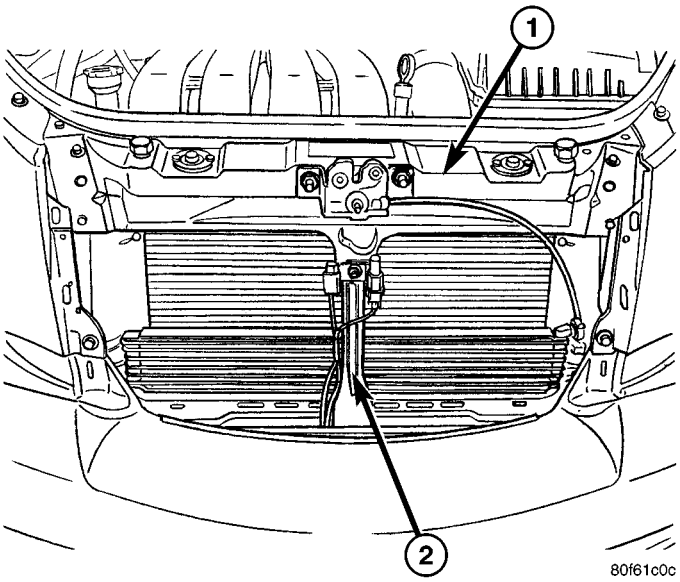

Fig. 20 Upper Radiator Closure Panel and Center Brace

1 - UPPER RADIATOR CLOSURE PANEL
2 - CENTER BRACE

(5) Disconnect upper radiator hose and overflow hose from radiator filler neck (Fig. 21).
(6) Remove radiator filler neck (Fig. 21).
(7) Raise vehicle on hoist.
(8) Disconnect radiator fan electrical connector.
(9) Remove the two lower and left side radiator fan screws (Fig. 18).

RADIATOR FAN (Continued)

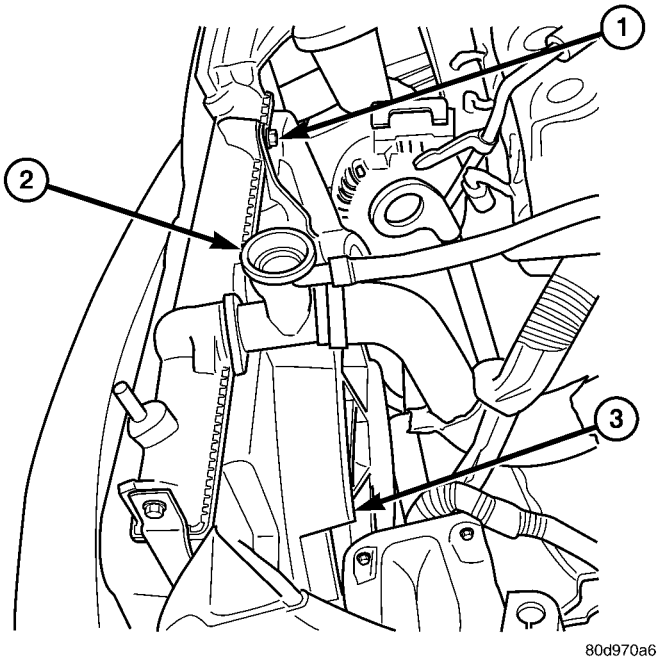

Fig. 21 Radiator Filler Neck

1 - FAN MOUNTING NUT
2 - RADIATOR FILLER NECK
3 - FAN

(10) Lower vehicle and remove the remaining radiator fan attaching screws (Fig. 18).

CAUTION: Care should be taken not to damage the radiator cooling fins and tubes during fan removal.

(11) Remove radiator fan by lifting up from the engine compartment.

INSTALLATION

(1) Install the radiator fan into position on the radiator.

(2) Install the upper and right side radiator fan retaining screws and tighten to 6 N·m (55 in. lbs.) (Fig. 18).

(3) Raise vehicle and install the remaining fan attaching screws. Tighten to 6 N·m (55 in. lbs.) (Fig. 18).

(4) Connect radiator fan electrical connector.

(5) Lower vehicle.

(6) Install radiator filler neck to radiator. Connect upper radiator hose and overflow hose to radiator filler neck (Fig. 21).

(7) Install upper radiator closure panel (Refer to 23 - BODY/EXTERIOR/RADIATOR CLOSURE PANEL - INSTALLATION) (Fig. 20).

(8) Install grille (Refer to 23 - BODY/EXTERIOR/GRILLE - INSTALLATION).

(9) Connect negative battery cable.

(10) Fill the cooling system (Refer to 7 - COOLING/ENGINE - STANDARD PROCEDURE).

RADIATOR

REMOVAL

WARNING: DO NOT REMOVE THE CYLINDER BLOCK PLUG OR THE RADIATOR DRAINCOCK WITH THE SYSTEM HOT AND UNDER PRESSURE BECAUSE SERIOUS BURNS FROM COOLANT CAN OCCUR.

NOTE: It is not necessary to discharge the air conditioning system to remove the radiator.

(1) Disconnect negative cable from battery.

(2) Raise vehicle on hoist.

(3) Drain the cooling system (Refer to 7 - COOLING/ENGINE - STANDARD PROCEDURE).

(4) Disconnect radiator fan motor electrical connector (Fig. 22).

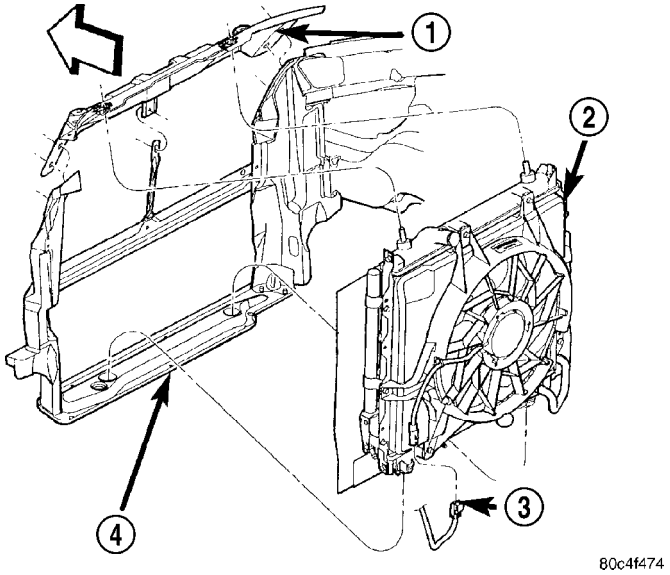

Fig. 22 Cooling Module

1 - UPPER RADIATOR CROSSMEMBER

(8) Lower vehicle.

(9) Remove grille (Refer to 23 - BODY/EXTERIOR/GRILLE - REMOVAL).

(10) Remove upper radiator closure panel (Refer to 23 - BODY/EXTERIOR/RADIATOR CLOSURE PANEL - REMOVAL).

(11) Disconnect upper radiator hose and overflow hose from the radiator filler neck (Fig. 25).

(12) Remove remaining fasteners attaching radiator fan shroud to radiator (Fig. 23).

(13) Remove radiator fan/shroud assembly.

(14) Remove remaining fasteners attaching AC condenser to radiator. Reposition AC condenser.

(15) Remove radiator assembly by lifting it up from the engine compartment. **Care should be taken not to damage the cooling fins and tubes during removal.**

(16) Remove the lower air seal from radiator (Fig. 24).

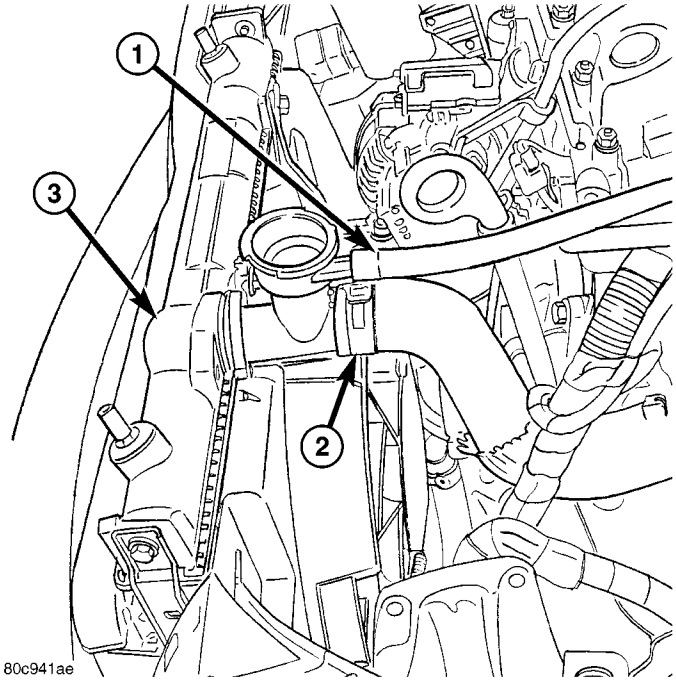

Fig. 25 Radiator

1 - OVERFLOW HOSE
2 - UPPER RADIATOR HOSE
3 - RADIATOR ASSEMBLY

CLEANING

Clean radiator fins are necessary for good heat transfer. The radiator and air conditioning fins should be cleaned when an accumulation of debris has occurred. With the engine cold, apply cold water and compressed air to the back (engine side) of the radiator to flush the radiator and/or A/C condenser of debris.

RADIATOR (Continued)

INSPECTION

Inspect the radiator tanks for cracks, broken or missing fittings also inspect the joint where the tanks seam up to the radiator core for signs of leakage and/or deteriorating seals.

Inspect radiator core for corroded, bent or missing cooling fins. Inspect the core for bent or damaged cooling tubes.

INSTALLATION

(1) Install the lower air seal to radiator (Fig. 24).
(2) Position radiator into mounting position.
(3) Position A/C condenser against radiator. Hand start lower fasteners.
(4) Install radiator fan/shroud assembly. Hand start upper fasteners and remaining side fasteners that hold AC condenser also.
(5) Raise vehicle on hoist.
(6) Connect the lower air seal to the side air seals (Fig. 24).
(7) Install two remaining lower radiator fan shroud fasteners to radiator (Fig. 23). Torque fasteners to 6 N·m (55 in. lbs.).
(8) Connect lower radiator hose. Align the hose and position the clamp so it will not interfere with engine components.
(9) Connect the radiator fan motor electrical connector (Fig. 22).
(10) Close radiator draincock.
(11) Lower vehicle.
(12) Torque radiator fan shroud fasteners to 6 N·m (55 in. lbs.).
(13) Torque AC condenser fasteners to 8 N·m (70 in. lbs.).
(14) Connect upper radiator hose and overflow hose (Fig. 25). Align the upper radiator hose and position the clamp to prevent interference with the engine or hood.
(15) Install upper radiator closure panel (Refer to 23 - BODY/EXTERIOR/RADIATOR CLOSURE PANEL - INSTALLATION).
(16) Install grille (Refer to 23 - BODY/EXTERIOR/GRILLE - INSTALLATION).
(17) Connect negative battery cable.
(18) Fill cooling system with coolant (Refer to 7 - COOLING/ENGINE - STANDARD PROCEDURE).
(19) Operate engine until it reaches normal operating temperature. Check cooling system for correct fluid level and leaks.

HEATER RETURN TUBE

REMOVAL

(1) Disconnect negative battery cable.
(2) Disconnect positive battery cable.
(3) Remove battery.
(4) Drain cooling system (Refer to 7 - COOLING/ENGINE - STANDARD PROCEDURE).
(5) Remove fasteners securing heater return tube to engine block and thermostat housing (Fig. 26).
(6) Raise vehicle on hoist.
(7) Remove clamp and disconnect heater hose from water pump.
(8) Lower vehicle.
(9) Remove clamp and disconnect heater hose from heater tube.
(10) Remove heater tube.

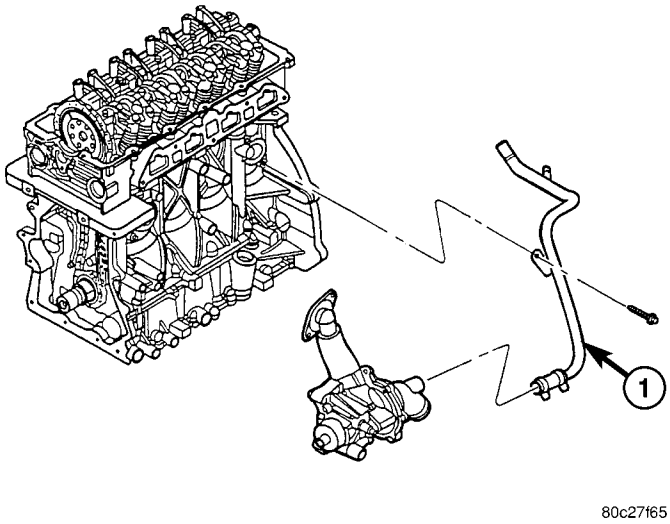

Fig. 26 Heater Return Tube

1- HEATER RETURN TUBE

INSTALLATION

(1) Position heater tube in it's mounting position (Fig. 26).
(2) Connect heater hose to tube. Install clamp.
(3) Raise vehicle on hoist.
(4) Connect heater hose to water pump. Install clamp.
(5) Lower vehicle.
(6) Install fasteners securing heater return tube to engine block and thermostat housing.
(7) Install battery.
(8) Connect positive battery cable.
(9) Connect negative battery cable.
(10) Fill cooling system (Refer to 7 - COOLING/ENGINE - STANDARD PROCEDURE).

WATER PUMP/POWER STEERING PUMP ASSEMBLY

DESCRIPTION

The water pump on this vehicle is attached to the rear of the power steering pump to form an assembly (Fig. 27). The water pump/power steering pump assembly is located on the front corner of the engine (Fig. 29).

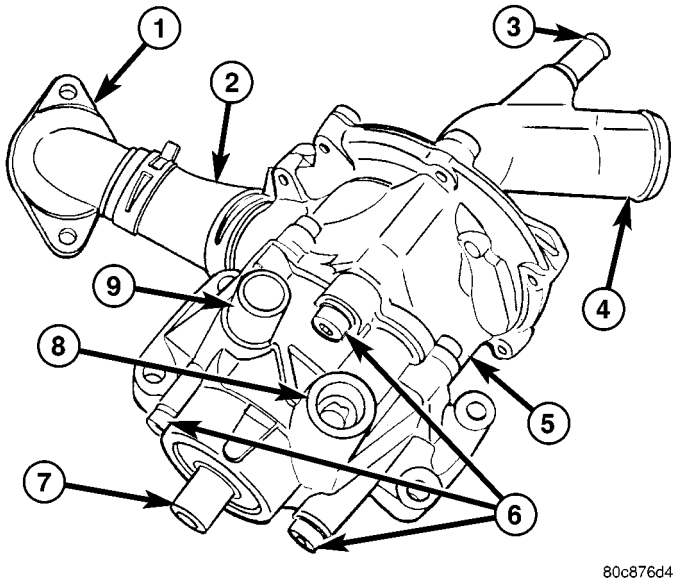

Fig. 27 Water Pump/Power Steering Pump Assembly

1 - CONNECTOR
2 - COOLANT OUTLET CONNECTOR HOSE
3 - HEATER RETURN HOSE INLET
4 - COOLANT INLET
5 - WATER PUMP
6 - PUMP-TO-PUMP ATTACHING (HEX) BOLTS
7 - POWER STEERING PUMP
8 - POWER STEERING PUMP PRESSURE (OUTLET) PORT
9 - POWER STEERING PUMP SUPPLY (INLET) FITTING

The water pump is bolted to the rear of the power steering pump. Driven by the power steering pump shaft, the water pump's impeller is located inside a die-cast aluminum housing. The water pump housing has a built in outlet. The water pump also has a bolt-on inlet cover with two ports, one for incoming coolant from the radiator and the other for incoming coolant from the heater.

Both pumps (water and power steering) can be serviced separately. Remove the entire water pump/power steering pump assembly, then disassemble it to service either pump.

For information on the power steering pump, (Refer to 19 - STEERING/PUMP - DESCRIPTION).

REMOVAL

NOTE: Before proceeding, review all Warnings and Cautions (Refer to 7 - COOLING - WARNING) and (Refer to 19 - STEERING - WARNING).

(1) Disconnect battery negative (-) terminal.

(2) Remove the accessory drive belt (Refer to 7 - COOLING/ACCESSORY DRIVE/DRIVE BELT - REMOVAL).

(3) Remove power steering fluid reservoir. (Refer to 19 - STEERING/PUMP/RESERVOIR - REMOVAL)

(4) Remove generator. (Refer to 8 - ELECTRICAL/CHARGING/GENERATOR - REMOVAL)

(5) Drain engine coolant (Refer to 7 - COOLING/ENGINE - STANDARD PROCEDURE - DRAIN COOLING SYSTEM).

(6) If equipped with air conditioning, remove A/C compressor upper mounting bolts.

(7) Raise vehicle (Refer to LUBRICATION & MAINTENANCE/HOISTING - STANDARD PROCEDURE).

(8) Remove accessory drive belt splash shield.

(9) If equipped with air conditioning, remove A/C compressor lower mounting bolts. Reposition A/C compressor to allow access to power steering pump/water pump lower mounting bolts. Do not overextend A/C hoses while performing this.

(10) Remove radiator hose at inlet to water pump.

(11) Remove heater tube hose at water pump.

(12) Lower vehicle.

(13) Remove the bolt fastening the power steering pressure hose to the reservoir bracket (Fig. 28).

(14) Back out the tube nut securing the power steering fluid pressure hose to the power steering pump and remove the hose from the pump (Fig. 28). Cap off hose end and pump pressure port.

(15) Remove coolant outlet connector hose at water pump outlet.

(16) Remove all four power steering pump mounting bolts. (Fig. 29)

(17) Remove power steering pump and water pump as an assembly.

(18) To separate the power steering pump from the water pump, (Refer to 7 - COOLING/ENGINE/WATER PUMP - DISASSEMBLY).

(19) If the power steering pump pulley needs to be removed, (Refer to 19 - STEERING/PUMP - DISASSEMBLY).

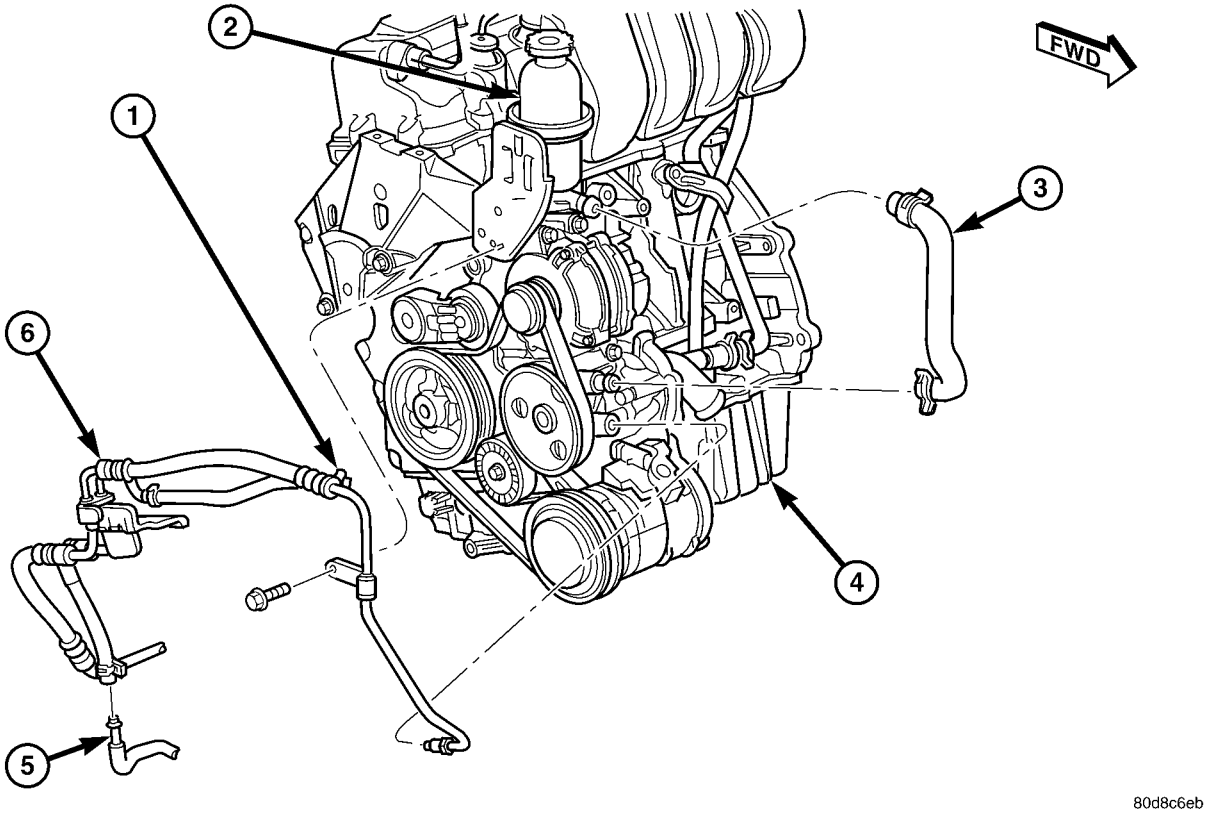

Fig. 28 Hoses, Reservoir And Pump - 1.6L Engine

1 - RETURN HOSE
2 - FLUID RESERVOIR
3 - SUPPLY HOSE
4 - 1.6L ENGINE
5 - COOLER OUTLET TUBE
6 - PRESSURE HOSE

DISASSEMBLY

(1) Remove the three hex drive bolts and washers that attach the power steering pump to the water pump (Fig. 27).

(2) Use the following steps to access the water pump impeller hex.

(a) Place a ¼ inch drive 10 mm socket in through the coolant inlet tube, then back it into the heater hose fitting area as shown (Fig. 30). Backing the socket into the heater hose fitting makes it easier to perform the following step.

(b) Holding the socket in this position, insert a ¼ inch drive extension (6 inches in length or longer) in through the heater hose fitting into the rear of the 10 mm socket.

(c) Push the socket with the extension into the pump placing the socket on the hex built into the center of the water pump impeller.

(3) While holding the power steering pump shaft from turning using a hex wrench in the pulley end of the shaft, loosen the impeller by rotating the ¼ inch drive extension counterclockwise using a ratchet. The water pump will rise off of the power steering pump as the impeller is rotated.

(4) Once the threads have been disengaged, remove the entire water pump assembly from the power steering pump. **If the water pump will be used again, the 10 mm socket and extension can be left inside the water pump until reassembly is completed.**

(5) If the water pump inlet cover needs to be removed, remove the seven fasteners around the perimeter of the pump and remove the cover. Discard the housing O-ring type seal.

(6) If the power steering pump pulley needs to be removed, (Refer to 19 - STEERING/PUMP - DISASSEMBLY).

NOTE: For reassembly, (Refer to 7 - COOLING/ENGINE/WATER PUMP - ASSEMBLY).

WATER PUMP/POWER STEERING PUMP ASSEMBLY (Continued)

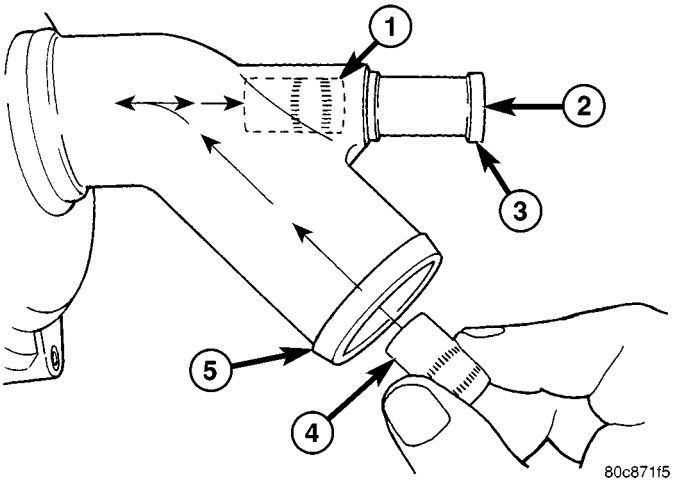

Fig. 30 Inserting Socket into Pump Inlet

1 - SOCKET LOCATION ONCE PLACED INSIDE COOLANT INLET
2 - INSERT EXTENSION THROUGH HERE INTO SOCKET
3 - HEATER HOSE FITTING
4 - 10 MM SOCKET (¼ INCH DRIVE)
5 - COOLANT INLET

ASSEMBLY

(1) If the water pump inlet cover needs to be installed on the water pump:

(a) First apply Mopar® Dielectric Grease or equivalent to a NEW water pump O-ring seal.

(b) Place the O-ring seal in the housing groove where the cover contacts the housing.

(c) Install the seven fasteners around the perimeter of the pump. Tighten them to 12 N·m (105 in. lbs.) torque.

(2) If a pulley needs to be installed on the power steering pump, (Refer to 19 - STEERING/PUMP - ASSEMBLY).

(3) Place the water pump assembly onto the power steering pump shaft.

(4) Rotate the water pump so the water pump outlet is near the water pump upper mounting holes (hole with dowel guide). Arrange the three pump fastener holes so they line up.

(5) If the water pump impeller hex has not been accessed with a socket, use the following steps to access the water pump impeller hex.

(a) Place a ¼ inch drive 10 mm socket in through the coolant inlet tube, then back it into the heater hose fitting area as shown (Fig. 30).

(b) Holding the socket in this position, insert a ¼ inch drive extension (6 inches in length or longer) in through the heater hose fitting into the rear of the 10 mm socket.

(c) Push the socket with the extension into the pump placing the socket on the hex built into the center of the water pump impeller.

(6) While holding the power steering pump shaft from turning using a hex wrench in the pulley end of the shaft, tighten the water pump impeller rotating the ¼ inch drive extension clockwise using a ratchet. This will draw the water pump in toward the power steering pump. Tighten the impeller to 26 N·m (19 ft. lbs.) torque.

(7) Remove the 10 mm socket, ¼ inch extension and ratchet from the water pump. Remove the hex wrench.

(8) Align the three pump fastener holes and install the three hex drive bolts with washers (Fig. 27). Tighten the bolts to 26 N·m (19 ft. lbs.) torque.

(9) Install assembly on the vehicle. (Refer to 7 - COOLING/ENGINE/WATER PUMP - INSTALLATION)

INSTALLATION

NOTE: Water pump and power steering pump must be attached to one another before installation in vehicle. For proper procedure, (Refer to 7 - COOLING/ENGINE/WATER PUMP - ASSEMBLY).

(1) Install water pump/power steering pump assembly into engine compartment in reverse of how it was removed.

(2) Install all four power steering pump mounting bolts (Fig. 29). Tighten bolts to 28 N·m (21 ft. lbs.) torque.

(3) Install coolant outlet connector hose at water pump outlet. Install clamp.

WATER PUMP/POWER STEERING PUMP ASSEMBLY (Continued)

(4) Using a lint free towel, wipe clean the open power steering hose end and the power steering pump port. Replace the used O-ring with new. Lubricate the O-ring with power steering fluid.

(5) Attach the power steering fluid pressure hose to the pump outlet port (Fig. 28). Do not tighten the tube nut at this time.

(6) Install the bolt fastening the power steering pressure hose to the reservoir bracket (Fig. 28).

(7) Tighten power steering pressure hose tube nut at power steering pump to 28 N·m (21 ft. lbs.) torque.

(8) Raise vehicle.

(9) Install heater tube hose at water pump fitting. Install clamp.

(10) Install radiator hose at inlet to water pump. Install clamp.

(11) If equipped with air conditioning:

(a) Position A/C compressor, align mounting holes and install, but do not fully tighten, A/C compressor lower and upper mounting bolts.

(b) Lower vehicle.

(c) Tighten A/C compressor upper mounting bolts to 28 N·m (21 ft. lbs.) torque.

(d) Raise vehicle.

(e) Tighten A/C compressor lower mounting bolts to 28 N·m (21 ft. lbs.) torque.

(12) Install drive belt splash shield.

(13) Lower vehicle.

(14) Install generator (Refer to 8 - ELECTRICAL/CHARGING/GENERATOR - INSTALLATION).

(15) Install power steering fluid reservoir. (Refer to 19 - STEERING/PUMP/RESERVOIR - INSTALLATION)

(16) Install accessory drive belt (Refer to 7 - COOLING/ACCESSORY DRIVE/DRIVE BELT - INSTALLATION).

(17) Connect battery negative (-) terminal.

(18) Fill cooling system (Refer to 7 - COOLING - STANDARD PROCEDURE - FILLING COOLING SYSTEM).

(19) Perform POWER STEERING PUMP INITIAL OPERATION procedure. (Refer to 19 - STEERING/PUMP - STANDARD PROCEDURE)

(20) Check for leaks at all hose connections.

ENGINE - 2.0/2.4L DOHC

DESCRIPTION

Non-Turbo

The cooling system consists of an engine cooling module, thermostat, coolant recovery/reserve system, coolant, and a water pump. The engine cooling module (Fig. 1) consists of a radiator, electric fan motor, fan, shroud, transmission oil cooler, hoses, clamps, air conditioning condenser and transmission oil lines.

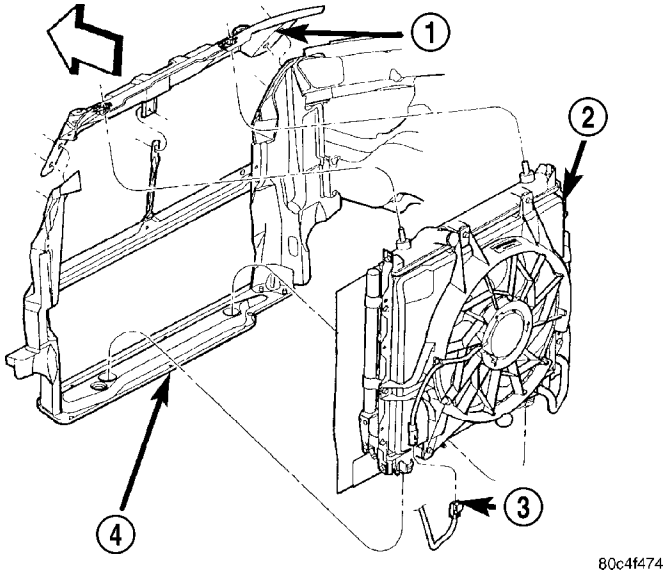

Fig. 1 Cooling Module

1 - UPPER RADIATOR CLOSURE PANEL
2 - COOLING MODULE
3 - RADIATOR FAN CONNECTOR
4 - LOWER RADIATOR CROSSMEMBER

Turbo

The cooling system consists of an engine cooling module, thermostat, coolant recovery/reserve system, coolant, and a water pump. The engine cooling module (Fig. 2) consists of a radiator, electric fan assembly, transmission oil cooler, charge air cooler, hoses, clamps, air conditioning condenser and transmission oil lines. Turbocharged equipped vehicles utilize the radiator in-tank cooler for a power steering fluid cooler.

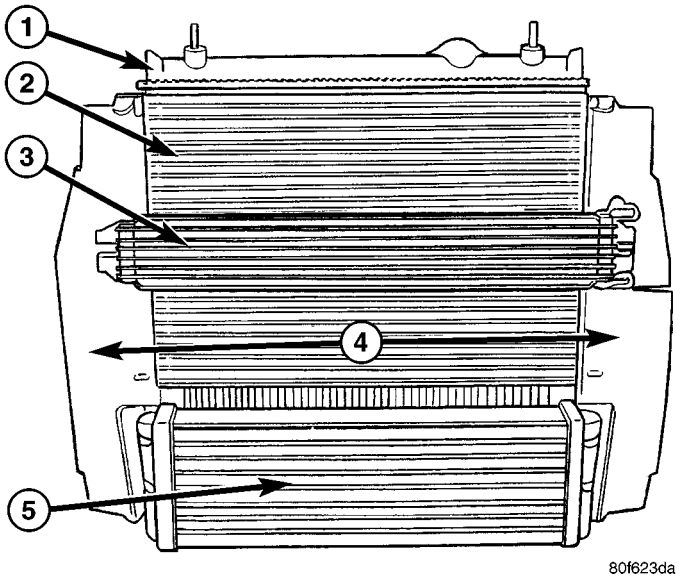

Fig. 2 Cooling Module - 2.4L Turbo

2 - A/C CONDENSER
3 - AUTOMATIC TRANSMISSION OIL COOLER
4 - AIR SEALS
5 - CHARGE AIR COOLER

ENGINE - 2.0/2.4L DOHC (Continued)

OPERATION

The cooling systems primary purpose is to maintain engine temperature in a range that will provide satisfactory engine performance and emission levels under all expected driving conditions. The system does this by transferring heat from the engine metal to the coolant, then moves this heated coolant to the radiator where this heat is transferred to the ambient air. It also provides hot water (coolant) for heater performance and cooling for the automatic transmission oil.

- When the Engine is cold: The thermostat is closed and the cooling system has no flow through the radiator. The coolant flows through the engine, heater system which also serves as the bypass.
- When the Engine is warm: Thermostat is open and the cooling system has flow through the radiator, engine, heater system which also serves as the bypass.

The coolant flow circuit is shown in (Fig. 3).

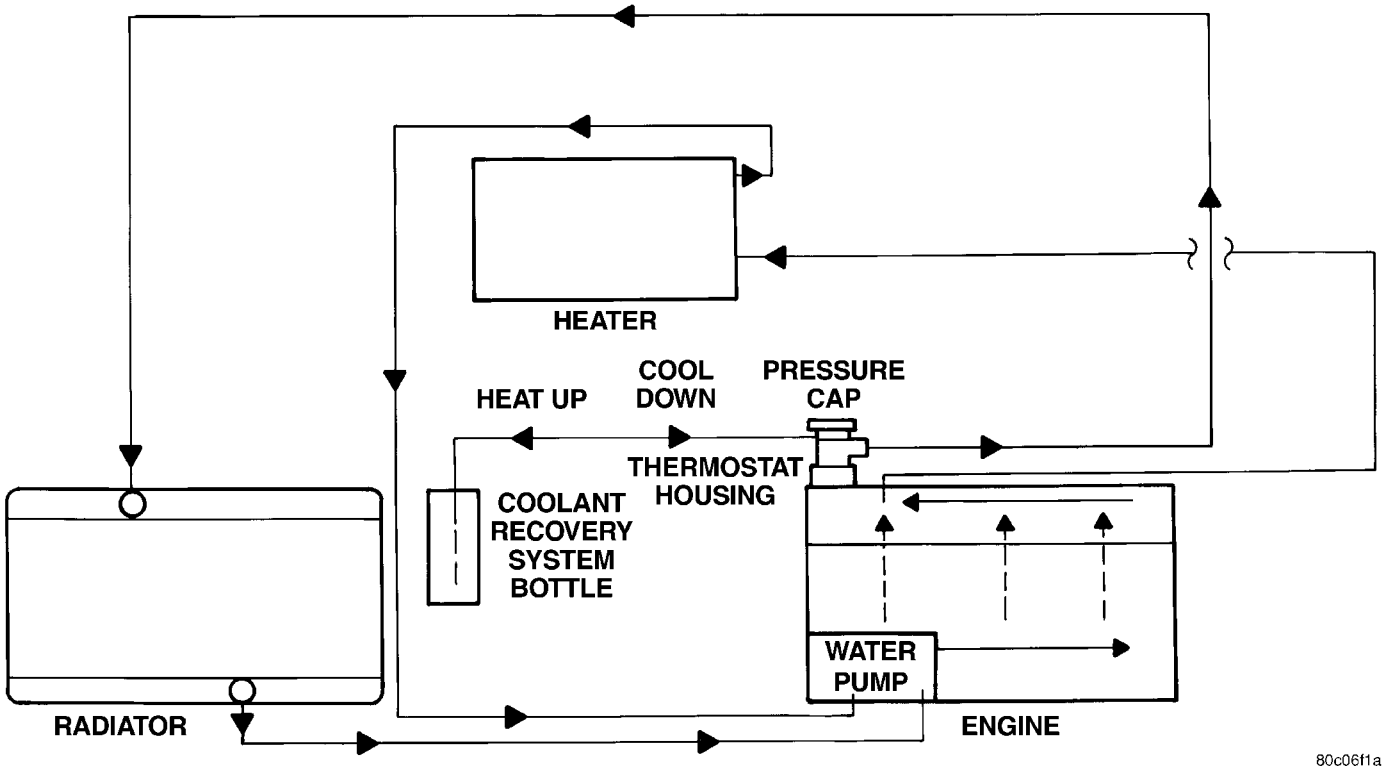

Fig. 3 Cooling System Operation

ENGINE - 2.0/2.4L DOHC (Continued)

DIAGNOSIS AND TESTING

COOLING SYSTEM

CONDITION	POSSIBLE CAUSE	CORRECTION
TEMPERATURE GAUGE READS LOW	1. Diagnostic Trouble Code (DTC) has been set indicating a stuck open engine thermostat.	1. Replace thermostat, if necessary. If a (DTC) has not been set, the problem may be with the temperature gauge.
	2. Engine Coolant Temperature Sensor.	2. Check connector at Engine Coolant Temperature Sensor. Repair as necessary.
	3. Faulty temperature gauge.	3. Check gauge operation (Refer to 8 - ELECTRICAL/INSTRUMENT CLUSTER - DIAGNOSIS AND TESTING).
	4. Coolant level low during cold ambient temperature, accompanied by poor heater performance.	4. Check coolant level in the coolant recovery/reserve container and the radiator. Inspect the system for leaks. Repair as necessary. Refer to WARNINGS in this section before removing pressure cap.
TEMPERATURE GAUGE READS HIGH OR ENGINE COOLANT WARNING LAMP ILLUMINATES. COOLANT MAY OR MAY NOT BE LOST FROM SYSTEM.	1. Trailer being towed, a steep hill being climbed, vehicle being operated in slow moving traffic, or engine idling during high ambient (outside) temperatures with air conditioning on. High altitudes could also cause these conditions.	1. This may be a temporary condition and repair is not necessary. Turn off the air conditioning and drive the vehicle without any of the previous conditions. Observe the temperature gauge the gauge should return to the normal range. If the gauge does not return to the normal range, determine the cause of the overheating and repair. Refer to POSSIBLE CAUSES in this section.
	2. Faulty temperature gauge.	2. Check gauge operation (Refer to 8 - ELECTRICAL/INSTRUMENT CLUSTER - DIAGNOSIS AND TESTING).
	3. Is temperature warning lamp (if equipped) illuminating unnecessarily?	3. Check warning lamp operation (Refer to 8 - ELECTRICAL/ INSTRUMENT CLUSTER - DIAGNOSIS AND TESTING).
	4. Coolant low in recovery/reserve bottle and radiator?	4. Check for coolant leaks and repair as necessary.
	5. Pressure cap not installed tightly. If cap is loose, boiling point of coolant will be lowered. Also refer to the following step 6.	5. Tighten cap.

ENGINE - 2.0/2.4L DOHC (Continued)

CONDITION	POSSIBLE CAUSE	CORRECTION
	6. Poor seals at pressure cap.	6. (a) Check condition of cap and cap seals (Refer to 7 - COOLING/ ENGINE/RADIATOR PRESSURE CAP - DIAGNOSIS AND TESTING). Replace cap if necessary. (b) Check condition of filler neck. If neck is warped or damaged, replace neck.
	7. Coolant level low in radiator, but not in coolant recovery/reserve bottle. This indicates the radiator is not drawing coolant from the coolant recovery/reserve bottle as the engine cools. As the engine cools, a vacuum is formed inside the cooling system. If the pressure cap seals are defective, or the cooling system has a leak, a vacuum cannot be formed.	7. (a) Check condition of pressure cap and cap seals. Replace cap if necessary. (b) Check condition of filler neck. Replace if damaged. (c) Check condition of hose from filler neck to coolant container. It should be tight at both ends without any kinks or tears. Replace hose as necessary. (d) Check coolant recovery/reserve bottle and hose for blockage. Repair as necessary.
	8. Freeze point of coolant not correct. Mixture ratio may be too rich.	8. Check coolant concentration (Refer to 7 - COOLING/ENGINE/ COOLANT - DIAGNOSIS AND TESTING). Adjust glycol-to-water ratio as required.
	9. Coolant not flowing through system.	9. Check for coolant flow at filler neck with some coolant removed, engine warm, and thermostat open. Coolant should be observed flowing through filler neck. If flow is not observed, determine reason for lack of flow and repair as necessary.
	10. Radiator air seals missing or improperly installed.	10. Inspect air seals. Correct as necessary.
	11. Radiator or A/C condenser fins are dirty or clogged.	11. Clean obstruction from fins.
	12. Radiator core is plugged or corroded.	12. Replace or clean radiator.
	13. Fuel or ignition system problems.	13. Refer to the appropriate Powertrain Diagnostic Procedure manual.
	14. Dragging Brakes.	14. Inspect brake system and repair as necessary (Refer to 5 - BRAKES - DIAGNOSIS AND TESTING).
	15. Bug screen or other aftermarket accessory is being used causing reduced air flow.	15. Remove bug screen or accessory.

ENGINE - 2.0/2.4L DOHC (Continued)

CONDITION	POSSIBLE CAUSE	CORRECTION
	16. Thermostat partially or completely closed.	16. Check thermostat operation and replace as necessary (Refer to 7 - COOLING/ENGINE/ENGINE COOLANT THERMOSTAT - DIAGNOSIS AND TESTING).
	17. Cooling fan not operating properly.	17. Check electric fan operation and repair as necessary.
	18. Cylinder head gasket leaking.	18. Check cylinder head gasket for leaks (Refer to 7 - COOLING/ ENGINE - DIAGNOSIS AND TESTING - COOLING SYSTEM LEAK TESTING).
	19. Heater core leaking.	19. Check heater core for leaks.
TEMPERATURE GAUGE READING IS INCONSISTENT (FLUCTUATES, CYCLES OR IS ERRATIC)	1. The gauge may cycle up and down. This is due to the cycling of the electric radiator fan.	1. A normal condition. No correction is necessary. If gauge cycling is the hot zone, check electric fan operation and repair as necessary.
	2. During cold weather operation with the heater blower in the high position, the gauge reading may drop slightly.	2. A normal condition. No correction is necessary.
	3. Temperature gauge or Engine Coolant Temperature Sensor is defective or shorted.	3. Check gauge operation (Refer to 8 - ELECTRICAL/INSTRUMENT CLUSTER - DIAGNOSIS AND TESTING).
	4. Gauge reading rises when vehicle is brought to a stop after heavy use (engine still running).	4. A normal condition. No correction is necessary. The gauge should return to normal range after vehicle is driven.
	5. Gauge reading high after restarting a warmed-up (hot) engine.	5. A normal condition. No correction is necessary. The gauge should return to normal range after a few minutes of engine operation.
	6. Coolant level low in radiator (air will build up in the cooling system causing the thermostat to open late).	6. Check and correct coolant leaks.
	7. Cylinder head gasket leaking allowing exhaust gas to enter cooling system. This will cause thermostat to open late.	7. (a) Check for cylinder head gasket leaks using Tool C-3685-A Block Leak Tester or the equivalent. Repair as necessary. (b) Check for coolant in the engine oil. Inspect for white steam emitting from exhaust system. Repair as necessary.
	8. Water pump impeller loose on shaft.	8. Check water pump and replace as necessary.

ENGINE - 2.0/2.4L DOHC (Continued)

CONDITION	POSSIBLE CAUSE	CORRECTION
	9. Air leak on the suction side of water pump allows air to build up in cooling system. This will cause the thermostat to open late.	9. Locate leak and repair as necessary.
PRESSURE CAP IS BLOWING OFF STEAM AND/OR COOLANT FLOWING INTO RECOVERY BOTTLE. TEMPERATURE GAUGE READING MAY BE ABOVE NORMAL, BUT NOT HIGH. COOLANT LEVEL MAY BE HIGH IN RECOVERY BOTTLE.	1. Pressure relief valve in pressure cap is defective.	1. Check condition of pressure cap and seals (Refer to 7 - COOLING/ ENGINE/RADIATOR PRESSURE CAP - DIAGNOSIS AND TESTING). Replace as necessary.
COOLANT LOSS TO THE GROUND WITHOUT PRESSURE CAP BLOWOFF. GAUGE IS READING HIGH OR HOT.	1. Coolant leaks in radiator, cooling system hoses, water pump or engine.	1. Pressure test cooling system and repair as necessary.
DETONATION OR PRE-IGNITION (NOT CAUSED BY IGNITION SYSTEM). GAUGE MAY OR MAY NOT BE READING HIGH.	1. Engine overheating. 2. Freeze point of coolant not correct.	1. Check reason for overheating and repair as necessary. 2. Check the freeze point of the coolant (Refer to 7 - COOLING/ ENGINE/COOLANT - DIAGNOSIS AND TESTING). Adjust glycol-to-water ratio as required.
HOSE OR HOSES COLLAPSE WHEN ENGINE IS COOLING	1. Vacuum created in cooling system on engine cool-down is not being relieved through coolant recovery/reserve system.	1. (a) Pressure cap relief valve stuck (Refer to 7 - COOLING/ ENGINE/RADIATOR PRESSURE CAP - DIAGNOSIS AND TESTING). Replace as necessary. (b) Hose between coolant recovery/reserve bottle and outlet connector is kinked. Repair as necessary. (c) Vent at coolant recovery/reserve bottle is plugged. Clean vent and repair as necessary. (d) Recovery/reserve bottle is internally blocked or plugged. Check for blockage and repair as necessary.
RADIATOR FAN OPERATES ALL THE TIME	1. Malfunctioning electrical component or circuit. 2. Check for low coolant level.	1. Refer to appropriate Powertrain Diagnostic Procedures. Repair as necessary. 2. Repair as necessary.

ENGINE - 2.0/2.4L DOHC (Continued)

CONDITION	POSSIBLE CAUSE	CORRECTION
RADIATOR FAN WILL NOT OPERATE, GAUGE READING HIGH OR HOT	1. Fan motor defective.	1. Refer to appropriate Powertrain Diagnostic Procedures manual for operation of the DRB III® scan tool. Repair as necessary.
	2. Fan relay, powertrain control module (PCM) or engine coolant temperature sensor defective.	2. Refer to appropriate Powertrain Diagnostic Procedures manual for operation of the DRB III® scan tool. Repair as necessary.
	3. Blown fuse in power distribution center (PDC).	3. Determine cause for blown fuse and repair as necessary.
NOISY FAN	1. Fan blade loose.	1. Replace radiator fan assembly.
	2. Fan blade striking a surrounding object.	2. Locate point of fan blade contact and repair as necessary.
	3. Air obstructions at radiator or A/C condenser.	3. Remove obstructions and/or clean debris from radiator and/or A/C condenser.
	4. Electric fan motor defective.	4. Replace radiator fan assembly.
INADEQUATE AIR CONDITIONER PERFORMANCE (COOLING SYSTEM SUSPECTED)	1. Electric radiator fan not operating when A/C is on.	1. Refer to appropriate Powertrain Diagnostic Procedures manual for operation of the DRB III® scan tool. Repair as necessary.
	2. Radiator and/or air conditioning condenser is restricted, obstructed or dirty.	2. Remove restriction and/or clean as necessary.
	3. Radiator air seals missing or improperly installed.	3. Inspect air seals. Repair as necessary.
	4. Engine is overheating (heat may be transferred from radiator to A/C condenser). High underhood temperature due to engine overheating may also transfer heat to A/C components.	4. Correct overheating condition. Refer to this section.
INADEQUATE HEATER PERFORMANCE	1. Has a diagnostic trouble code (DTC) been set?	1. Refer to Powertrain Diagnostic Procedures.
	2. Coolant level low.	2. Check cooling system for leaks. Repair as necessary.
	3. Obstructions in heater hose fittings at engine.	3. Remove heater hoses at both ends and check for obstructions. Repair as necessary.
	4. Heater hose kinked.	4. Locate kinked area and repair as necessary.
	5. Water pump is not pumping coolant to heater core. When the engine is fully warmed up, both heater hoses should be hot to the touch.	5. (Refer to 7 - COOLING/ENGINE/ WATER PUMP - DIAGNOSIS AND TESTING). Repair as necessary.

ENGINE - 2.0/2.4L DOHC (Continued)

CONDITION	POSSIBLE CAUSE	CORRECTION
HEAT ODOR	1. Various heat shields are used at certain components. One or more of these shields may be missing.	1. Locate missing shields and replace or repair as necessary.
	2. Is temperature gauge reading above the normal range?	2. Refer to the previous Temperature Gauge Reads High in these Diagnostic Charts. Repair as necessary.
	3. Is cooling fan operating correctly?	3. Repair as necessary.
	4. Has undercoating been applied to any unnecessary component.	4. Clean undercoating as necessary.
	5. Engine may be running rich causing the catalytic converter to overheat.	5. Refer to appropriate Powertrain Diagnostic Procedures manual for operation of the DRB III® scan tool. Repair as necessary.
POOR DRIVEABILITY (THERMOSTAT POSSIBLY STUCK OPEN). GAUGE MAY BE READING LOW	1. Has a diagnostic trouble code (DTC) been set?	1. Refer to the Powertrain Diagnostic Procedure manual for checking a DTC related to the thermostat.
STEAM IS COMING FROM FRONT OF VEHICLE NEAR GRILL AREA WHEN WEATHER IS WET, ENGINE IS WARMED UP, RUNNING, AND VEHICLE IS STATIONARY. TEMPERATURE GAUGE IS IN NORMAL RANGE.	1. During wet weather, moisture (snow, ice or rain condensation) on the radiator will evaporate when the thermostat opens. This opening allows heated water into the radiator. When the moisture contact the hot radiator, steam may be emitted. This usually occurs in cold weather with no fan or airflow to blow it away.	1. Occasional steam emitting from this area is normal. No repair is necessary.
COOLANT COLOR	1. Coolant color is not necessarily an indication of adequate corrosion or temperature protection. Do not rely on coolant color for determining condition of coolant.	1. Check the freeze point of the coolant (Refer to 7 - COOLING/ ENGINE/COOLANT - DIAGNOSIS AND TESTING). Adjust the glycol-to-water ratio as required.
COOLANT LEVEL CHANGES IN COOLANT RECOVERY/RESERVE BOTTLE	1. Level changes are to be expected as coolant volume fluctuates with engine temperature. If the level in the bottle was between the FULL HOT and ADD marks at normal engine operating temperature, the level should return to within that range after operation at elevated temperatures.	1. A normal condition. No repair is necessary.

ENGINE - 2.0/2.4L DOHC (Continued)

DIAGNOSIS AND TESTING - COOLING SYSTEM LEAK TESTING

WARNING: IF VEHICLE HAS BEEN RUN RECENTLY, WAIT 15 MINUTES BEFORE REMOVING PRESSURE CAP. PLACE A SHOP TOWEL OVER THE CAP, AND WITHOUT PUSHING DOWN, ROTATE IT COUNTER-CLOCKWISE TO THE FIRST STOP. ALLOW FLUIDS TO ESCAPE THROUGH THE OVERFLOW TUBE. WHEN THE SYSTEM STOPS PUSHING COOLANT AND STEAM INTO THE COOLANT RECOVERY BOTTLE AND PRESSURE DROPS, PUSH DOWN ON THE CAP AND REMOVE IT COMPLETELY. SQUEEZING THE RADIATOR INLET HOSE WITH A SHOP TOWEL (TO CHECK PRESSURE) BEFORE AND AFTER TURNING TO THE FIRST STOP IS RECOMMENDED.

The cooling system should be full. Add coolant if necessary.

With engine not running, wipe the coolant filler neck sealing seat clean.

Attach a cooling system pressure tester (Special Tool 7700 or equivilent) to the coolant filler neck, as shown in (Fig. 4) and apply 104 kPa (15 psi) pressure. If the pressure drops more than 2 psi in 2 minutes inspect all points for external leaks. For Special Tool identification, (Refer to 7 - COOLING - SPECIAL TOOLS).

Move all hoses at the radiator and heater while system is pressurized at 104 kPa (15 psi), since some leaks occur while driving due to engine movement while driving.

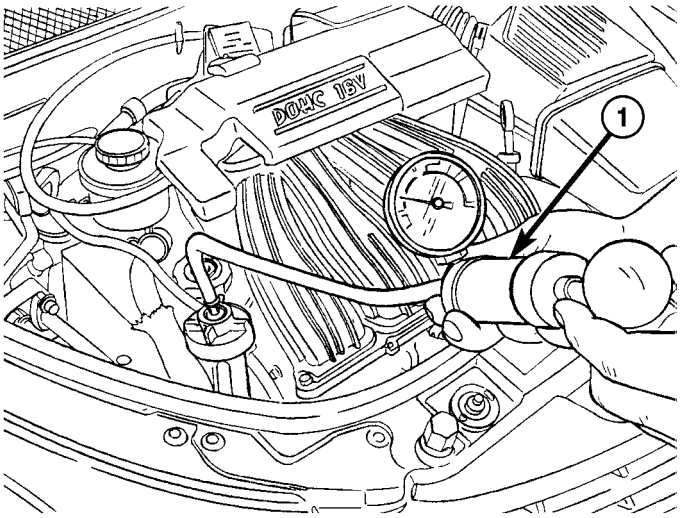

Fig. 4 Pressure Testing Cooling System

1 - SPECIAL TOOL 7700

If there are no external leaks after the gauge dial shows a drop in pressure, detach the tester. Start engine and run the engine to normal operating temperature in order to open the thermostat and allow the coolant to expand. Reattach the tester. If the needle on the dial fluctuates, it indicates a combustion leak and is usually a head gasket leak.

WARNING: WITH TOOL IN PLACE PRESSURE BUILDS UP FAST. ANY EXCESSIVE AMOUNT OF PRESSURE BUILT UP BY CONTINUOUS ENGINE OPERATION MUST BE RELEASED TO A SAFE PRESSURE POINT. NEVER PERMIT PRESSURE TO EXCEED 138 kPa (20 psi).

If the needle on the dial does not fluctuate, race the engine a few times. If an abnormal amount of coolant or steam is emitted from the tailpipe, it may indicate a faulty head gasket, cracked engine block or cylinder head.

There may be internal leaks which can be determined by removing the oil dipstick. If water globules appear intermixed with the oil, it will indicate a internal leak in the engine. If there is an internal leak, the engine must be disassembled for repair.

DIAGNOSIS AND TESTING - COOLING SYSTEM FLOW CHECK

To determine whether coolant is flowing through the cooling system, use one of the following procedures:

PREFERRED METHOD

WARNING: DO NOT REMOVE THE COOLING SYSTEM PRESSURE CAP OR ANY HOSE WITH THE SYSTEM HOT AND UNDER PRESSURE BECAUSE SERIOUS BURNS FROM COOLANT CAN OCCUR.

- Remove pressure cap when engine is cold. Remove small amount of coolant. Idle engine until thermostat opens. You should observe coolant flow while looking down the filler neck. Once flow is detected install the pressure cap. Replace removed coolant into coolant recovery container.

ALTERNATIVE METHOD

- If engine is cold, idle engine until normal operating temperature is reached. Feel the upper radiator hose. If it is hot, coolant is circulating.

COOLING SYSTEM AERATION

Low coolant level in the cooling system will cause aeration, resulting in the following conditions:

- Corrosion in the system
- High reading shown on the temperature gauge
- Loss of coolant flow through the heater
- Exhaust gas leaks into the coolant can also cause the above problems

ENGINE - 2.0/2.4L DOHC (Continued)

DIAGNOSIS AND TESTING - COOLING SYSTEM DEAERATION

Air can only be removed from the system by gathering under the pressure cap. On the next heat up it will be pushed past the pressure cap into the coolant recovery bottle by thermal expansion of the coolant. It then escapes to the atmosphere in the coolant recovery bottle and is replaced with coolant on cool down.

To effectively deaerate the system, multiple thermal cycles of the system may be required.

NOTE: Deaeration does not occur at engine idle—higher engine speeds are required. Normal driving will deaerate cooling system.

STANDARD PROCEDURE

STANDARD PROCEDURE - DRAINING COOLING SYSTEM

WARNING: DO NOT OPEN THE RADIATOR DRAINCOCK WITH THE SYSTEM HOT AND UNDER PRESSURE. SERIOUS BURNS FROM COOLANT CAN OCCUR.

NOTE: Drain, flush, and fill the cooling system at the mileage or time intervals specified in the MAINTENANCE SCHEDULE (Refer to LUBRICATION & MAINTENANCE/MAINTENANCE SCHEDULES - DESCRIPTION). If the solution is dirty, rusty, or contains a considerable amount of sediment; clean and flush with a reliable cooling system cleaner. Care should be taken in disposing of the used engine coolant from your vehicle. Check governmental regulations for disposal of used engine coolant.

(1) Position a clean collecting container under draincock location.

(2) Without removing the pressure cap and with system not under pressure, turn draincock counterclockwise to open (Fig. 5).

(3) The coolant reserve bottle should empty first, then remove the pressure cap.

(4) If coolant reserve bottle does not empty first:

(a) Check condition of the pressure cap and cap seals.

(b) Check for kinked/torn overflow hose from filler neck to reserve bottle.

(5) Allow cooling system to drain completely.

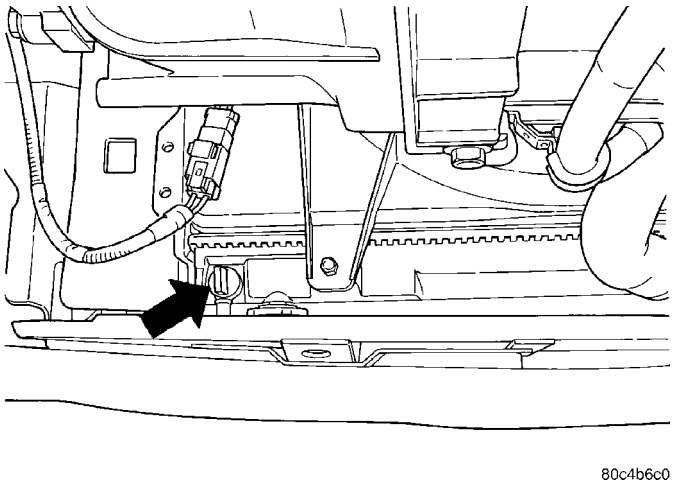

Fig. 5 Cooling System Draincock Location

STANDARD PROCEDURE - FILLING COOLING SYSTEM

WARNING: MAKE SURE ENGINE COOLING SYSTEM IS COOL BEFORE REMOVING PRESSURE CAP OR ANY HOSE. THE COOLING SYSTEM IS PRESSURIZED WHEN HOT. SEVERE PERSONAL INJURY MAY RESULT FROM ESCAPING HOT COOLANT.

CAUTION: Do not use well water, or suspect water supply in cooling system. A 50/50 mixture of the recommended ethylene glycol and distilled water is recommended. For recommended coolant usage, (Refer to LUBRICATION & MAINTENANCE/FLUID TYPES - DESCRIPTION).

NOTE: For cooling system capacity (Refer to LUBRICATION & MAINTENANCE/SPECIFICATIONS - FLUID CAPACITIES).

(1) Close radiator draincock. Hand tighten only.

(2) Open, but do not remove cooling system bleed valve (Fig. 6).

(3) Attach a 6.35 mm (0.250 in.) inside diameter clear hose that is 120.0 cm (48 in.) long to the bleed valve. Route the hose away from the accessory drive belts and radiator fan. Position the other end of the hose into a collecting container. The hose will prevent coolant from contacting the accessory drive belts, A/C compressor, and other components.

(4) Remove the cooling system pressure cap. Install Special Tool 8195 Filling Aid Funnel (Fig. 7).

(5) Use the supplied clip to pinch overflow hose (Fig. 7).

NOTE: Be careful not to spill coolant on drive belts or the generator.

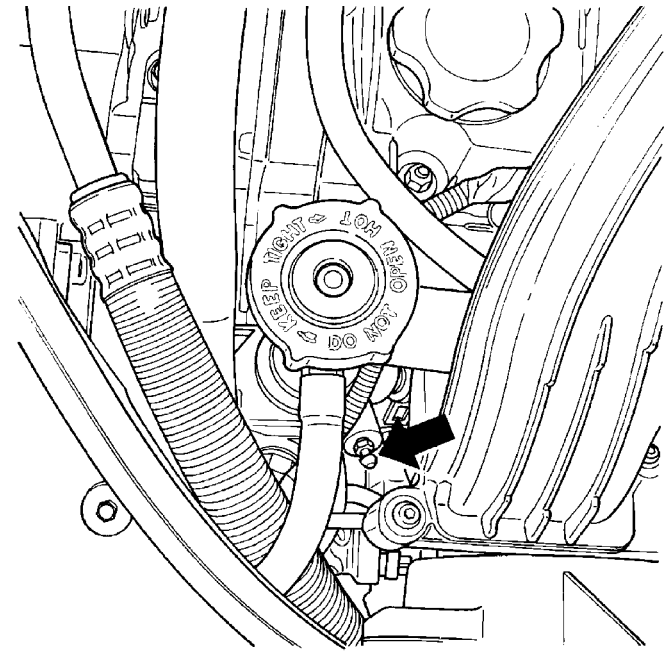

Fig. 6 Cooling System Bleed Valve

NOTE: While filling the cooling system, pour coolant into the larger section of the Filling Aid Funnel 8195.

(6) Slowly fill the cooling system until a steady stream of coolant flows from the attached hose on the bleed valve.

(7) Close the bleed valve and remove the hose.

(8) Remove clip from overflow hose and remove funnel 8195.

(9) Fill coolant to the top of the pressure cap neck.

(10) Install cooling system pressure cap.

CAUTION: Coolant may leak out of the bottle overflow tube if filling too rapidly.

(11) Slowly fill coolant reserve/recovery bottle to at least the FULL HOT mark with the recommended coolant. It may be necessary to add additional coolant to the reserve/recovery bottle after three or four warm-up/cool down cycles to maintain coolant level between the FULL HOT and ADD marks.This is due to the removal of trapped air from the system.

CLEANING

CAUTION: Internal radiator pressure must not exceed 138 kPa (20 psi) as damage to radiator may result.

Reverse flushing of cooling system is the forcing of water through the cooling system. This is done using air pressure in the opposite direction of normal coolant flow. It is usually only necessary with very dirty systems with evidence of partial plugging.

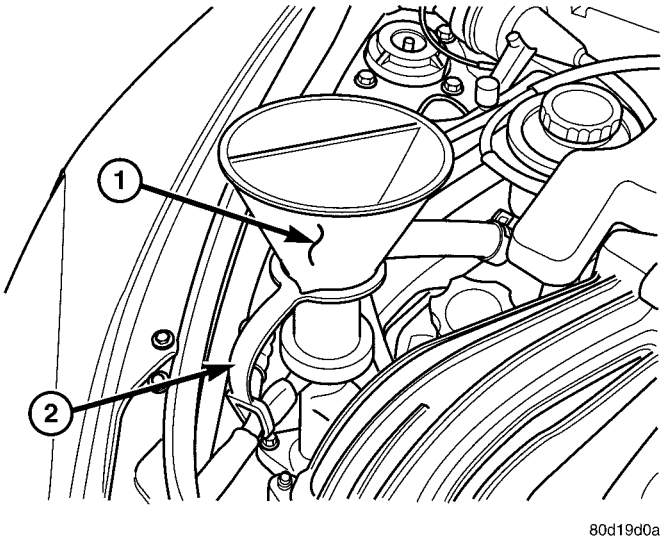

Fig. 7 Filling the Cooling System

1 - SPECIAL TOOL 8195 FILLING AID FUNNEL
2 - PINCH OVERFLOW HOSE

(1) Drain cooling system. Remove thermostat housing and thermostat. Install thermostat housing.

(2) Connect a suitable cooling system flusher and follow instructions supplied with flusher.

INSPECTION

After performing a cleaning/flush procedure, inspect all hoses, clamps and connections for deterioration and leaks. Inspect radiator and heater core for leaks.

COOLANT

DESCRIPTION

CAUTION: Use of Propylene Glycol based coolants is not recommended, as they provide less freeze protection and less corrosion protection. Do not mix coolant types. If coolant other than Mopar® Antifreeze/Coolant, 5 Year/100,000 Mile Formula or equivalent is added, the mixed coolant will have a reduced service schedule.

The use of aluminum cylinder heads, and water pumps requires special corrosion protection. Mopar® Antifreeze/Coolant, 5 Year/100,000 Mile Formula or equivalent ethylene glycol based coolant with corrosion inhibitors (called HOAT, for Hybrid Organic Additive Technology) is recommended. This coolant offers the best engine cooling without corrosion when mixed with 50% Ethylene Glycol and 50% distilled

COOLANT (Continued)

water to obtain a freeze point of -37°C (-35°F). If it loses color or becomes contaminated, drain, flush, and replace with fresh properly mixed coolant solution. Mixing of coolants other than specified (non-HOAT), will reduce the 5 year/100,000 mile corrosion protection.

DIAGNOSIS AND TESTING - COOLANT CONCENTRATION TESTING

Coolant concentration should be checked when any additional coolant was added to system or after a coolant drain, flush and refill. The coolant mixture offers optimum engine cooling and protection against corrosion when mixed to a freeze point of -37°C (-34°F) to -46°C (-50°F). The use of a hydrometer or a refractometer can be used to test coolant concentration.

A hydrometer will test the amount of glycol in a mixture by measuring the specific gravity of the mixture. The higher the concentration of ethylene glycol, the larger the number of balls that will float, and higher the freeze protection (up to a maximum of 60% by volume glycol).

A refractometer (Special Tool 8286)(Refer to 7 - COOLING - SPECIAL TOOLS) will test the amount of glycol in a coolant mixture by measuring the amount a beam of light bends as it passes through the fluid.

Some coolant manufactures use other types of glycols into their coolant formulations. Propylene glycol is the most common new coolant. However, propylene glycol based coolants do not provide the same freezing protection and corrosion protection and is not recommended.

CAUTION: Do not mix types of coolant—corrosion protection will be severely reduced.

STANDARD PROCEDURE

STANDARD PROCEDURE - ROUTINE COOLANT LEVEL CHECK

NOTE: Do not remove pressure cap for routine coolant level inspections.

The coolant recovery/reserve system provides a quick visual method for determining the coolant level without removing the pressure cap. Simply observe, with the engine idling and warmed up to normal operating temperature, that the level of the coolant in the recovery/reserve bottle (Fig. 8) is between the FULL HOT and ADD marks.

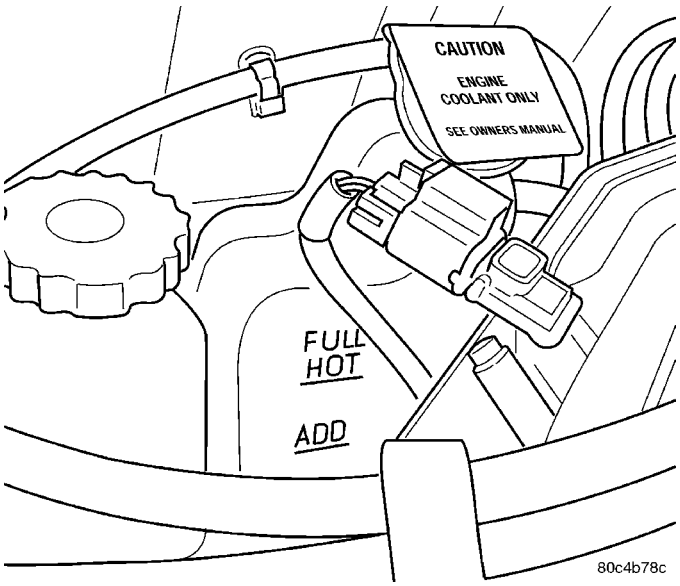

Fig. 8 Coolant Level

STANDARD PROCEDURE - ADDING ADDITIONAL COOLANT

NOTE: The radiator cap should not be removed.

When additional coolant is needed, it should be added to the coolant recovery container (Fig. 9) or (Fig. 10). Use only the recommended 50/50 mixture of ethylene glycol type antifreeze and distilled water (Refer to 7 - COOLING/ENGINE/COOLANT - DESCRIPTION).

CAUTION: COOLANT MAY LEAK OUT OF THE BOTTLE OVERFLOW TUBE WHILE FILLING RAPIDLY.

STANDARD PROCEDURE - COOLANT LEVEL SERVICING

NOTE: The cooling system is closed and designed to maintain coolant level to the top of the radiator.

When servicing requires a coolant level check in the radiator, the engine must be **off** and **not** under pressure. Drain several ounces of coolant from the radiator drain cock while observing the coolant recovery container. Coolant level in the container should drop slightly. Remove the pressure cap (Fig. 9) or (Fig. 10). The radiator should be full to the top. If not, and the coolant level in the recovery contianer is at the ADD mark, there is a air leak in the coolant recovery system. Check hose or hose connections to the recovery container, outlet connector neck or the pressure cap seal at outlet connector for leaks.

COOLANT RECOVERY CONTAINER

DESCRIPTION

The coolant recovery system consists of a coolant recovery container mounted to the dash panel, a vent hose for the coolant recovery container, a hose connecting the container to the coolant outlet connector on the engine, and a pressure cap (Fig. 12) and (Fig. 14).

OPERATION

The system works in conjunction with the cooling system pressure cap to utilize thermal expansion and contraction of the coolant to keep the coolant free of trapped air. The system provides space for expansion and contraction. Also, the system provides a convenient and safe method for checking and adjusting the coolant level at atmospheric pressure without removing the pressure cap. It also provides some reserve coolant to compensate for minor leaks and evaporation or boiling losses.

REMOVAL

Non - Turbo

(1) Disconnect overflow hose from coolant outlet connector (Fig. 11).

(2) Remove vent hose clip from stud on dash panel (Fig. 12).

(3) Disconnect the MAP sensor connector.

(4) Remove fasteners securing power steering fluid reservoir bracket to engine. Reposition reservoir.

(5) Remove coolant recovery container attaching fasteners (Fig. 12).

(6) Remove coolant recovery container.

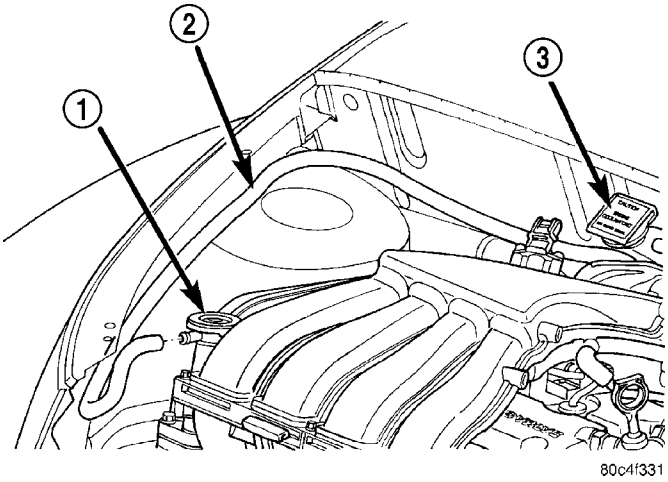

Fig. 11 Overflow Hose Routing

1 - OVERFLOW HOSE
2 - COOLANT OUTLET CONNECTOR

COOLANT RECOVERY CONTAINER (Continued)

(3) Remove lower screw securing coolant recovery container to dash panel (Fig. 14).

(4) Lower vehicle.

(5) Remove throttle cable shield from throttle body.

(6) Disconnect throttle and speed control cables from throttle body. Reposition cables.

(7) Remove nut securing coolant recovery container to dash panel (Fig. 14).

(8) Remove coolant recovery container.

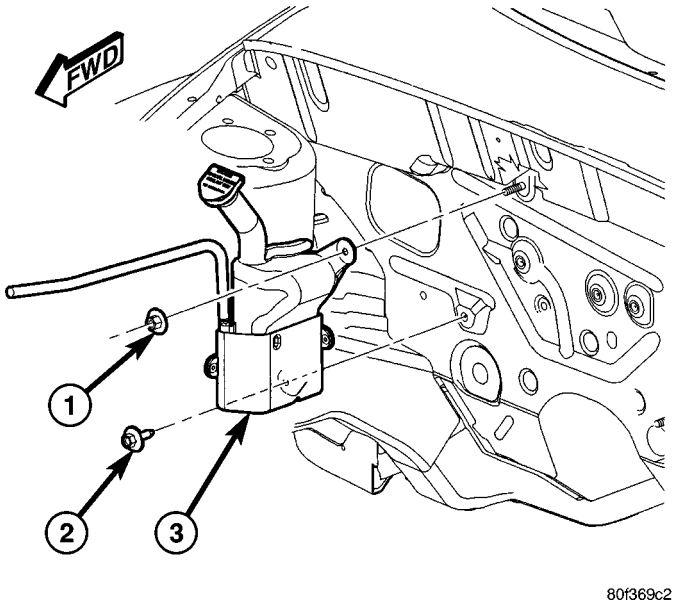

Fig. 14 Coolant Recovery Container - 2.4L Turbo

1 - NUT
2 - SCREW
3 - COOLANT RECOVERY CONTAINER

INSTALLATION

Non - Turbo

(1) Install coolant recovery container and tighten fasteners to 4 N·m (35 in. lbs.) (Fig. 12).

(2) To ensure proper vent hose routing, install vent hose clip on stud at dash panel (Fig. 12).

(3) Connect the MAP sensor connector.

(4) Position and install the power steering fluid reservoir bracket fasteners.

(5) Connect overflow hose to coolant outlet connector (Fig. 11).

(6) Fill container to proper level.

Turbo

(1) Install coolant recovery container and tighten fasteners to 4 N·m (35 in. lbs.) (Fig. 14).

(2) Connect throttle and speed control cables to throttle body.

(3) Install throttle cable shield to throttle body.

(4) Connect overflow hose to coolant outlet connector (Fig. 13).

(5) Fill container to proper level.

COOLING SYSTEM PRESSURE CAP

DESCRIPTION

The cooling system pressure cap (Fig. 15) is located on the coolant outlet connector near the front of the cylinder head. The pressure cap is constructed of stainless steel. Rubber seals provide sealing to the outlet connector and to the coolant recovery system. A calibrated spring located between the cap and the connector seal provides for cooling system pressure release.

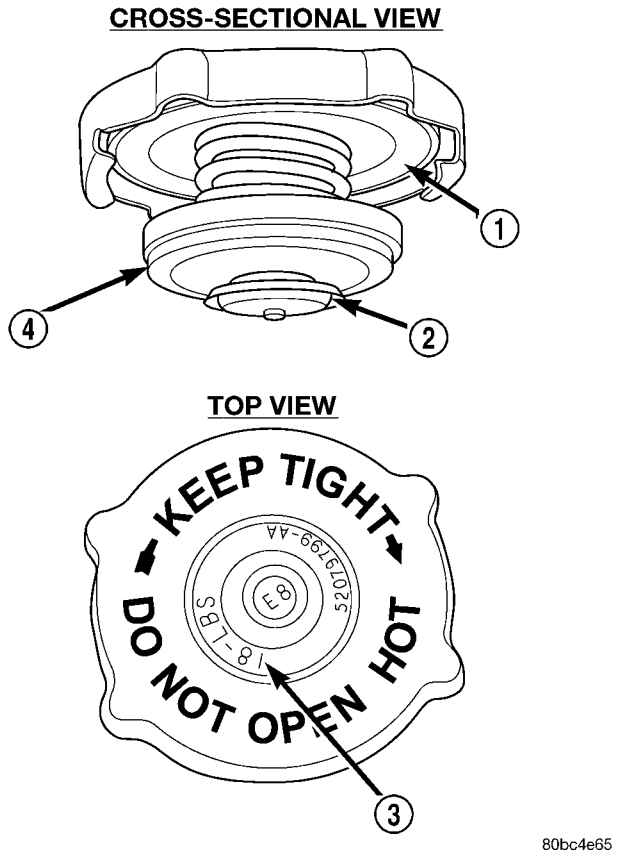

Fig. 15 Cooling System Pressure Cap

1 - FILLER NECK SEAL
2 - VACUUM VENT VALVE
3 - PRESSURE RATING
4 - PRESSURE VALVE

OPERATION

The pressure cap allows the cooling system to operate at higher than atmospheric pressure. The higher pressure raises the coolant boiling point, allowing increased radiator cooling capacity. The pressure cap

COOLING SYSTEM PRESSURE CAP (Continued)

will release cooling system pressure in a range of 97-124 kPa (14-18 psi).

A vent valve located in the center of the cap allows a coolant flow to and from the coolant recovery system bottle. This valve is spring loaded in the closed position. However, it must be free to open during system cool-down. **If the valve is stuck shut, the radiator hoses will collapse on cool-down. Clean the vent valve (Fig. 15) to ensure proper sealing function.**

A gasket in the pressure cap seals the top of the filler neck so that vacuum is maintained to draw coolant back into the system from the coolant recovery system bottle.

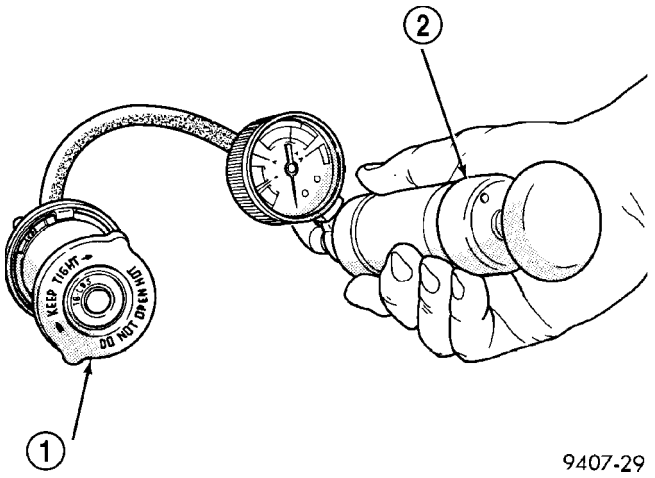

Fig. 16 Testing Cooling System Pressure Cap

1 - PRESSURE CAP
2 - PRESSURE TESTER

DIAGNOSIS AND TESTING

DIAGNOSIS AND TESTING - COOLING SYSTEM PRESSURE CAP TESTING

Dip the pressure cap in water. Clean any deposits off the vent valve or its seat and apply cap to end of the Pressure Cap Test Adaptor that is included with the Cooling System Tester 7700 (Fig. 16). Working the plunger, bring the pressure to 104 kPa (15 psi) on the gauge. If the pressure cap fails to hold pressure of at least 97 kPa (14 psi), replace the pressure cap.

CAUTION: The Cooling System Tester Tool is very sensitive to small air leaks that will not cause cooling system problems. A pressure cap that does not have a history of coolant loss should not be replaced just because it leaks slowly when tested with this tool. Add water to the tool. Turn tool upside down and recheck pressure cap to confirm that cap is bad.

If the pressure cap tests properly while positioned on Cooling System Tester (Fig. 16), but will not hold pressure or vacuum when positioned on the filler neck. Inspect the filler neck and cap top gasket for irregularities that may prevent the cap from sealing properly.

DIAGNOSIS AND TESTING - COOLING SYSTEM PRESSURE RELIEF TESTING

WARNING: THE WARNING WORDS "DO NOT OPEN HOT" ON THE PRESSURE CAP IS A SAFETY PRECAUTION. WHEN HOT, THE COOLING SYSTEM BUILDS UP PRESSURE. TO PREVENT SCALDING OR OTHER INJURY, THE PRESSURE CAP SHOULD NOT BE REMOVED WHILE THE SYSTEM IS HOT AND/OR UNDER PRESSURE.

The pressure cap upper gasket to filler neck seal can be checked by removing the overflow hose at the filler neck overflow nipple (Fig. 17). Attach the radiator pressure tester to the **filler neck overflow nipple,** and pump air into the system. The pressure cap upper gasket should relieve pressure at 69-124 kPa (10-18 psi), and hold pressure at 55 kPa (8 psi) minimum.

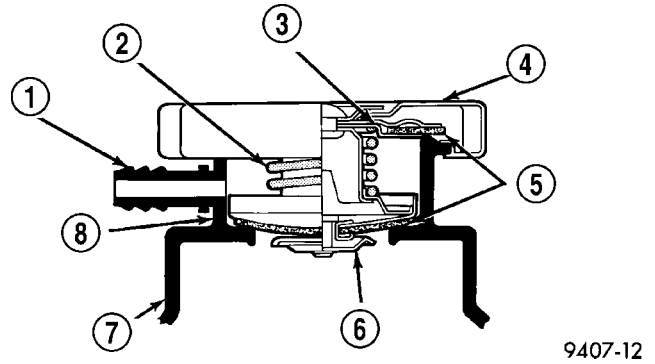

Fig. 17 Cooling System Pressure Cap to Filler Neck

2 - MAIN SPRING
3 - GASKET RETAINER
4 - STAINLESS-STEEL SWIVEL TOP
5 - RUBBER SEALS
6 - VENT VALVE
7 - THERMOSTAT HOUSING/ENGINE OUTLET CONNECTOR
8 - FILLER NECK

There is no need to remove the pressure cap at any time **except** for the following purposes:

- Check and adjust coolant freeze point
- Refill system with new coolant
- Conducting service procedures
- Checking for leaks

COOLING SYSTEM PRESSURE CAP (Continued)

WARNING: IF VEHICLE HAS BEEN RUN RECENTLY, WAIT 15 MINUTES BEFORE REMOVING CAP. PLACE A SHOP TOWEL OVER THE CAP, AND WITHOUT PUSHING DOWN, ROTATE IT COUNTERCLOCKWISE TO THE FIRST STOP. ALLOW FLUIDS TO ESCAPE THROUGH THE OVERFLOW TUBE. WHEN THE SYSTEM STOPS PUSHING COOLANT AND STEAM INTO THE CRS TANK AND PRESSURE DROPS, PUSH DOWN ON THE CAP AND REMOVE IT COMPLETELY. SQUEEZING THE RADIATOR INLET HOSE WITH A SHOP TOWEL (TO CHECK PRESSURE) BEFORE AND AFTER TURNING TO THE FIRST STOP IS RECOMMENDED.

CLEANING

Use only a mild soap to clean the pressure cap.

INSPECTION

Hold the cap in your hand, **right side up** (Fig. 18). The vent valve at the bottom of the cap should open with a slight pull. If the rubber gasket has swollen, preventing the valve from opening, replace the cap.

If any light can be seen between vent valve and the rubber gasket, replace the cap. **Use only a replacement cap that has a spring to hold the vent shut.**

A replacement cap must be of the type designed for coolant reserve systems. This design ensures system pressurization.

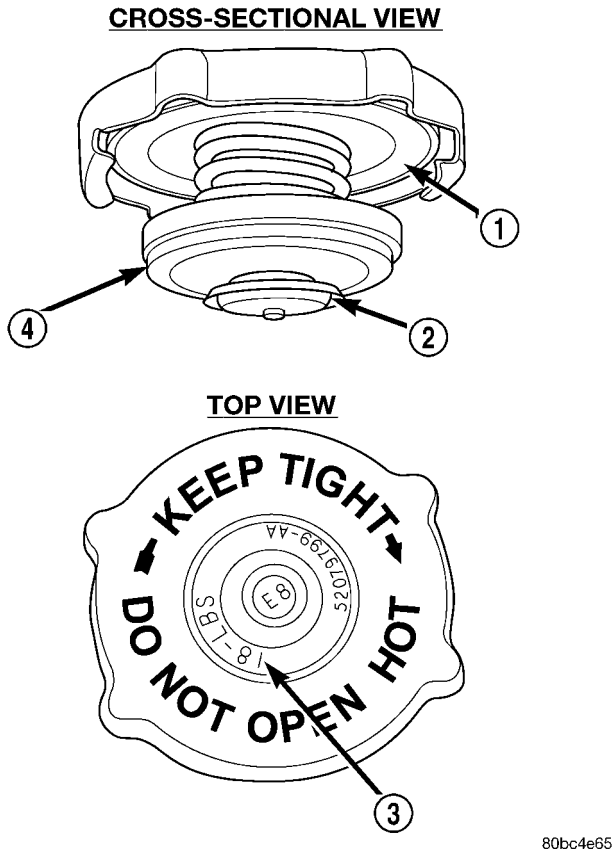

Fig. 18 Cooling System Pressure Cap - Typical

2 - VACUUM VENT VALVE
3 - PRESSURE RATING
4 - PRESSURE VALVE

ENGINE BLOCK HEATER

DESCRIPTION

The heater is mounted in a core hole (in place of a core hole plug) in the engine block, with the heating element immersed in coolant (Fig. 19). The engine block heater is available as an optional accessory. The heater is powered by ordinary house current (110 Volt AC) through a power cord and connector (Fig. 20).

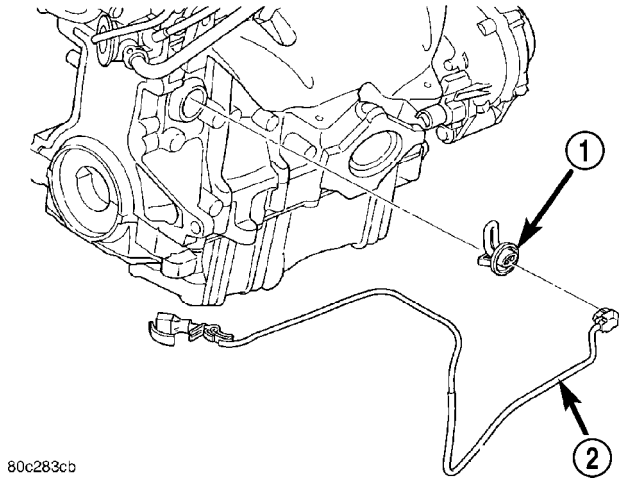

Fig. 19 Engine Block Heater

1 - BLOCK HEATER
2 - POWER CORD

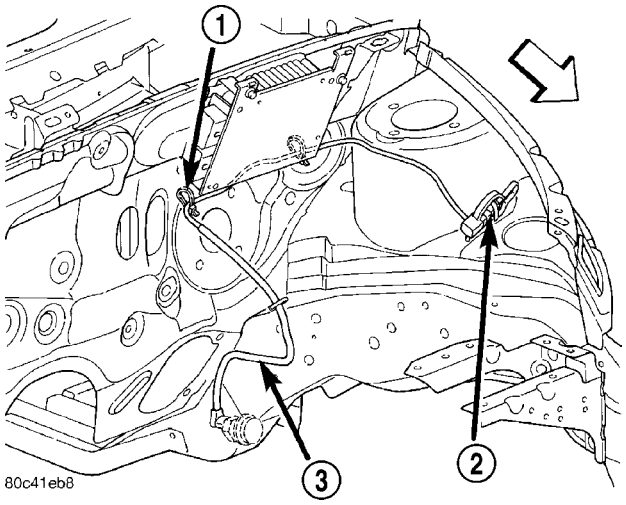

Fig. 20 Power Cord

1 - STRAP
2 - CONNECTOR
3 - POWER CORD

ENGINE BLOCK HEATER (Continued)

OPERATION

When in operation, the engine block heater can provide easier engine starting and faster warm-up, when vehicle is operated in areas having extremely low temperatures.

CAUTION: The power cord must be secured in its retainer clips, and not positioned so it could contact linkages or exhaust manifolds and become damaged.

DIAGNOSIS AND TESTING

ENGINE BLOCK HEATER

If heater unit does not operate (Fig. 19), possible causes can be either the power cord or the heater element. Test the power cord for continuity with a 110-volt voltmeter or 110-volt test light. Test heater element continuity with an ohmmeter or a 12-volt test light.

CAUTION: To prevent damage, the power cord (Fig. 20)must be secured in its retainer clips and away from any components that may cause abrasion or damage, such as linkages, exhaust components, etc.

REMOVAL

(1) Drain the cooling system (Refer to 7 - COOLING/ENGINE - STANDARD PROCEDURE - DRAINING COOLING SYSTEM).

(2) Detach power cord plug from heater (Fig. 19).

(3) Loosen screw in center of heater. Remove heater assembly (Fig. 19).

(4) If required, remove power cord (Fig. 20).

INSTALLATION

(1) Thoroughly clean core hole and heater seat.

(2) Insert heater assembly with element loop positioned **upward (Fig. 19)**.

(3) With heater seated, tighten center screw securely to assure a positive seal.

(4) If removed, install power cord (Fig. 20).

NOTE: Ensure power cord is properly routed and secured with straps.

(5) Connect power cord to block heater (Fig. 19).

(6) Fill cooling system (Refer to 7 - COOLING/ENGINE - STANDARD PROCEDURE - FILLING COOLING SYSTEM).

ENGINE COOLANT TEMPERATURE SENSOR

DESCRIPTION

The engine coolant temperature (ECT) sensor threads into the thermostat housing just below the coolant outlet connector (Fig. 21) or (Fig. 22). New sensors have sealant applied to the threads.

The ECT Sensor is a Negative Thermal Coefficient (NTC) Sensor. The resistance of the ECT Sensor changes as coolant temperature changes. This results in different input voltages to the PCM. The PCM also uses the ECT Sensor input to operate the radiator cooling fan(s), and send a message over the PCI bus to the instrument cluster for temperature gauge operation.

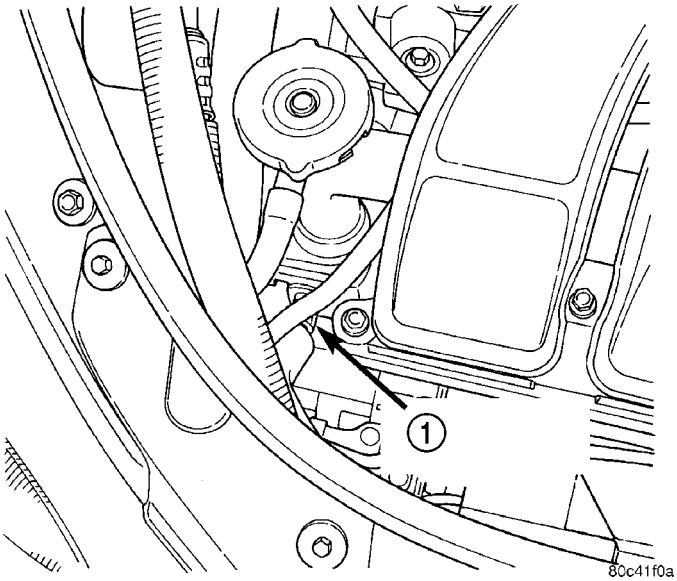

Fig. 21 Engine Coolant Temperature Sensor

1 - ENGINE COOLANT TEMPERATURE SENSOR

OPERATION

The ECT sensor provides an input to the PCM. As temperature increases, resistance of the sensor decreases. As coolant temperature varies, the ECT sensor resistance changes resulting in a different voltage value at the PCM ECT sensor signal circuit. The ECT sensor provides input for various PCM operations. The PCM uses the input to control air-fuel mixture, timing, and radiator fan on/off times. The PCM uses ECT sensor input to send messages over the PCI bus for temperature gauge operation.

ENGINE COOLANT TEMPERATURE SENSOR (Continued)

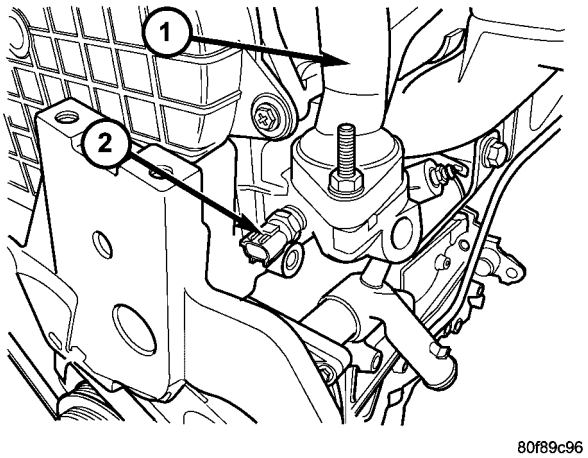

Fig. 22 Engine Coolant Temperature Sensor - 2.4L Turbo

1 - COOLANT OUTLET CONNECTOR
2 - ENGINE COOLANT TEMPERATURE SENSOR

REMOVAL

Non-Turbo

(1) Disconnect negative battery cable.
(2) Partially drain cooling system below level of ECT Sensor.
(3) Disconnect ECT Sensor electrical connector.
(4) Remove ECT Sensor (Fig. 21).

Turbo

(1) Disconnect negative battery cable.
(2) Partially drain cooling system below level of ECT Sensor.
(3) Remove upper torque strut (Refer to 9 - ENGINE/ENGINE MOUNTING/TORQUE STRUT - REMOVAL).
(4) Disconnect ECT Sensor electrical connector.
(5) Remove ECT Sensor (Fig. 22).

INSTALLATION

Non-Turbo

(1) Install ECT Sensor (Fig. 21). Torque sensor to 19 N·m (168 in. lbs.).
(2) Reconnect ECT Sensor electrical connector.
(3) Fill cooling system (Refer to 7 - COOLING/ENGINE - STANDARD PROCEDURE).
(4) Connect negative battery cable.

Turbo

(1) Install ECT Sensor (Fig. 22). Torque sensor to 19 N·m (168 in. lbs.).
(2) Reconnect ECT Sensor electrical connector.
(3) Install upper torque strut (Refer to 9 - ENGINE/ENGINE MOUNTING/TORQUE STRUT - INSTALLATION).
(4) Fill cooling system (Refer to 7 - COOLING/ENGINE - STANDARD PROCEDURE).
(5) Connect negative battery cable.

ENGINE COOLANT THERMOSTAT

DESCRIPTION

The thermostat is located on the front of the engine (radiator side) in the thermostat housing/coolant outlet connector (Fig. 23). The thermostat has an air bleed vent located on its flange (Fig. 24). The air bleed vent and the locator dimple on thermostat seal provide for proper positioning of thermostat in outlet connector. A cooling system air bleed valve is located in thermostat housing to assist in air removal when filling the cooling system.

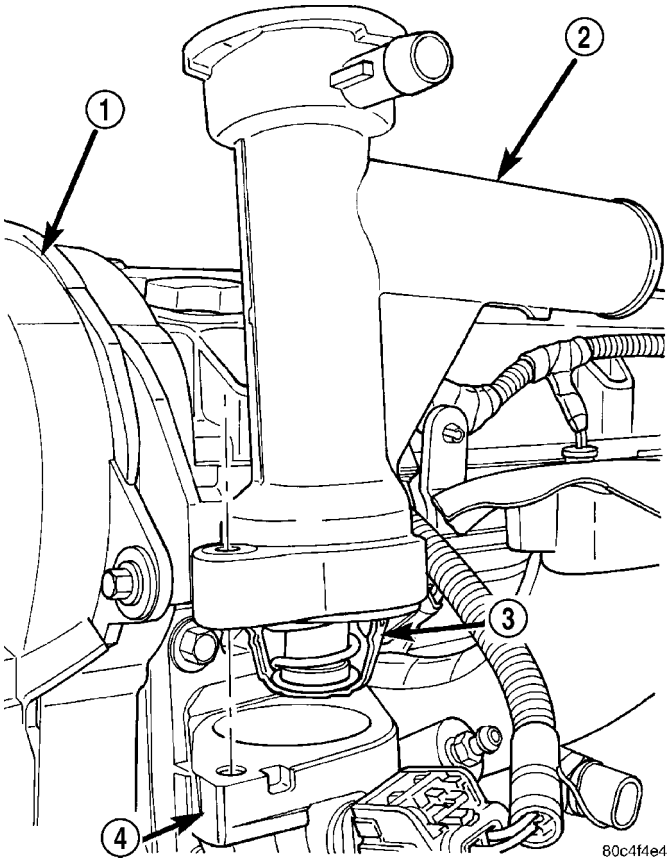

Fig. 23 Thermostat and Coolant Outlet Connector

1 - TIMING BELT COVER

3 - THERMOSTAT
4 - HOUSING

ENGINE COOLANT THERMOSTAT (Continued)

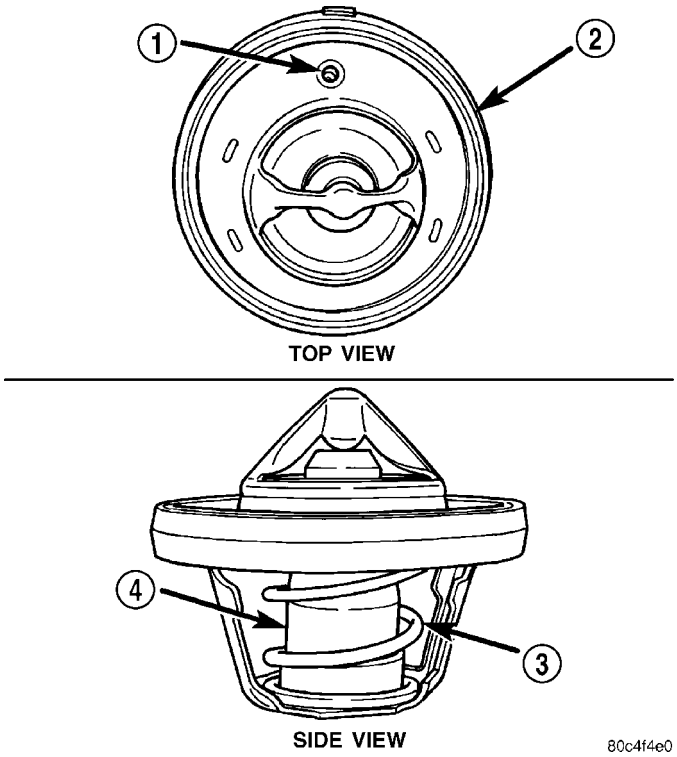

Fig. 24 Thermostat

1 - AIR BLEED
2 - SEAL
3 - RETURN SPRING
4 - PELLET CHAMBER

OPERATION

The engine cooling thermostat is a wax pellet driven, reverse poppet choke type. The thermostat is designed to provide the fastest warm up possible by preventing leakage through it and to guarantee a minimum engine operating temperature of 88 to 93°C (192 to 199°F). The thermostat will also automatically reach wide open so it will not restrict flow to the radiator as the temperature of the coolant rises in hot weather to around 104°C (220°F). Above this temperature the coolant temperature is controlled by the radiator, fan, and ambient temperature, not the thermostat.

The thermostat is operated by a wax filled chamber (pellet) which is sealed (Fig. 24). When coolant reaches a predetermined temperature, the wax expands enough to overcome the closing spring (Fig. 24) and water pump pressure, which forces the thermostat to open. Coolant leakage into the wax pellet will cause a thermostat to fail in the open position. Do not attempt to free-up a stuck open thermostat.

If the thermostat is stuck open or allows coolant leakage through it, the engine will not operate at the proper temperature for obtaining engine fuel efficiency, performance and emissions levels. If this condition occurs, a diagnostic trouble code will be set and a MIL light will be turned on. Refer to the Powertrain Diagnostic Procedures manual for further information and diagnostics provided.

DIAGNOSIS AND TESTING - ENGINE COOLANT THERMOSTAT

The thermostat is operated by a wax filled chamber (pellet) which is sealed. When heated coolant reaches a predetermined temperature the wax pellet expands enough to overcome the closing spring and water pump pressure, which forces the valve to open. Coolant leakage into the pellet will cause a thermostat to fail open. Do not attempt to free up a thermostat with a screwdriver.

Thermostat diagnostics is included in powertrain control module's (PCM) programing for on-board diagnosis. The malfunction indicator light (MIL) will illuminate and a diagnostic trouble code (DTC) will be set when an “open too soon” condition occurs. Do not change a thermostat for lack of heater performance or temperature gauge position, unless a DTC is present. For other probable causes, (Refer to 7 - COOLING/ENGINE - DIAGNOSIS AND TESTING). Thermostat failing shut is the normal long term mode of failure, and normally, only on high mileage vehicles. The temperature gauge will indicate this (Refer to 7 - COOLING/ENGINE - DIAGNOSIS AND TESTING).

REMOVAL

(1) Remove upper intake manifold (Refer to 9 - ENGINE/MANIFOLDS/INTAKE MANIFOLD - REMOVAL).

(2) Partially drain cooling system below the thermostat level.

(3) Disconnect upper radiator hose from outlet connector.

(4) Disconnect coolant recovery system hose from outlet connector.

(5) **Turbocharger equipped vehicles:**

- Remove fastener securing A/C suction line support bracket to coolant oulet connector stud.
- Unclip A/C suction line support bracket from A/C suction line. Reposition bracket.

(6) Remove coolant outlet connector bolts (Fig. 23).

(7) Remove thermostat assembly, and clean sealing surfaces.

ENGINE COOLANT THERMOSTAT (Continued)

INSTALLATION

(1) Place the new thermostat assembly into the coolant outlet connector, aligning air bleed with the location notch on outlet connector (Fig. 25).

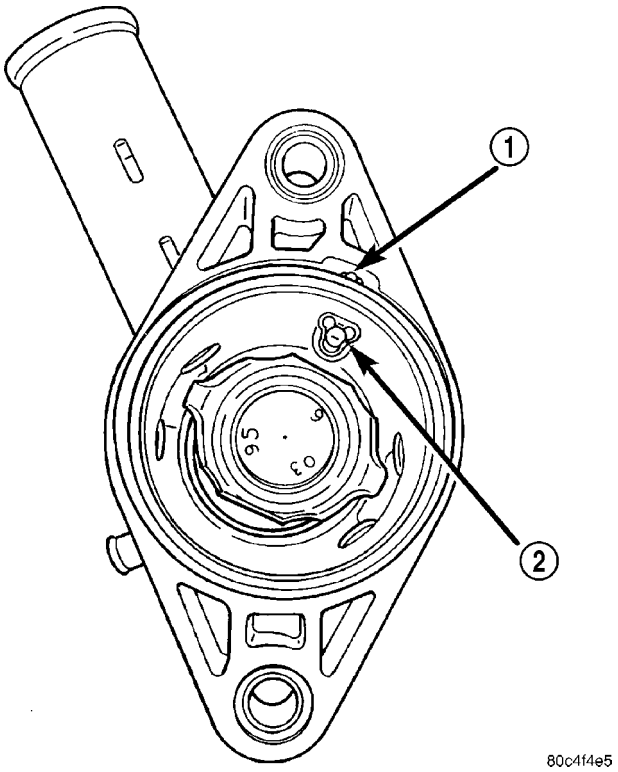

Fig. 25 Thermostat Position

1 - LOCATOR NOTCH
2 - AIR BLEED

(2) Install coolant outlet connector with thermostat in position onto thermostat housing (Fig. 23). Tighten bolts to 12.5 N·m (110 in. lbs.).

(3) **Turbocharger equipped vehicles:**

- Attach A/C suction line support bracket to A/C suction line.
- Install fastener securing A/C suction line support bracket to coolant oulet connector.

(4) Connect upper radiator hose.

(5) Connect the coolant recovery system hose.

(6) Install upper intake manifold (Refer to 9 - ENGINE/MANIFOLDS/INTAKE MANIFOLD - INSTALLATION).

(7) Fill cooling system (Refer to 7 - COOLING/ENGINE - STANDARD PROCEDURE).

HOSE CLAMPS

DESCRIPTION - HOSE CLAMPS

The cooling system utilizes both worm drive and spring type hose clamps. If a spring type clamp replacement is necessary, replace with the original Mopar® equipment spring type clamp.

CAUTION: A number or letter is stamped into the tongue of constant tension clamps. If replacement is necessary, use only a original equipment clamp with matching number or letter (Fig. 26).

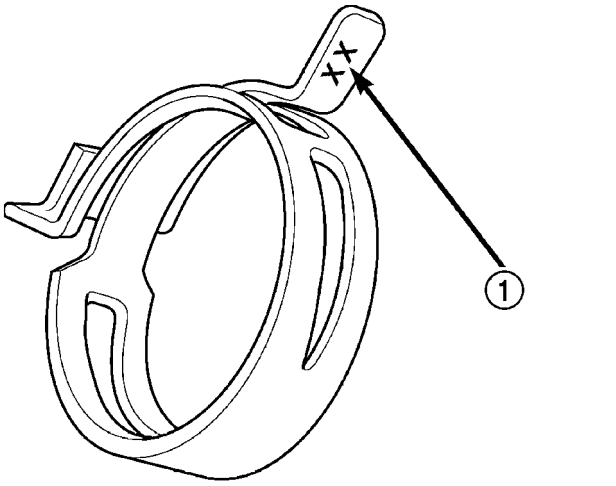

Fig. 26 Spring Clamp Size Location

1 - SPRING CLAMP SIZE LOCATION

OPERATION

The worm type hose clamp uses a specified torque value to maintain proper tension on a hose connection.

The spring type hose clamp applies constant tension on a hose connection. To remove a spring type hose clamp, only use constant tension clamp pliers (Special Tool 8495) designed to compress the hose clamp. For Special Tool Identification, (Refer to 7 - COOLING - SPECIAL TOOLS).

RADIATOR FAN

DESCRIPTION

Non-Turbo

The radiator cooling fan is a dual-speed electric motor driven fan. The radiator fan assembly includes an electric motor, fan blade, and a support shroud that is attached to the radiator (Fig. 31). The radiator fan is serviced as an assembly (fan motor/fan/shroud).

Turbo

The radiator cooling fan is a variable speed electric motor driven fan. The radiator fan assembly includes an electric motor, fan blade, and a support shroud that is attached to the radiator (Fig. 32). The radiator fan is serviced as an assembly (fan motor/fan/shroud).

RADIATOR FAN (Continued)

OPERATION

Non-Turbo

Radiator fan operation is control by the Powertrain Control Module (PCM) with inputs from the temperature of the coolant, which is sensed by the coolant temperature sensor, and vehicle speed which is measured by the vehicle speed sensor. The PCM turns on the fan through either the high or low speed fan relay. The PCM provides a ground to the relay's control circuit. The fan relays are located in the Power Distribution Center (PDC) (Fig. 27). Refer to the label beneath the PDC cover for location of fan relays.

Refer to **Radiator Fan Operation Chart** for fan operation specifications. For fan circuit wiring diagrams, refer to WIRING DIAGRAMS.

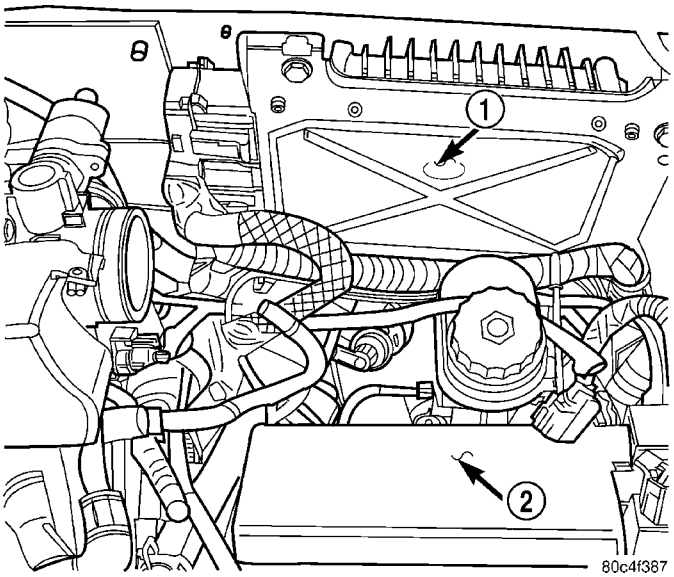

Fig. 27 Power Distribution Center (PDC)

1 - PCM
2 - PDC

If the cooling fan is inoperative or a Diagnostic Trouble Code (DTC) related to fan control has been set, refer to the appropriate Powertrain Diagnostic Information for diagnostic procedures.

RADIATOR FAN OPERATION CHART

Radiator Fan Control		
	Low Speed	**High Speed**
A/C Off –vehicle speed < 70.8 km/h (44 mph)		
Fan On:	96.6° C (206° F)	103° C (219° F)
Fan Off:	92.7° C (199° F)	98.8° C (210° F)
A/C Off –vehicle speed > 70.8 km/h (44 mph) (until vehicle speed drops below 58 km/h (36 mph)		
Fan On:	Off	103° C (219° F)
Fan Off:		98.8° C (210° F)
A/C On –any vehicle speed		
Fan On:	Off	82.2° C (180° F)
Fan Off:		80° C (176° F)

Turbo

The variable speed radiator fan is controlled by the Powertrain Control Module (PCM) by way of a Pulse Width Modulated (PWM) signal. The duty cycle ranges from 30% for low speed operation, then ramps-up to 100% for high speed operation. This fan control system provides infinitely variable fan speeds, allowing for improved fan noise, A/C performance, better engine cooling, and additional vehicle power.

To control radiator fan operation, the PCM looks at inputs from:

- Engine coolant temperature
- A/C pressure transducer
- Ambient temperature
- Vehicle speed
- Transmission oil temperature (automatic transmission only)

The PCM uses these inputs to determine when the fan should operate and at what speed.

RADIATOR FAN (Continued)

DIAGNOSIS AND TESTING

RADIATOR FAN MOTOR TEST

Refer to Powertrain Diagnostic Manual for procedure.

REMOVAL

NOTE: The fan motor, fan, and the shroud are serviced as an assembly.

WARNING: DO NOT OPEN THE RADIATOR DRAINCOCK WITH THE SYSTEM HOT AND UNDER PRESSURE BECAUSE SERIOUS BURNS FROM COOLANT CAN OCCUR.

(1) Disconnect negative cable from battery.

(2) Remove battery and battery tray (Refer to 8 - ELECTRICAL/BATTERY SYSTEM/BATTERY - REMOVAL).

(3) Drain cooling system below upper radiator hose level (Refer to 7 - COOLING/ENGINE - STANDARD PROCEDURE).

(4) Remove grille (Refer to 23 - BODY/EXTERIOR/GRILLE - REMOVAL).

(5) Remove upper radiator closure panel and center brace (Refer to 23 - BODY/EXTERIOR/RADIATOR CLOSURE PANEL - REMOVAL) (Fig. 28).

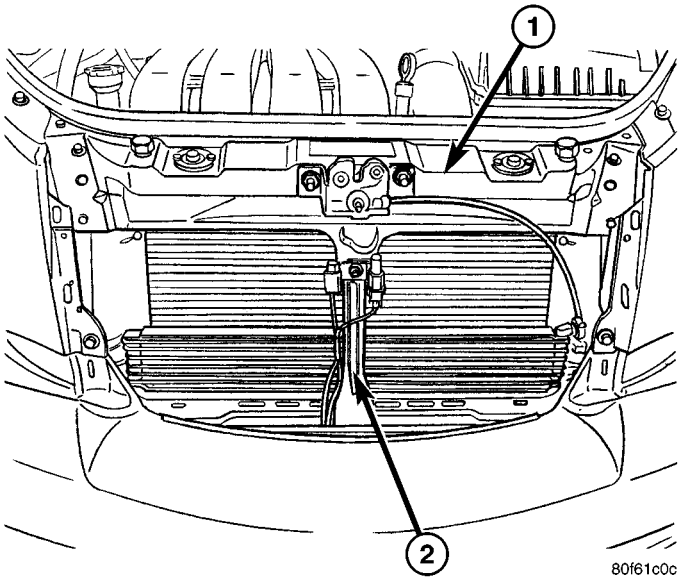

Fig. 28 Upper Radiator Closure Panel and Center Brace

1 - UPPER RADIATOR CLOSURE PANEL
2 - CENTER BRACE

(6) Disconnect upper radiator hose from radiator.

(7) **Turbocharger equipped vehicles:** Remove radiator inlet neck (Fig. 29).

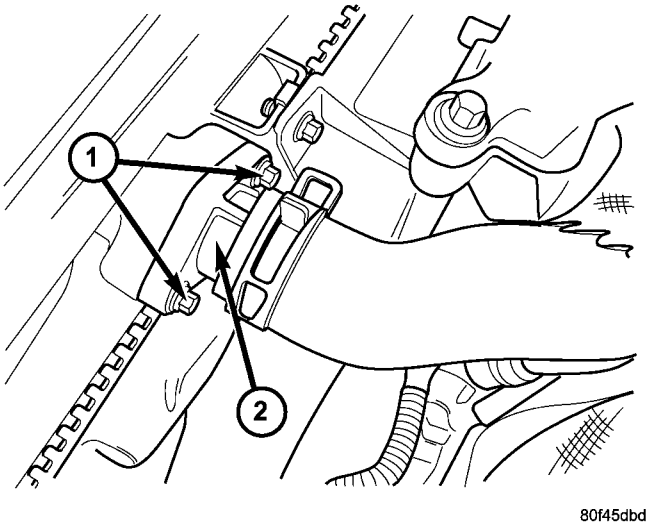

Fig. 29 Radiator Inlet Neck - 2.4L Turbo

1 - FASTENERS
2 - RADIATOR INLET NECK

(8) Hoist vehicle.

(9) Disconnect radiator fan electrical connector (Fig. 30).

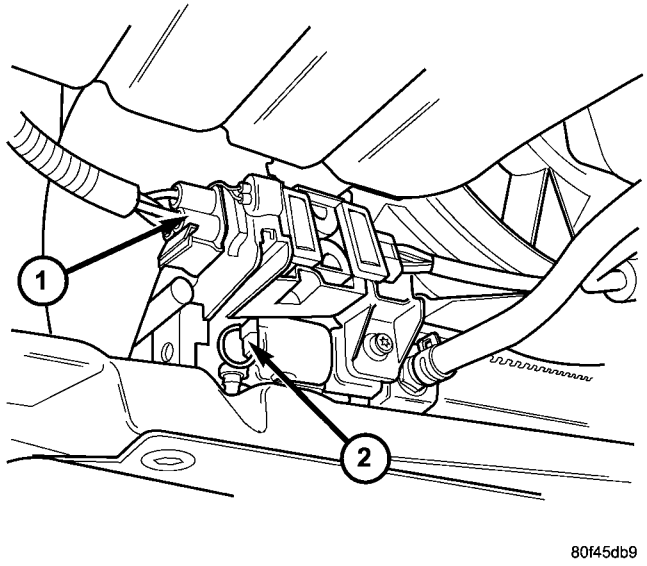

Fig. 30 Radiator Fan Connector - 2.4L Turbo

1 - RADIATOR FAN CONNECTOR
2 - RADIATOR DRAINCOCK

(10) Remove the two lower and left side radiator fan screws (Fig. 31) and (Fig. 32).

(11) Lower vehicle and remove the remaining radiator fan attaching screws.

CAUTION: Care should be taken not to damage the radiator cooling fins and tubes during fan removal.

RADIATOR FAN (Continued)

(12) Remove radiator fan by lifting up from the engine compartment.

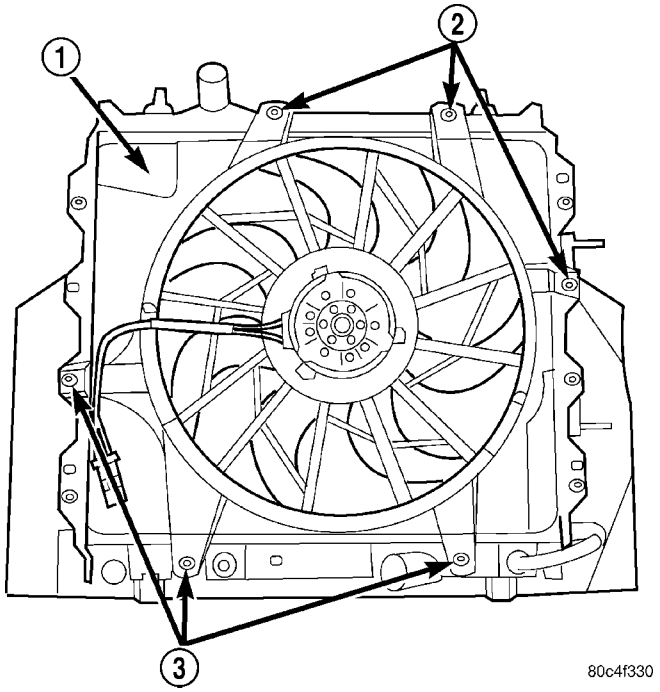

Fig. 31 Radiator Fan - Mounting

1 - RADIATOR FAN SHROUD
2 - SCREWS
3 - SCREWS

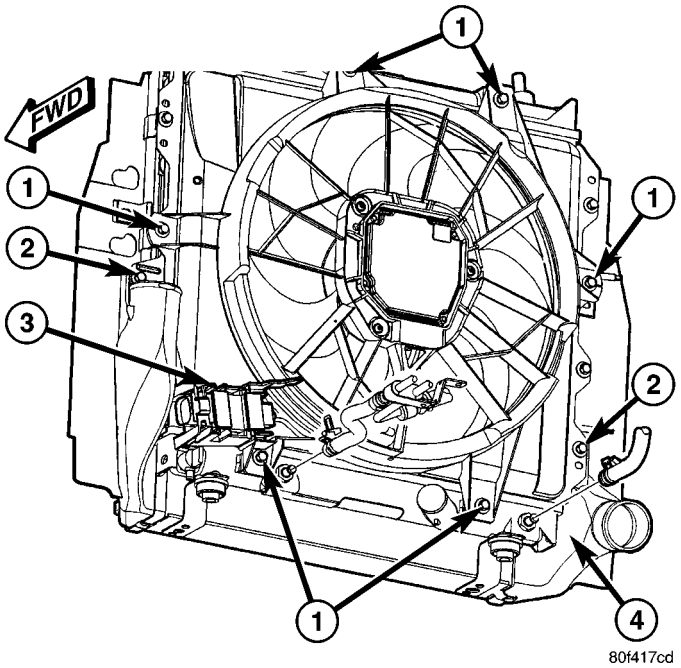

Fig. 32 Cooling Module - 2.4L Turbo

1 - RADIATOR FAN FASTENERS
2 - CHARGE AIR COOLER FASTENERS
3 - RADIATOR FAN CONNECTOR
4 - CHARGE AIR COOLER

INSTALLATION

(1) Install the radiator fan into position on the radiator.

(2) Hand start all radiator fan fasteners.

(3) Tighten all radiator fan retaining screws to 6 N·m (55 in. lbs.) (Fig. 31) and (Fig. 32).

(4) Connect radiator fan electrical connector (Fig. 30).

(5) Lower vehicle.

(6) **Turbocharger equipped vehicles:** Inspect radiator inlet neck o-ring. Replace if necessary. Install radiator inlet neck (Fig. 29). Torque fasteners to 6 N·m (55 in. lbs.).

(7) Connect the upper radiator hose to radiator. Align hose and position clamp so it will not interfere with the engine or the hood.

(8) Install upper radiator closure panel and center brace (Refer to 23 - BODY/EXTERIOR/RADIATOR CLOSURE PANEL - INSTALLATION) (Fig. 28).

(9) Install grille (Refer to 23 - BODY/EXTERIOR/GRILLE - INSTALLATION).

(10) Install battery tray and battery.

(11) Connect cables to battery.

(12) Fill cooling system (Refer to 7 - COOLING/ENGINE - STANDARD PROCEDURE).

RADIATOR

REMOVAL

WARNING: DO NOT OPEN THE RADIATOR DRAIN-COCK WITH THE SYSTEM HOT AND UNDER PRESSURE BECAUSE SERIOUS BURNS FROM COOLANT CAN OCCUR.

NOTE: It is not necessary to discharge the air conditioning system to remove the radiator.

(1) Drain cooling system (Refer to 7 - COOLING/ENGINE - STANDARD PROCEDURE).

(2) Remove radiator fan (Refer to 7 - COOLING/ENGINE/RADIATOR FAN - REMOVAL).

(3) **Turbocharger Equipped Vehicles:** Disconnect and cap the power steering hoses.

(4) Disconnect lower radiator hose (Fig. 33).

(5) **Non-Turbo Vehicles with Automatic Transmission:** Remove two fasteners attaching transmission oil cooler to radiator.

(6) **Non-Turbo Vehicles:** Dislodge lower radiator air seal from side radiator air seals (Fig. 34).

(7) Remove fasteners attaching AC condenser to radiator. Reposition AC condenser.

(8) **Turbocharger Equipped Vehicles:** Remove fasteners attaching charge air cooler to radiator (Fig. 35).

RADIATOR (Continued)

(9) Remove radiator assembly (Fig. 36) by lifting it up from the engine compartment. **Care should be taken not to damage the cooling fins and tubes during removal.**

(10) **Non-Turbo Vehicles:** Remove the lower air seal from radiator (Fig. 34).

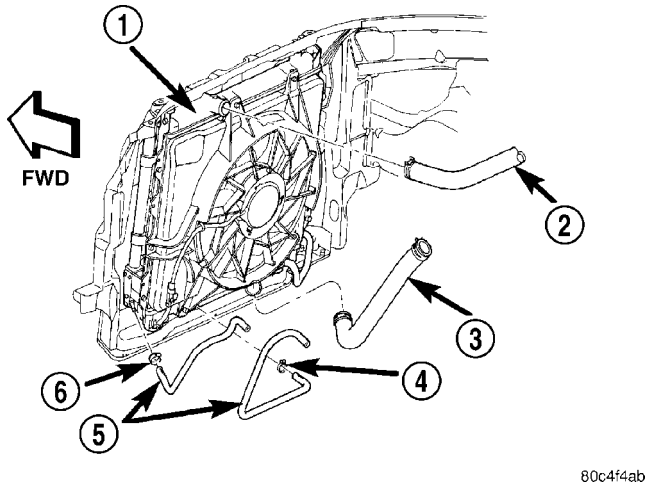

Fig. 33 Radiator Hose Connections

4 - CLAMP
5 - TRANSMISSION OIL COOLER HOSES
6 - CLAMP

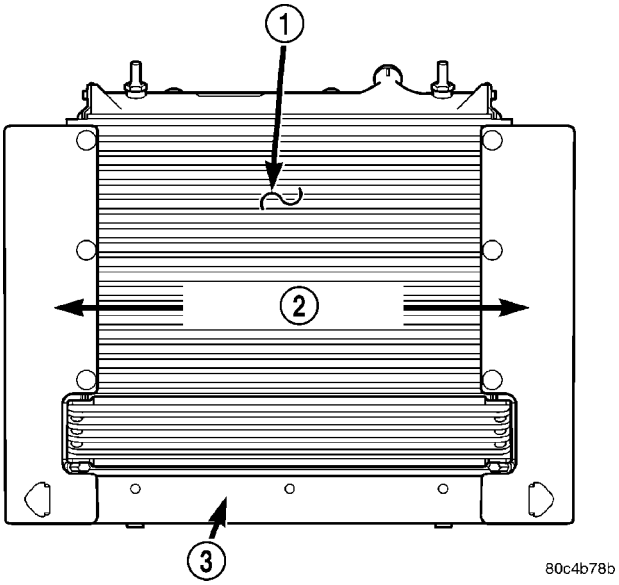

Fig. 34 Air Seals

1 - A/C CONDENSER
2 - SIDE AIR SEALS
3 - LOWER AIR SEAL

CLEANING

Clean radiator fins are necessary for good heat transfer. The radiator and air conditioning fins should be cleaned when an accumulation of debris has occurred. With the engine cold, apply cold water and compressed air to the back (engine side) of the radiator to flush the radiator and/or A/C condenser of debris.

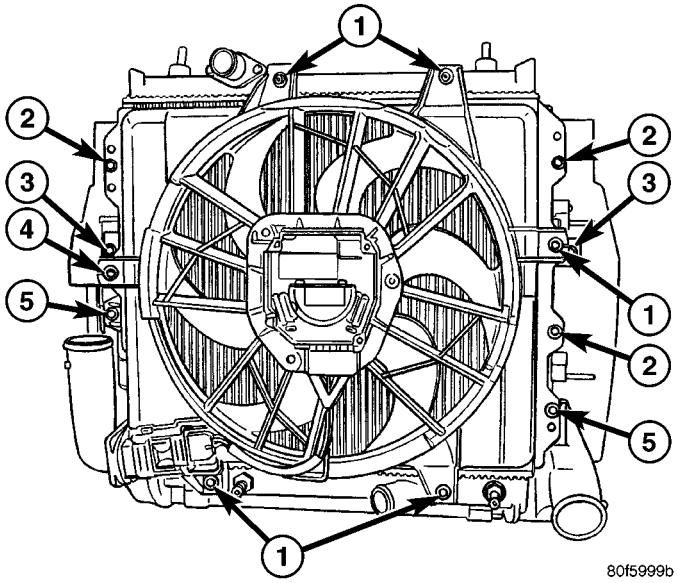

Fig. 35 Cooling Module Fasteners - 2.4L Turbo

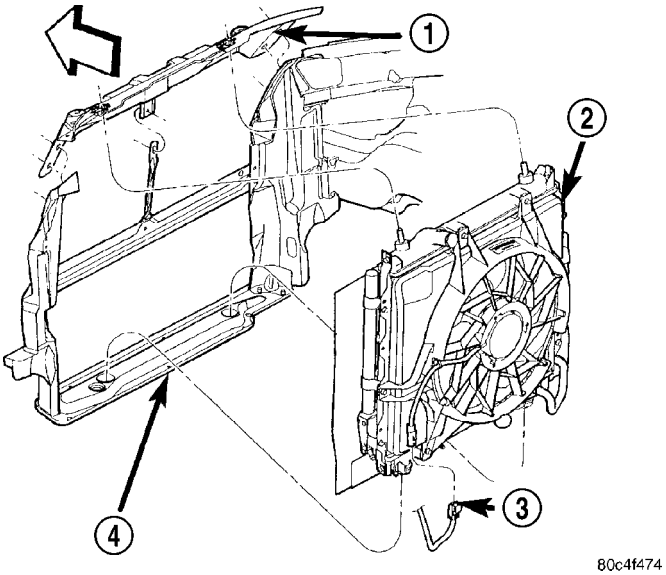

Fig. 36 Cooling Module Assembly

1 - UPPER RADIATOR CLOSURE PANEL
2 - COOLING MODULE
3 - RADIATOR FAN CONNECTOR
4 - LOWER RADIATOR CROSSMEMBER

RADIATOR (Continued)

INSPECTION

Inspect the radiator tanks for cracks, broken or missing fittings also inspect the joint where the tanks seam up to the radiator core for signs of leakage and/or deteriorating seals.

Inspect radiator core for corroded, bent or missing cooling fins. Inspect the core for bent or damaged cooling tubes.

INSTALLATION

(1) **Non-Turbo Vehicles:** Install the lower air seal to radiator (Fig. 34).

NOTE: Turbocharger Equipped Vehicles: When lowering radiator, make sure lower radiator pins engage properly through charge air cooler locating tabs (Fig. 37).

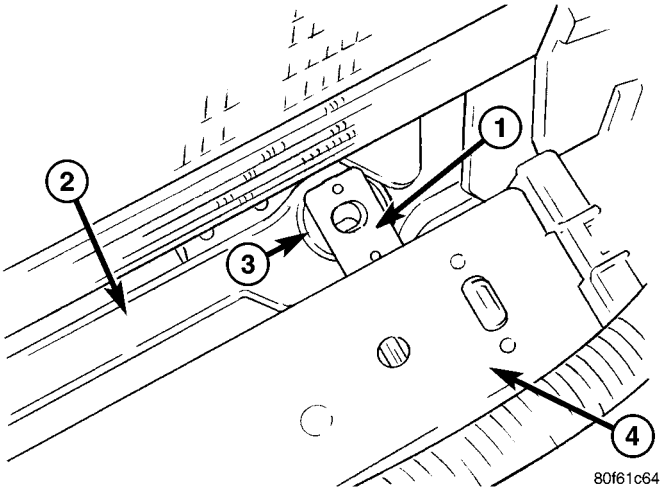

Fig. 37 Charge Air Cooler Locating Tab

1 - LOCATING TAB
2 - LOWER RADIATOR SUPPORT CROSSMEMBER
3 - RADIATOR MOUNT BUSHING
4 - CHARGE AIR COOLER

(2) Position radiator into mounting position.

(3) Position A/C condenser against radiator. Hand start fasteners.

(4) **Turbocharger Equipped Vehicles:** Install fasteners attaching charge air cooler to radiator. Torque fasteners to 8 N·m (70 in. lbs.) (Fig. 35).

(5) Install radiator fan/shroud assembly. Hand start fasteners.

(6) Torque all condenser fasteners to 8 N·m (70 in. lbs.).

(7) Torque all radiator fan fasteners to 6 N·m (55 in. lbs.).

(8) **Non-Turbo Vehicles with Automatic Transmission:** Install fasteners attaching transmission oil cooler to radiator. Torque fasteners to 8 N·m (70 in. lbs.).

(9) Raise vehicle on hoist.

(10) **Non-Turbo Vehicles:** Connect the lower air seal to the side air seals (Fig. 34).

(11) Connect lower radiator hose (Fig. 33). Align the hose and position the clamp so it will not interfere with engine components.

(12) Connect the radiator fan electrical connector.

(13) **Turbocharger Equipped Vehicles:** Connect the power steering hoses.

(14) Close radiator draincock.

(15) Lower vehicle.

(16) **Turbocharger equipped vehicles:** Inspect radiator inlet neck o-ring. Replace if necessary. Install radiator inlet neck. Torque fasteners to 6 N·m (55 in. lbs.).

(17) Connect upper radiator hose (Fig. 33). Align the hose and position the clamp to prevent interference with the engine or hood.

(18) Install upper radiator closure panel and center brace (Refer to 23 - BODY/EXTERIOR/RADIATOR CLOSURE PANEL - INSTALLATION).

(19) Install grille (Refer to 23 - BODY/EXTERIOR/GRILLE - INSTALLATION).

(20) Install battery tray and battery.

(21) Connect positive battery cable. Connect negative battery cable.

(22) Install air cleaner housing assembly.

(23) Fill cooling system with coolant (Refer to 7 - COOLING/ENGINE - STANDARD PROCEDURE).

(24) Operate engine until it reaches normal operating temperature. Check cooling system for correct fluid level.

(25) **Turbocharger Equipped Vehicles:** Check power steering fluid level. Fill as needed.

RADIATOR DRAINCOCK

REMOVAL

CAUTION: Use of pliers on draincock is not recommended. Damage may occur to radiator or draincock.

NOTE: It is not necessary to remove draincock during a routine coolant drain.

(1) Drain the cooling system (Refer to 7 - COOLING/ENGINE - STANDARD PROCEDURE).
(2) Open the draincock by turning it counterclockwise until it stops.
(3) Turn the draincock back (clockwise) 1/8 turn.
(4) Pull the draincock (Fig. 38) from the radiator tank.

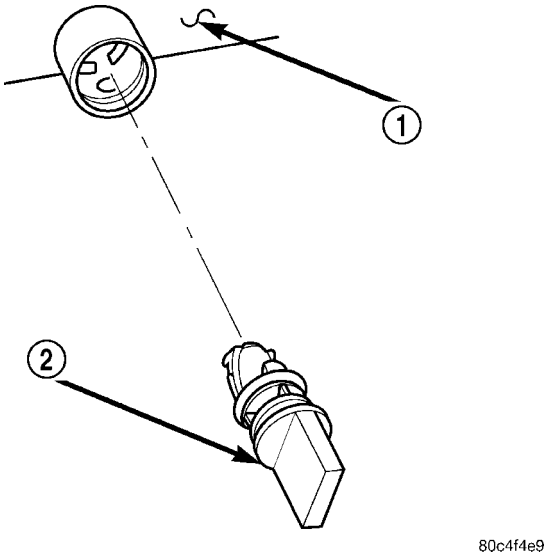

Fig. 38 Draincock

1 - RADIATOR TANK
2 - DRAINCOCK

INSTALLATION

(1) Align draincock stem to radiator tank opening.
(2) Push draincock into the radiator tank opening.
(3) Tighten the draincock by turning clockwise until it stops.
(4) Fill the cooling system (Refer to 7 - COOLING/ENGINE - STANDARD PROCEDURE).

THERMOSTAT HOUSING

REMOVAL

(1) Disconnect negative battery cable.
(2) Drain cooling system below thermostat housing level (Refer to 7 - COOLING/ENGINE - STANDARD PROCEDURE).
(3) Remove thermostat (Refer to 7 - COOLING/ENGINE/ENGINE COOLANT THERMOSTAT - REMOVAL).
(4) Disconnect engine coolant temperature sensor.
(5) Disconnect heater supply hose.
(6) **Turbocharger equipped vehicles:**
- Recover the refrigerant from the refrigerant system(Refer to 24 - HEATING & AIR CONDITIONING - STANDARD PROCEDURE).
- Disconnect A/C suction line from A/C compressor (Refer to 24 - HEATING & AIR CONDITIONING/PLUMBING/SUCTION LINE - REMOVAL).

(7) Remove housing attaching bolts (Fig. 39).
(8) Remove housing and gasket (Fig. 39).

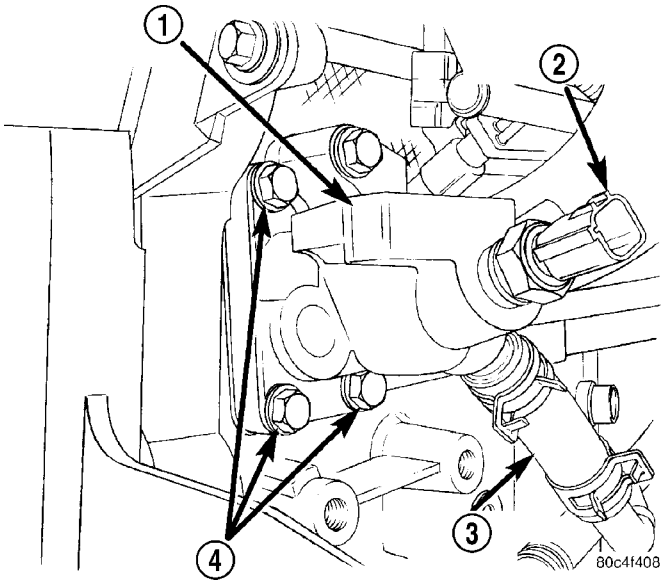

Fig. 39 Thermostat Housing

1 - THERMOSTAT HOUSING
2 - COOLANT TEMPERATURE SENSOR
3 - HOSE-HEATER SUPPLY
4 - BOLTS

THERMOSTAT HOUSING (Continued)

INSTALLATION

(1) Clean all gasket sealing surfaces.

(2) Install gasket and housing (Fig. 39). Tighten bolts to 28 N·m (20 ft. lbs.).

(3) **Turbocharger equipped vehicles:**

• Connect A/C suction line to A/C compressor (Refer to 24 - HEATING & AIR CONDITIONING/ PLUMBING/SUCTION LINE - INSTALLATION).

• Evacuate the refrigerant system(Refer to 24 - HEATING & AIR CONDITIONING - STANDARD PROCEDURE).

• Charge the refrigerant system(Refer to 24 - HEATING & AIR CONDITIONING - STANDARD PROCEDURE).

(4) Connect heater supply hose.

(5) Connect engine coolant temperature sensor.

(6) Install thermostat (Refer to 7 - COOLING/ENGINE/ENGINE COOLANT THERMOSTAT - INSTALLATION).

(7) Fill cooling system (Refer to 7 - COOLING/ENGINE - STANDARD PROCEDURE).

(8) Connect negative battery cable.

WATER PUMP

DIAGNOSIS AND TESTING

WATER PUMP

A quick flow test to determine if the water pump is working effectively is to check heater system for proper operation. A defective pump will not provide an adequate flow of heated coolant through the system.

WARNING: DO NOT REMOVE THE COOLING SYSTEM PRESSURE CAP WITH THE SYSTEM HOT AND UNDER PRESSURE BECAUSE SERIOUS BURNS FROM COOLANT CAN OCCUR.

Another flow test to help determine water pump operation is as follows:

(1) Remove cooling system pressure cap.

(2) Remove a small amount of coolant from the system.

(3) Start the engine and warm up until thermostat opens.

(4) With the thermostat open and coolant level low, visually inspect for coolant flow. If flow is present, the water pump is pumping coolant through the system.

REMOVAL

(1) Drain cooling system (Refer to 7 - COOLING/ ENGINE - STANDARD PROCEDURE).

(2) Remove timing belt (Refer to 9 - ENGINE/ VALVE TIMING/TIMING BELT AND SPROCKETS - REMOVAL).

(3) Remove camshaft sprockets and rear timing belt cover (Refer to 9 - ENGINE/VALVE TIMING/ TIMING BELT AND SPROCKETS - REMOVAL).

(4) Remove screws attaching water pump to engine. Remove pump (Fig. 40).

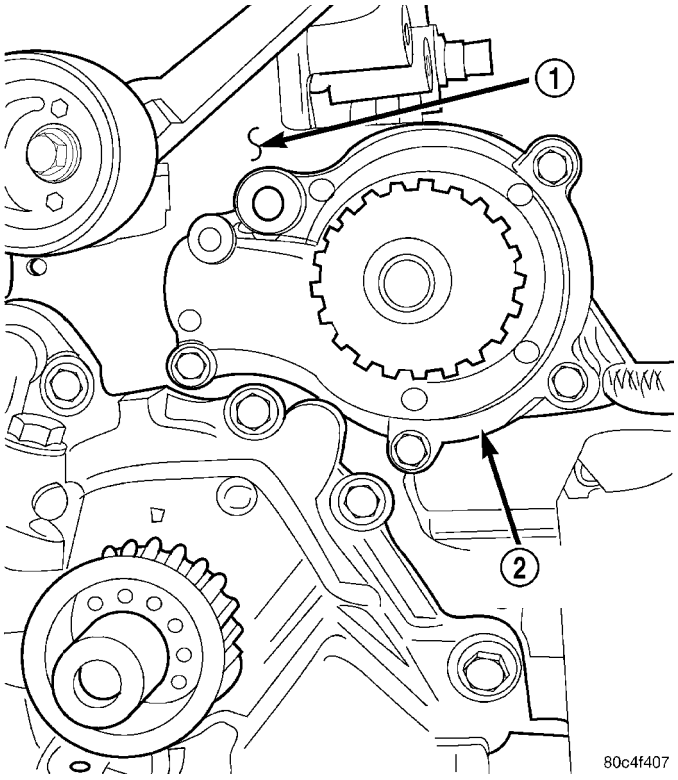

Fig. 40 Water Pump

1 - CYLINDER BLOCK
2 - WATER PUMP

INSPECTION

Replace water pump body assembly if it has any of these defects:

(1) Cracks or damage on the body.

(2) Coolant leaks from the shaft seal, evident by wet coolant traces on the pump body.

(3) Loose or rough turning bearing.

(4) Impeller rubs either the pump body or the engine block.

(5) Impeller loose or damaged.

(6) Sprocket or sprocket flange loose or damaged.

INSTALLATION

(1) Apply Mopar® Dielectric Grease to new O-ring before installation (Fig. 41).

(2) Install O-ring gasket in water pump body groove (Fig. 41).

WATER PUMP (Continued)

CAUTION: Make sure O-ring gasket is properly seated in water pump groove before tightening screws. An improperly located O-ring may cause damage to the O-ring, resulting in a coolant leak.

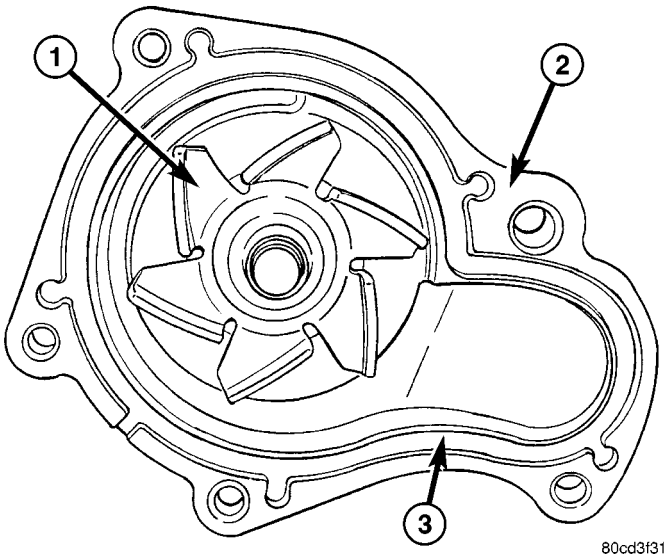

Fig. 41 Water Pump Body

1 - IMPELLER
2 - WATER PUMP BODY
3 - O-RING LOCATING GROOVE

(3) Assemble pump body to block (Fig. 40) and tighten screws to 12 N·m (105 in. lbs.).

(4) Rotate pump by hand to check for freedom of movement.

(5) Fill cooling system (Refer to 7 - COOLING/ENGINE - STANDARD PROCEDURE). Pressurize cooling system to 103 Kpa (15 psi) with pressure tester and check water pump shaft seal and O-ring for leaks.

(6) Install rear timing belt cover and camshaft sprockets (Refer to 9 - ENGINE/VALVE TIMING/TIMING BELT AND SPROCKETS - INSTALLATION).

(7) Install timing belt (Refer to 9 - ENGINE/VALVE TIMING/TIMING BELT AND SPROCKETS - INSTALLATION).

WATER PUMP INLET TUBE

REMOVAL

The water pump inlet tube connects the water pump to the radiator and heater core. This tube is sealed by an O-ring and held in place by fasteners to the block.

CAUTION: Do not use any sharp tools to remove hoses from inlet tube. This may cause the tube to leak.

(1) Drain cooling system (Refer to 7 - COOLING/ENGINE - STANDARD PROCEDURE).

(2) Remove upper radiator closure panel and center brace (Refer to 23 - BODY/EXTERIOR/RADIATOR CLOSURE PANEL - REMOVAL).

(3) Remove lower radiator hose and heater return hose from the inlet tube (Fig. 42).

(4) Remove the inlet tube to block bolts (Fig. 42).

(5) Rotate tube while removing from the engine block (Fig. 43).

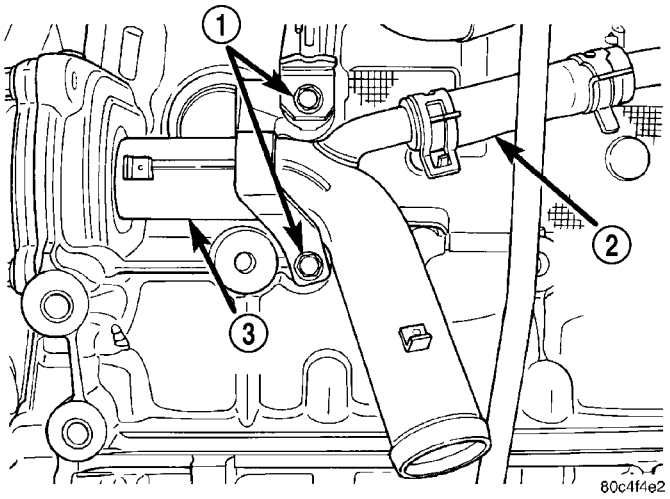

Fig. 42 Water Pump Inlet Tube Fasteners

1 - BOLTS
2 - HOSE - HEATER RETURN
3 - WATER PUMP INLET TUBE

WATER PUMP INLET TUBE (Continued)

INSTALLATION

(1) Inspect the O-ring for damage before installing the tube (Fig. 43). Replace O-ring as necessary.

(2) Lubricate O-ring with Mopar® Dielectric Grease and install inlet tube into the cylinder block opening (Fig. 43).

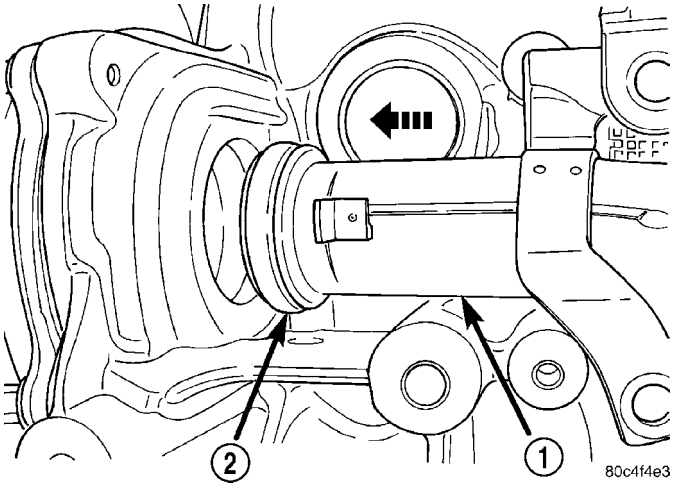

Fig. 43 Water Pump Inlet Tube—Installation

1 - TUBE
2 - O-RING

(3) Install inlet tube bolts and tighten to 12 N·m (105 in. lbs.) (Fig. 42).

(4) Connect lower radiator hose and heater return hose to inlet tube (Fig. 42).

(5) Install upper radiator closure panel and center brace (Refer to 23 - BODY/EXTERIOR/RADIATOR CLOSURE PANEL - INSTALLATION).

(6) Fill cooling system (Refer to 7 - COOLING/ENGINE - STANDARD PROCEDURE).

(7) Pressure test system to 103 kPa (15 psi) and check for leaks.

CLEANING	65
INSPECTION	65
INSTALLATION	66

TRANSMISSION COOLER HOSES

DESCRIPTION

The transmission oil cooling circuit uses special aggressive fittings for the transmission oil cooler hoses. Whenever a transmission oil cooler hose is removed from a transmission fitting (at transmission), it must be cut off flush with the fitting, and a service splice kit must be used upon reassembly. Refer to instructions provided with splice kit. Whenever a transmission oil cooler hose is removed from a transmission oil cooler fitting (at radiator), it must be replaced with a new hose. Removing the hose from the aggressive fitting will scrape material from inside the hose making the hose larger. Failure to replace the hose or install a service splice kit will result in transmission oil leaks.

When hose clamp replacement is necessary, replace with constant tension spring type hose clamps. Always use proper hose clamp pliers on clamps. Use of improper hose clamp pliers may bend hose clamps out-of-round resulting in transmission oil leaks.

AUTOMATIC TRANSMISSION OIL COOLER

DESCRIPTION

Non - Turbo

The automatic transmission oil cooler consists of an external air-to-oil type mounted in front of the radiator (Fig. 1). Rubber hoses connect the oil coolers to the automatic transmission. Use only approved transmission oil cooler hoses and clamps for replacement. The hoses are molded to the fit space available.

Turbo

The automatic transmission oil cooler consists of an external air-to-oil type mounted in front of the air conditioning condenser (Fig. 2). Rubber hoses connect the oil cooler to the automatic transmission. Use only approved transmission oil cooler hoses and clamps for replacement. The hoses are molded to the fit space available.

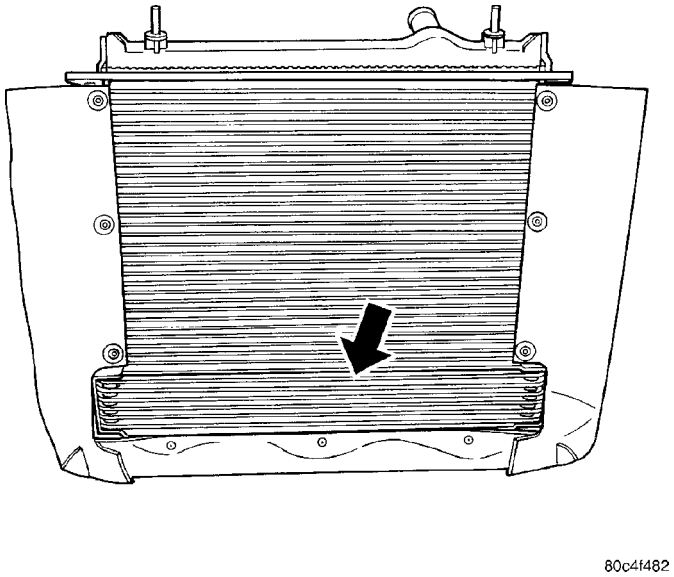

Fig. 1 Automatic Transmission Oil Cooler

REMOVAL

Non - Turbo

(1) Remove front fascia (Refer to 13 - FRAME & BUMPERS/BUMPERS/FRONT FASCIA - REMOVAL).

NOTE: When the transaxle cooler lines are removed from the rolled-groove type fittings at the cooler and transaxle, damage to the inner wall of hose will occur. To prevent potential leakage, the cooler hoses and clamps must be replaced.

(2) Loosen hose clamps. Disconnect hoses from transmission oil cooler (Fig. 3).

(3) Remove screws attaching transmission oil cooler to radiator (Fig. 3).

(4) Remove transmission oil cooler (Fig. 3).

AUTOMATIC TRANSMISSION OIL COOLER (Continued)

4 - SCREWS

Turbo

NOTE: When the transaxle cooler lines are removed from the rolled-groove type fittings at the cooler and transaxle, damage to the inner wall of hose will occur. To prevent potential leakage, the cooler hoses and clamps must be replaced.

(1) Remove grille (Refer to 23 - BODY/EXTERIOR/GRILLE - REMOVAL).

(2) Remove upper radiator closure panel (Refer to 23 - BODY/EXTERIOR/RADIATOR CLOSURE PANEL - REMOVAL) (Fig. 4).

(3) Remove radiator closure panel center brace (Fig. 4).

(4) Remove fasteners attaching transmission oil cooler to air conditioning condenser (Fig. 5).

(5) Loosen hose clamps. Disconnect hoses from transmission oil cooler.

(6) Remove transmission oil cooler.

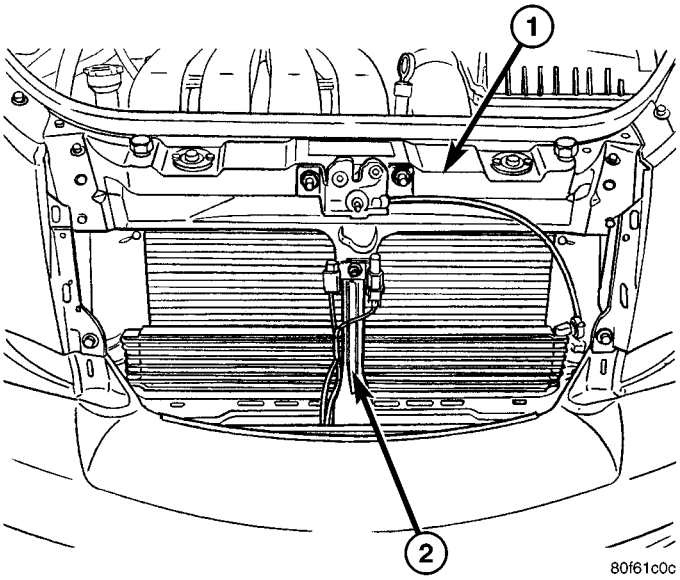

Fig. 4 Upper Radiator Closure Panel and Center Brace

1 - UPPER RADIATOR CLOSURE PANEL
2 - CENTER BRACE

CLEANING

Check the external cooler for debris on the cooling fin surfaces. Clean as necessary.

INSPECTION

Inspect all hoses, tubes, clamps and connections for leaks, cracks, or damage. Replace as necessary. Use only approved transmission oil cooler hoses that are molded to fit the space available.

Inspect external coolers for leaks, loose mounts, or damage. Replace as necessary.

AUTOMATIC TRANSMISSION OIL COOLER (Continued)

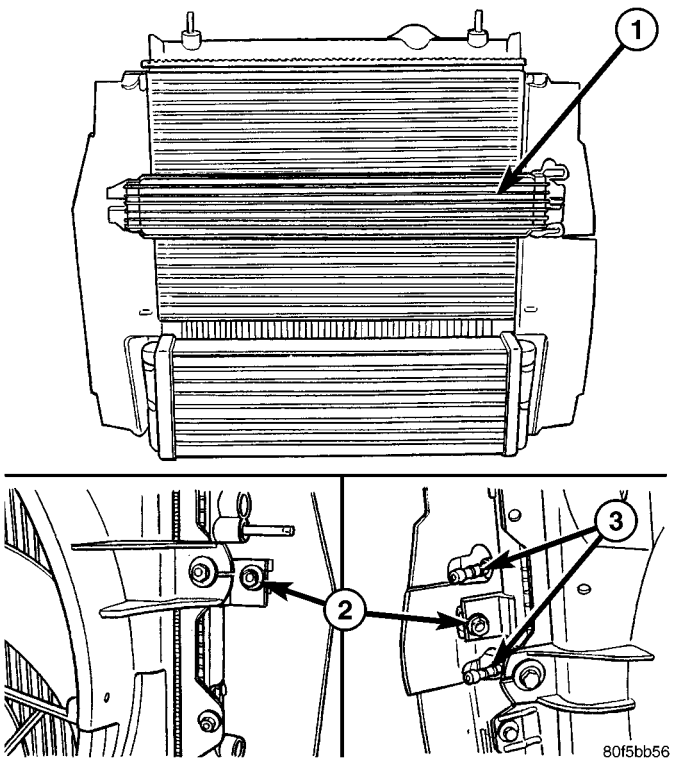

Fig. 5 Automatic Transmission Oil Cooler - Removal/Installation 2.4L Turbo

1 - TRANSMISSION OIL COOLER
2 - ATTACHING SCREWS
3 - HOSE FITTINGS

INSTALLATION

Non - Turbo

(1) Install transmission oil cooler and tighten screws to 8 N·m (70 in. lbs.) (Fig. 3).

NOTE: When the transaxle cooler lines are removed from the rolled-groove type fittings at the cooler and transaxle, damage to the inner wall of hose will occur. To prevent potential leakage, the cooler hoses and clamps must be replaced.

(2) Replace automatic transmission cooler hoses and clamps.

(3) Connect hoses to cooler (Fig. 3). Tighten hose clamps to 2 N·m (18 in. lbs.).

(4) Install front fascia (Refer to 13 - FRAME & BUMPERS/BUMPERS/FRONT FASCIA - INSTALLATION).

(5) Start engine and check transmission fluid level. Adjust level as necessary.

Turbo

NOTE: When the transaxle cooler lines are removed from the rolled-groove type fittings at the cooler and transaxle, damage to the inner wall of hose will occur. To prevent potential leakage, the cooler hoses and clamps must be replaced.

(1) Replace automatic transmission cooler hoses and clamps.

(2) Connect hoses to cooler. Tighten hose clamps to 2 N·m (18 in. lbs.).

(3) Install transmission oil cooler and tighten screws to 8 N·m (70 in. lbs.) (Fig. 5).

(4) Install radiator closure panel center brace (Fig. 4).

(5) Install upper radiator closure panel (Refer to 23 - BODY/EXTERIOR/RADIATOR CROSSMEMBER - INSTALLATION) (Fig. 4).

(6) Install grille (Refer to 23 - BODY/EXTERIOR/GRILLE - INSTALLATION).

(7) Start engine and check transmission fluid level. Adjust level as necessary.

AUDIO

DESCRIPTION

Several combinations of radio receivers are offered. The audio system uses an ignition switched source of battery current so that the system will only operate when the ignition switch is in the RUN or ACCESSORY positions.

An optional navigation radio (RB3) is available on this vehicle. With this system, the operator has the option of choosing a street address, point of interest, trip itinerary and other features outlined in the operator's manual.

The audio system includes the following components:

- Antenna
- Antenna - satellite radio (if equipped)
- Radio noise suppression components
- Radio receiver
- Satellite receiver module (if equipped)
- Speakers

Certain functions and features of the audio system rely upon resources shared with other electronic modules in the vehicle over the Programmable Communication Interface (PCI) bus network. The data bus network allows the sharing of sensor information. For diagnosis of these electronic modules or of the data bus network, the use of a DRB III® scan tool and the proper Diagnostic Procedures manual are recommended.

OPERATION

The audio system components are designed to provide audio entertainment and information through the reception, tuning and amplification of locally broadcast radio signals in both the Amplitude Modulating (AM) and Frequency Modulating (FM) commercial frequency ranges.

The available satellite radio system is a subscription based service. Information sent by satellite is transmitted to the roof mounted antenna, then to the satellite receiver module. The operator then has the choice of multiple music/information channels.

The available navigation radio system receives GPS signals from up to eight satellites to display the position and direction of the vehicle. Map information is supplied through a DVD-ROM. An electronic gyrosensor and the vehicle's speed sensor enable the system to display the present vehicle position even in locations where GPS signals may be blocked.

AUDIO (Continued)

When a destination is selected, the navigation system uses information from the map to quickly calculate a route. As the vehicle is driven along the chosen route, the operator is guided with pictorial displays and voice prompts. For complete operating instructions, refer to the manual included with the vehicle.

The audio system components operate on battery current received through a fuse in the Junction Block (JB) on a fused ignition switch output (run-acc) circuit so that the system will only operate when the ignition switch is in the On or Accessory positions.

DIAGNOSIS AND TESTING - AUDIO

Any diagnosis of the Audio system should begin with the use of the DRB III ® diagnostic tool. For information on the use of the DRB III®, refer to the appropriate Diagnostic Service information.

For complete circuit diagrams, refer to the appropriate wiring information.

WARNING: DISABLE THE AIRBAG SYSTEM BEFORE ATTEMPTING ANY STEERING WHEEL, STEERING COLUMN, SEAT BELT TENSIONER, SIDE AIRBAG, OR INSTRUMENT PANEL COMPONENT DIAGNOSIS OR SERVICE. DISCONNECT AND ISOLATE THE BATTERY NEGATIVE (GROUND) CABLE, THEN WAIT TWO MINUTES FOR THE AIRBAG SYSTEM CAPACITOR TO DISCHARGE BEFORE PERFORMING FURTHER DIAGNOSIS OR SERVICE. THIS IS THE ONLY SURE WAY TO DISABLE THE AIRBAG SYSTEM. FAILURE TO TAKE THE PROPER PRECAUTIONS COULD RESULT IN ACCIDENTAL AIRBAG DEPLOYMENT AND POSSIBLE PERSONAL INJURY.

AUDIO SYSTEM DIAGNOSIS

CONDITION	POSSIBLE CAUSES	CORRECTION
NO AUDIO	1. Fuse inoperative.	1. Check radio fuse and Ignition-Off Draw (IOD) fuse in Junction Block (JB). Replace fuses, if required.
	2. Radio connector damaged.	2. Check for loose or corroded radio connector. Repair, if required.
	3. Wiring damaged.	3. Check for shorted or open wires. Repair wiring, if required.
	4. Radio ground damaged.	4. Check for continuity between radio chassis and a known good ground. There should be continuity. Repair ground, if required.
	5. Radio inoperative.	5. Refer to appropriate Diagnostic Service information.
	6. Speakers inoperative.	6. Replace speaker as necessary.
NO SATELLITE RADIO AUDIO (PERFORM ALL DIAGNOSIS OUTDOORS)	1. Subscription service has expired (with subscription expired, one channel is still available)	1. Contact satellite radio provider.
	2. Items on roof blocking satellite antenna.	2. Remove or reposition items to allow clear space around antenna.
	3. Damaged satellite antenna cable.	3. Replace satellite antenna cable.
	3. Damaged satellite antenna.	3. Replace satellite antenna.
NO RADIO DISPLAY	1. Fuse inoperative.	1. Check radio fuse and Ignition-Off Draw (IOD) fuse in Junction Block (JB). Replace fuses, if required.
	2. Radio connector damaged.	2. Check for loose or corroded radio connector. Repair, if required.
	3. Wiring damaged.	3. Check for battery voltage at radio connector. Repair wiring, if required.

AUDIO (Continued)

CONDITION	POSSIBLE CAUSES	CORRECTION
	4. Radio ground damaged.	4. Check for continuity between radio chassis and a known good ground. There should be continuity. Repair ground, if required.
	5. Radio inoperative.	5. Refer to appropriate Diagnostic Service information.
CLOCK WILL NOT KEEP SET TIME	1. Fuse inoperative.	1. Check Ignition-Off Draw (IOD) fuse in the Junction Block (JB). Replace fuse, if required.
	2. Radio connector damaged.	2. Check for loose or corroded radio connector. Repair, if required.
	3. Wiring damaged.	3. Check for battery voltage at radio connector. Repair wiring, if required.
	4. Radio ground damaged.	4. Check for continuity between radio chassis and a known good ground. There should be continuity. Repair ground, if required.
	5. Radio inoperative.	5. Refer to appropriate Diagnostic Service information.
SOUND DISTORTION (VIBRATION FROM SPEAKER AREA, BUZZING - HUMMING)	1. Door trim panel loose or missing fasteners.	1. Inspect door trim panel and correct as necessary. Replace any missing fasteners.
	2. Water shield loose or misaligned.	2. Inspect water shield and adjust as required.
	3. Items placed in door trim panel map pockets vibrating or moving from side to side.	3. Remove items from door trim panel. Ensure that vibration is no longer present.
POOR RADIO RECEPTION	1. Antenna damaged or inoperative.	1. Diagnose and replace antenna if necessary.
	2. Radio ground damaged.	2. Check for continuity between radio chassis and a known good ground. There should be continuity. Repair ground, if required.
	3. Radio noise suppression inoperative.	3. Repair or replace ground strap as necessary.
	4. Radio inoperative.	4. Refer to appropriate Diagnostic Service information.
NO/POOR TAPE OPERATION	1. Damaged tape.	1. Insert known good tape and test operation.
	2. Foreign objects behind tape door.	2. Remove foreign objects and test operation.
	3. Dirty cassette tape head.	3. Clean head with Mopar Cassette Head Cleaner.
	4. Inoperative radio.	4. Exchange or replace radio, if required.
NO COMPACT DISC OPERATION	1. Damaged CD.	1. Insert known good CD and test operation.
	2. Foreign material on CD.	2. Clean CD and test operation.
	3. Condensation on CD or optics.	3. Allow temperature of vehicle interior to stabilize and test operation.
	4. Inoperative radio.	4. Refer to appropriate Diagnostic Service information.

ANTENNA BODY & CABLE

DESCRIPTION

The antenna body and cable are secured below the fender panel by the antenna cap nut through a mounting hole in the side of the right front fender. The primary coaxial antenna cable is then routed beneath the fender sheet metal and through a entry hole in the right cowl side panel into the interior of the vehicle. Inside the vehicle, the primary coaxial cable is connected to a secondary instrument panel antenna coaxial cable with an in-line connector that is located behind the right end of the instrument panel. The secondary coaxial cable is then routed behind the instrument panel to the back of the radio.

OPERATION

The antenna body and cable connects the antenna mast to the radio. The radio antenna is an electromagnetic circuit component used to capture radio frequency signals that are broadcast by local commercial radio stations in both the Amplitude Modulating (AM) and Frequency Modulating (FM) frequency ranges. These electromagnetic radio frequency signals induce small electrical modulations into the antenna as they move past the mast. The antenna body transfers the weak electromagnetic radio waves induced into the rigid antenna mast into the center conductor of the flexible primary antenna coaxial cable. The braided outer shield of the antenna coaxial cable is grounded through both the antenna body and the radio chassis, effectively shielding the radio waves as they are conducted to the radio. The radio then tunes and amplifies the weak radio signals into stronger electrical signals in order to operate the audio system speakers.

DIAGNOSIS AND TESTING - ANTENNA BODY AND CABLE

The following four tests are used to diagnose the antenna with an ohmmeter:

- **Test 1** - Mast to ground test
- **Test 2** - Tip-of-mast to tip-of-conductor test
- **Test 3** - Body ground to battery ground test
- **Test 4** - Body ground to antenna coaxial cable shield test.

WARNING: DISABLE THE AIRBAG SYSTEM BEFORE ATTEMPTING ANY STEERING WHEEL, STEERING COLUMN, SEAT BELT TENSIONER, SIDE AIRBAG, OR INSTRUMENT PANEL COMPONENT DIAGNOSIS OR SERVICE. DISCONNECT AND ISOLATE THE BATTERY NEGATIVE (GROUND) CABLE, THEN WAIT TWO MINUTES FOR THE AIRBAG SYSTEM CAPACITOR TO DISCHARGE BEFORE PERFORMING FURTHER DIAGNOSIS OR SERVICE. THIS IS THE ONLY SURE WAY TO DISABLE THE AIRBAG SYSTEM. FAILURE TO TAKE THE PROPER PRECAUTIONS COULD RESULT IN ACCIDENTAL AIRBAG DEPLOYMENT AND POSSIBLE PERSONAL INJURY.

The ohmmeter test lead connections for each test are shown in the illustration (Fig. 1).

NOTE: This model has a two-piece antenna coaxial cable. Tests 2 and 4 must be conducted in two steps to isolate an antenna cable problem. First, test the primary antenna cable (integral to the antenna body and cable) from the coaxial cable connector under the right end of the instrument panel near the right cowl side inner panel to the antenna body. Then, test the secondary antenna cable (instrument panel antenna cable) from the coaxial cable connector under the right end of the instrument panel near the right cowl side inner panel to the coaxial cable connector at the radio.

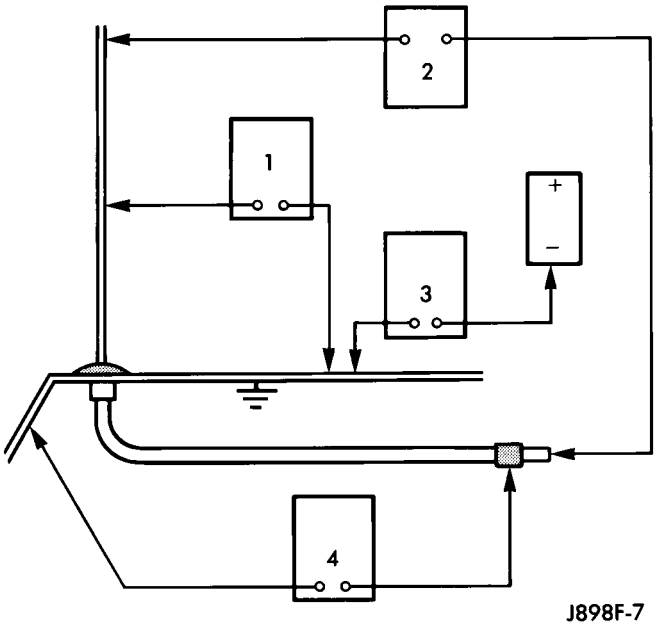

Fig. 1 ANTENNA TEST - TYPICAL

TEST 1

Test 1 determines if the antenna mast is insulated from ground. Proceed as follows:

(1) Disconnect and isolate the antenna coaxial cable connector under the right end of the instrument panel near the right cowl side inner panel.

(2) Touch one ohmmeter test lead to the tip of the antenna mast (below tip if ball tip is plastic). Touch the other test lead to the antenna cap nut. Check the ohmmeter reading for continuity.

(3) There should be no continuity. If OK, go to Test 2. If not OK, replace the faulty antenna body and cable.

ANTENNA BODY & CABLE (Continued)

TEST 2

Test 2 checks the antenna conductor components for an open circuit. This test should be performed first on the entire antenna circuit, from the antenna mast to the center conductor of the coaxial cable connector at the radio. If an open circuit is detected, each of the three antenna conductor components (antenna mast, antenna body and primary cable unit, instrument panel antenna secondary cable) should be isolated and tested individually to locate the exact component that is the source of the open circuit. To begin this test, proceed as follows:

(1) Disconnect the instrument panel (secondary) antenna cable coaxial connector from the back of the radio.

(2) Touch one ohmmeter test lead to the tip of the antenna mast. Touch the other test lead to the center conductor pin of the instrument panel antenna cable coaxial connector for the radio. Check the ohmmeter reading for continuity.

(3) There should be continuity. The ohmmeter should register only a fraction of an ohm resistance. High or infinite resistance indicates a damaged or open antenna conductor. If OK, go to Test 3. If not OK, isolate and test each of the individual antenna conductor components. Replace only the faulty antenna conductor component.

TEST 3

Test 3 checks the condition of the vehicle body ground connection. To begin this test, proceed as follows:

(1) This test must be performed with the battery positive cable disconnected from the battery. Disconnect and isolate both battery cables, negative cable first.

(2) Reconnect the battery negative cable.

(3) Touch one ohmmeter test lead to a good clean ground point on the vehicle fender. Touch the other test lead to the battery negative terminal post. Check the ohmmeter reading for continuity.

(4) There should be continuity. The ohmmeter should register less than one ohm resistance. High or infinite resistance indicates a loose, corroded, or damaged connection between the battery negative terminal and the vehicle body. If OK, go to Test 4. If not OK, check the battery negative cable connection to the vehicle body and the radio noise suppression ground strap connections to the engine and the vehicle body for being loose or corroded. Clean or tighten these connections as required.

TEST 4

Test 4 checks the condition of the connection between the antenna coaxial cable shield and the vehicle body ground as follows:

(1) Disconnect and isolate the antenna coaxial cable connector under the right end of the instrument panel near the right cowl side inner panel.

(2) Touch one ohmmeter test lead to a good clean ground point on the vehicle fender. Touch the other test lead to the outer crimp on the antenna coaxial cable connector under the right end of the instrument panel near the right cowl side inner panel. Check the ohmmeter reading for continuity.

(3) There should be continuity. The ohmmeter should register less than one ohm resistance. High or infinite resistance indicates a loose, corroded, or damaged connection between the antenna body and the vehicle body or between the antenna body and the antenna coaxial cable shield. If not OK, clean the antenna body to fender mating surfaces and tighten the antenna cap nut to specifications.

(4) Check the resistance again with an ohmmeter. If the resistance is still more then one ohm, replace the faulty antenna body and cable.

REMOVAL

(1) Disconnect and isolate the battery negative cable.

(2) Remove antenna mast by unscrewing mast from antenna body. On vehicles equipped with manual retractable antenna, lower antenna fully.

(3) Remove shroud (if equipped).

(4) Remove antenna nut and adapter (Fig. 2).

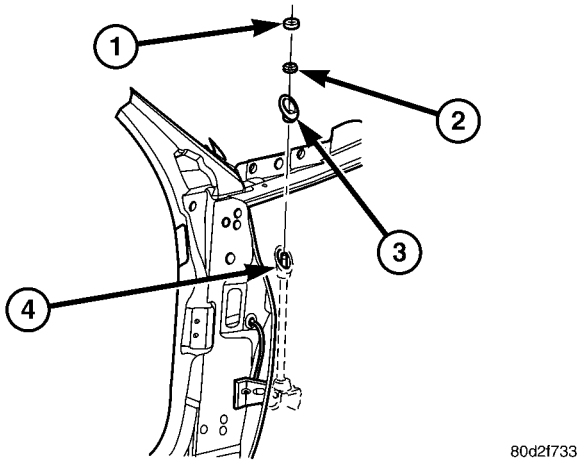

Fig. 2 ANTENNA BODY AND CABLE

1 - ANTENNA NUT SHROUD (IF EQUIPPED)
2 - ANTENNA NUT
3 - ANTENNA ADAPTER
4 - ANTENNA BODY AND CABLE

(5) Disconnect antenna body cable from instrument panel antenna cable.

(6) Remove inner fender shield as necessary to gain access to mounting fasteners.

(7) Remove antenna body and cable assembly from fender (Fig. 3).

ANTENNA BODY & CABLE (Continued)

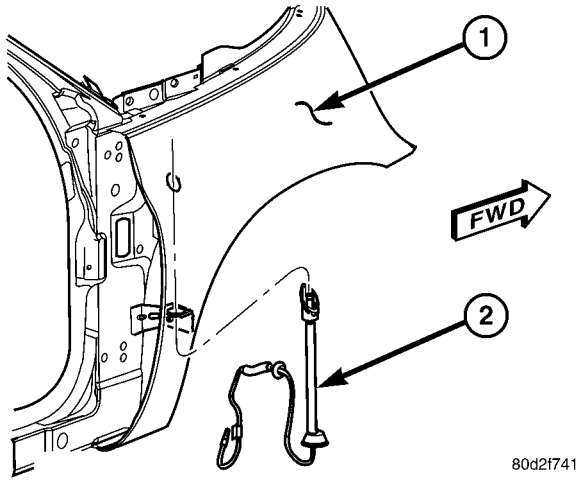

Fig. 3 ANTENNA MOUNTING

1 - FENDER
2 - ANTENNA BODY AND CABLE

INSTALLATION

(1) Position antenna body and cable assembly into fender.

(2) Insert antenna cable through the opening in fender.

(3) Seat the grommet in the side panel and connect the cable to the instrument panel harness connector.

(4) Install antenna nut and adapter.

(5) Install shroud (if equipped).

(6) Install the inner fender shield.

(7) Install antenna mast. Tighten to 5 N·m (46 in. lbs.). **Ensure that the antenna mast is fully seated on antenna base and that there is no gap between the mast and base.**

(8) Connect the antenna cable to the instrument panel antenna cable.

(9) Install the right side cowl trim panel.

(10) Connect the battery negative cable.

ANTENNA - EXPORT

REMOVAL

(1) Disconnect and isolate the battery negative cable.

(2) Lower the headliner as necessary to access antenna mounting fastener (Refer to 23 - BODY/INTERIOR/HEADLINER - REMOVAL).

(3) Disconnect antenna cable and electrical harness connector (Fig. 4).

(4) Remove the mounting fastener.

(5) Remove antenna from roof panel.

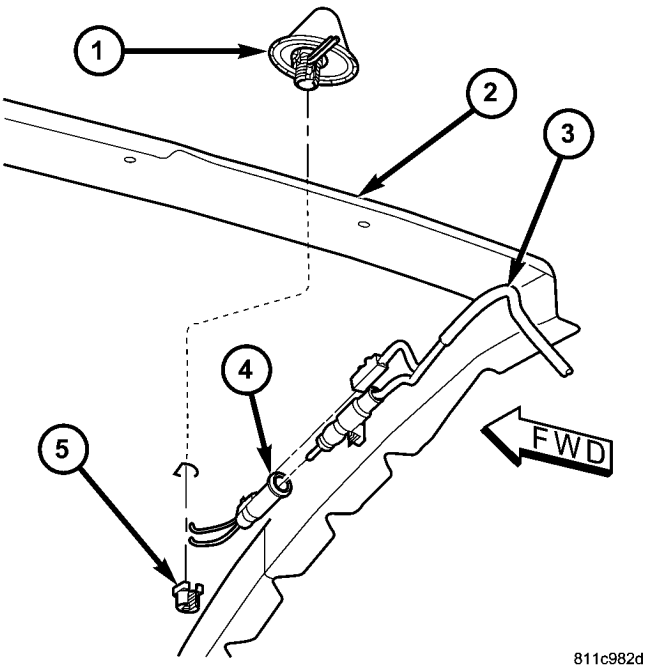

Fig. 4 ANTENNA - EXPORT

1 - ANTENNA
2 - ROOF PANEL
3 - ELECTRICAL HARNESS
4 - ANTENNA CABLE (PART OF ANTENNA)
5 - MOUNTING FASTENER

INSTALLATION

(1) Position antenna to roof panel.

(2) Install and tighten mounting fastener.

(3) Connect antenna cable and electrical harness connector.

(4) Raise headliner (Refer to 23 - BODY/INTERIOR/HEADLINER - INSTALLATION).

(5) Connect battery negative cable.

ANTENNA - NAVIGATION

REMOVAL

(1) Disconnect and isolate the battery negative cable.

(2) Remove the instrument panel top cover (Refer to 23 - BODY/INSTRUMENT PANEL/INSTRUMENT PANEL TOP COVER - REMOVAL).

(3) Remove the radio (Refer to 8 - ELECTRICAL/AUDIO/RADIO - REMOVAL).

(4) Remove the antenna mounting fasteners (Fig. 5).

(5) Remove antenna cable from wire harness.

INSTALLATION

(1) Position antenna cable to wire harness. Secure into place.

(2) Install antenna mounting fasteners.

ANTENNA - NAVIGATION (Continued)

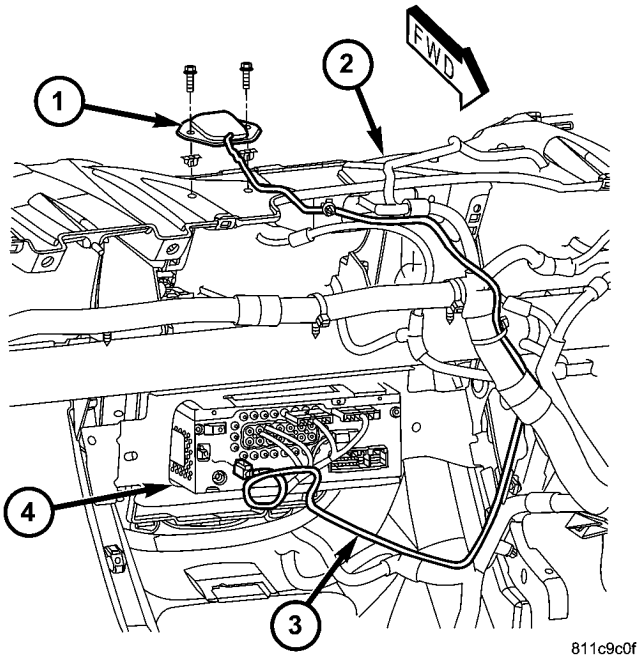

Fig. 5 ANTENNA - NAVIGATION RADIO

1 - NAVIGATION RADIO ANTENNA
2 - INSTRUMENT PANEL
3 - ANTENNA CABLE
4 - RADIO

(3) Install radio (Refer to 8 - ELECTRICAL/AUDIO/RADIO - INSTALLATION).

(4) Install instrument panel top cover (Refer to 23 - BODY/INSTRUMENT PANEL/INSTRUMENT PANEL TOP COVER - INSTALLATION).

(5) Connect battery negative cable.

ANTENNA - SATELLITE RADIO

DESCRIPTION

The satellite radio antenna is secured by adhesive foam and two retainers which protrude through a hole in the roof panel. Two wires from the antenna are connected to the body harness above the headliner.

OPERATION

The satellite radio antenna receives signals from orbiting satellites and sends these signals to the satellite receiver module. The satellite radio antenna must have open space in which to operate. Items carried on the roof, parking inside etc. can have an effect on the antenna's ability to receive signals.

REMOVAL

(1) Disconnect and isolate the battery negative cable.

(2) Lower the rear portion of the headliner as necessary to access underside of antenna (Refer to 23 - BODY/INTERIOR/HEADLINER - REMOVAL).

(3) A adhesive removal tool can be created by using a 18 to 24 inch piece of nylon cord wrapped around two handles (Fig. 6). Using the removal tool, guide the nylon cord under the dust seal on the forward side of the antenna. Grab the handles and work the cord through the adhesive. Continue this for 360° around the antenna.

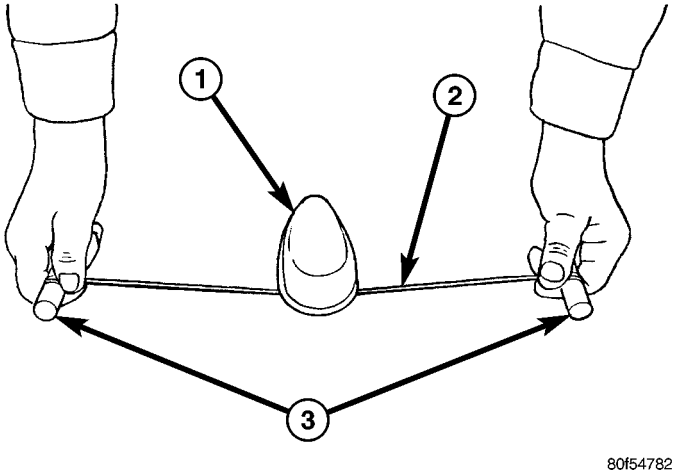

Fig. 6 SATELLITE RADIO ANTENNA REMOVAL

1 - SATELLITE ANTENNA
2 - NYLON CORD
3 - WOODEN DOWEL ROD

(4) Disconnect the wire harness connectors from the antenna.

(5) From inside the vehicle, and using a flat bladed tool, depress one of the retaining tabs on the antenna. Push up the one side of the antenna connector through the roof panel. Depress the other side of the connector and remove the antenna.

(6) Remove any remaining adhesive from roof panel with isopropyl alcohol and a lint free cloth. If original antenna is being reinstalled, remove adhesive from antenna mounting surface.

INSTALLATION

(1) If original antenna is being reinstalled, remove backing from patch adhesive and apply to antenna base.

(2) Remove backing from the adhesive on the antenna.

(3) Insert wire harness through hole in roof panel. Press antenna into position until both retainers snap into place.

(4) Connect wire harness connectors to antenna.

(5) Install headliner (Refer to 23 - BODY/INTERIOR/HEADLINER - INSTALLATION).

(6) Connect battery negative cable.

ANTENNA CABLE - SATELLITE RADIO

DESCRIPTION

The satellite radio antenna connects the roof mounted antenna to the satellite receiver module. It has two connectors at each end and is routed above the headliner, then behind the left quarter panel trim.

REMOVAL

(1) Disconnect and isolate the battery negative cable.

(2) Remove the D-pillar trim panel (Refer to 23 - BODY/INTERIOR/D-PILLAR TRIM - REMOVAL).

(3) Remove the left rear quarter trim panel (Refer to 23 - BODY/INTERIOR/LEFT QUARTER TRIM PANEL - REMOVAL).

(4) Lower the rear portion of the headliner as necessary to access the underside of the satellite antenna (Refer to 23 - BODY/INTERIOR/HEADLINER - REMOVAL).

(5) Detach the antenna cable from the body harness (Fig. 7). Disconnect wire harness connectors at each end of the cable.

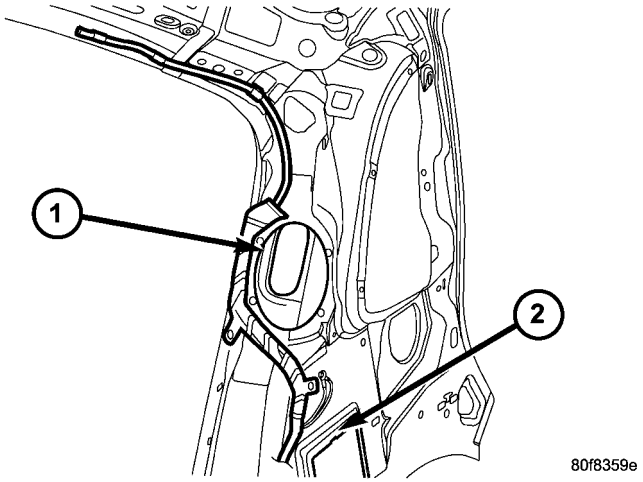

Fig. 7 ANTENNA CABLE - SATELLITE RADIO

1 - ANTENNA CABLE - SATELLITE RADIO
2 - SATELLITE RECEIVER MODULE

INSTALLATION

(1) Secure the antenna cable to the body harness. Connect the wire harness connectors at each end of the antenna.

(2) Install the headliner (Refer to 23 - BODY/INTERIOR/HEADLINER - INSTALLATION).

(3) Install the left rear quarter trim panel (Refer to 23 - BODY/INTERIOR/LEFT QUARTER TRIM PANEL - INSTALLATION).

(4) Install the D-pillar trim panel (Refer to 23 - BODY/INTERIOR/D-PILLAR TRIM - INSTALLATION)

(5) Connect the battery negative cable.

RADIO

DESCRIPTION

Available radios for this vehicle include:

- AM/FM/cassette with CD changer control feature (RBY, RBT or RAD sales code)
- AM/FM/cassette/CD/ (RAZ sales code)
- AM/FM/CD with CD changer control (RBK sales code)
- AM/FM/CD with 6 CD changer (RBQ sales code)
- AM/FM/CD (REK sales code) - export only
- AM/FM/CD GPS Navigation (RB3 sales code)

All factory-installed radios can communicate on the Programmable Communications Interface (PCI) data bus network.

COUNTRY CODE AND CABIN EQ SETTING - REK RADIO ONLY

The REK radio may require the country code and cabin EQ setting to be set if not programmed correctly.

If battery power is lost to radio, the anti-theft code must be entered before radio will operate.

If the region the vehicle will be driven in uses 10 kHz spacing on the AM band (i.e. 950, 960 etc.), set the Country Code to “USA”. If the region uses 9 kHz spacing, has LW and MW Bands, and uses RDS (i.e. AF, PTY, TA, etc.), set the radio for “EUR”. If neither of the previous settings apply, and the vehicle is not being driven in Japan, set the radio to “ROW”. Vehicles driven in Japan should have the radio set to “JPN”. The following chart list selected country codes and radio broadcast standards.

To enter the country code and EQ setting, use a scan tool.

OPERATION

The radio receiver operates on ignition switched battery current that is available only when the ignition switch is in the On or Accessory positions. The electronic digital clock function of the radio operates on fused battery current supplied through the IOD fuse, regardless of the ignition switch position.

REMOVAL

(1) Disconnect and isolate the battery negative cable.

(2) Remove instrument panel center bezel.

(3) Remove mounting fasteners and remove radio from instrument panel (Fig. 8).

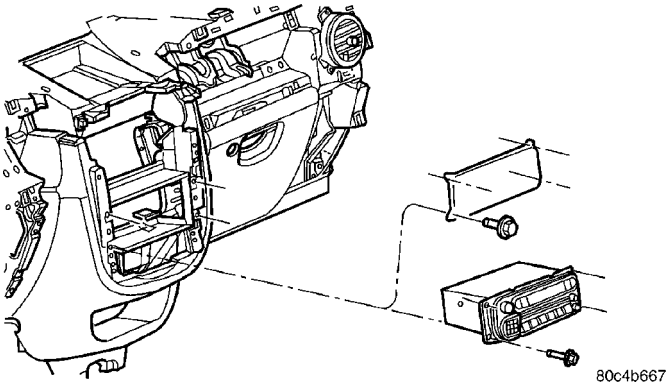

Fig. 8 RADIO

(4) Disconnect wire harness connector from radio.

CAUTION: Pulling the antenna cable straight out of the radio without pulling on the locking antenna connector could damage the cable or radio.

RADIO (Continued)

(5) Disconnect the antenna cable by pulling the locking antenna connector away from the radio (Fig. 9).

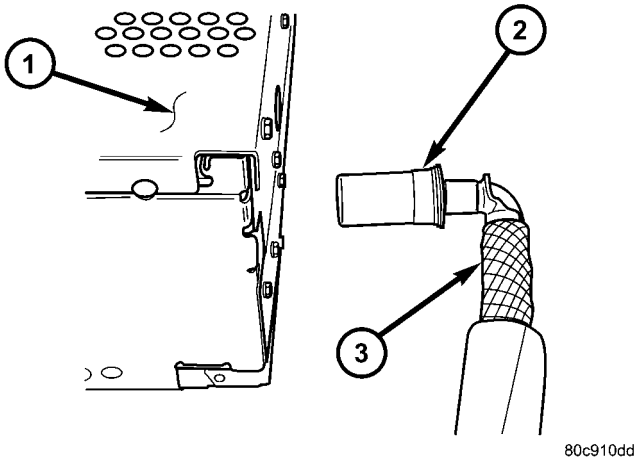

Fig. 9 ANTENNA TO RADIO

1 - RADIO
2 - LOCKING ANTENNA CONNECTOR
3 - INSTRUMENT PANEL ANTENNA CABLE

INSTALLATION

(1) Connect the wire harness connector and antenna cable to radio.

(2) Insert radio into instrument panel.

(3) Install mounting fasteners. Tighten to 2 N·m (20 in. lbs.).

(4) Install instrument panel center bezel.

(5) Connect battery negative cable.

RADIO NOISE SUPPRESSION COMPONENTS

DESCRIPTION

Radio noise suppression devices are factory-installed standard equipment on this vehicle. Radio Frequency Interference (RFI) and ElectroMagnetic Interference (EMI) can be produced by any on-board or external source of electromagnetic energy. These electromagnetic energy sources can radiate electromagnetic signals through the air, or conduct them through the vehicle electrical system.

When the audio system converts RFI or EMI to an audible acoustic wave form, it is referred to as radio noise. This undesirable radio noise is generally manifested in the form of “buzzing,” “hissing,” “popping,” “clicking,” “crackling,” and/or “whirring” sounds. In most cases, RFI and EMI radio noise can be suppressed using a combination of vehicle and component grounding, filtering and shielding techniques. This vehicle is equipped with factory-installed radio noise suppression devices that were designed to minimize exposure to typical sources of RFI and EMI; thereby, minimizing radio noise complaints.

Radio noise suppression is accomplished primarily through circuitry or devices that are integral to the radios, audio power amplifiers and other on-board electrical components such as generators, wiper motors, blower motors, and fuel pumps that have been found to be potential sources of RFI or EMI. External radio noise suppression devices that are used on this vehicle to control RFI or EMI, and can be serviced, include the following:

- **Ground straps** - This length of braided ground strap has an eyelet terminal connector crimped to each end. They are located in various locations on the vehicle.
- **Radio Noise Suppression Capacitor** - This component is attached near the exhaust manifold.
- **Resistor-type spark plugs** - This type of spark plug has an internal resistor connected in series between the spark plug terminal and the center electrode to help reduce the production of electromagnetic radiation that can result in radio noise.

OPERATION

There are two common strategies that can be used to suppress Radio Frequency Interference (RFI) and ElectroMagnetic Interference (EMI) radio noise. The first suppression strategy involves preventing the production of RFI and EMI electromagnetic signals at their sources. The second suppression strategy involves preventing the reception of RFI and EMI electromagnetic signals by the audio system components.

The use of braided ground straps in key locations is part of the RFI and EMI prevention strategy. These ground straps ensure adequate ground paths, particularly for high current components such as many of those found in the starting, charging, ignition, engine control and transmission control systems. An insufficient ground path for any of these high current components may result in radio noise caused by induced voltages created as the high current seeks alternative ground paths through components or circuits intended for use by, or in close proximity to the audio system components or circuits.

Preventing the reception of RFI and EMI is accomplished by ensuring that the audio system components are correctly installed in the vehicle. Loose, corroded or improperly soldered wire harness connections, improperly routed wiring and inadequate audio system component grounding can all contribute to the reception of RFI and EMI. A properly grounded antenna body and radio chassis, as well as a shielded antenna coaxial cable with clean and tight connections will each help reduce the potential for reception of RFI and EMI.

RADIO NOISE SUPPRESSION COMPONENTS (Continued)

REMOVAL

ENGINE GROUND STRAP

(1) Disconnect and isolate the battery negative cable.

(2) Remove bolt from engine cylinder head (Fig. 10), (Fig. 11), (Fig. 12).

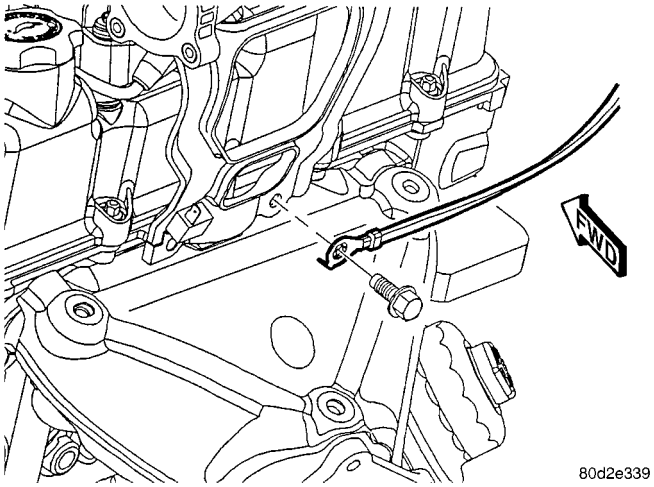

Fig. 10 GROUND STRAP TO ENGINE 1.6L

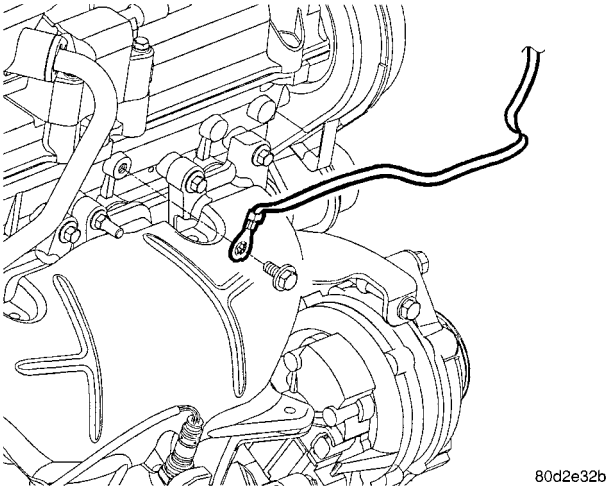

Fig. 11 GROUND STRAP TO ENGINE 2.0/2.4L

(3) Remove bolt from strut tower and remove strap (Fig. 13).

HOOD HINGE GROUND STRAP

(1) Disconnect and isolate the battery negative cable.

(2) Remove bolt from fender (Fig. 14).

(3) Remove bolt from hood and remove strap.

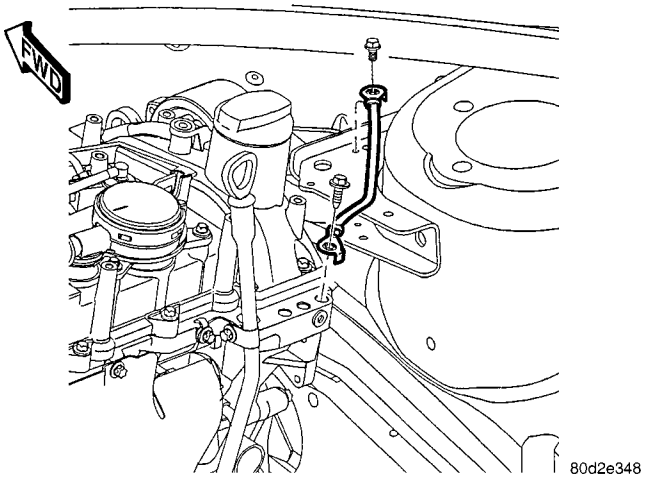

Fig. 12 GROUND STRAP TO ENGINE 2.2L

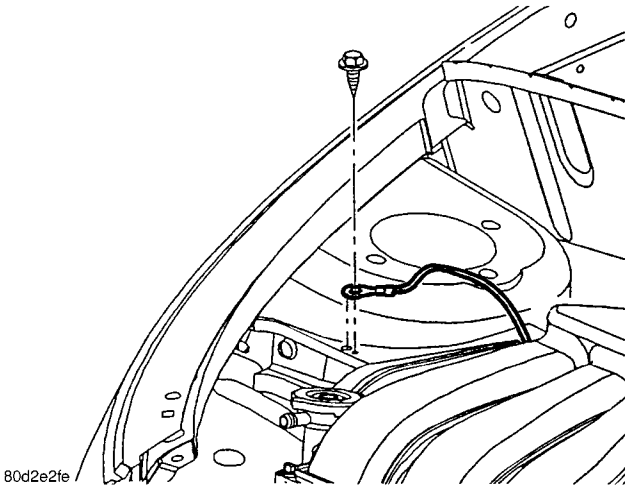

Fig. 13 GROUND STRAP TO STRUT TOWER

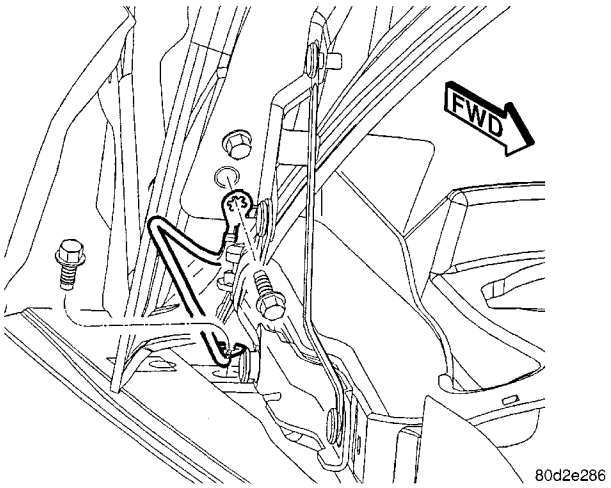

Fig. 14 HOOD HINGE GROUND STRAP

RADIO NOISE SUPPRESSION COMPONENTS (Continued)

MUFFLER GROUND STRAP

(1) Disconnect and isolate the battery negative cable.

(2) Remove bolt from rear floor pan (Fig. 15).

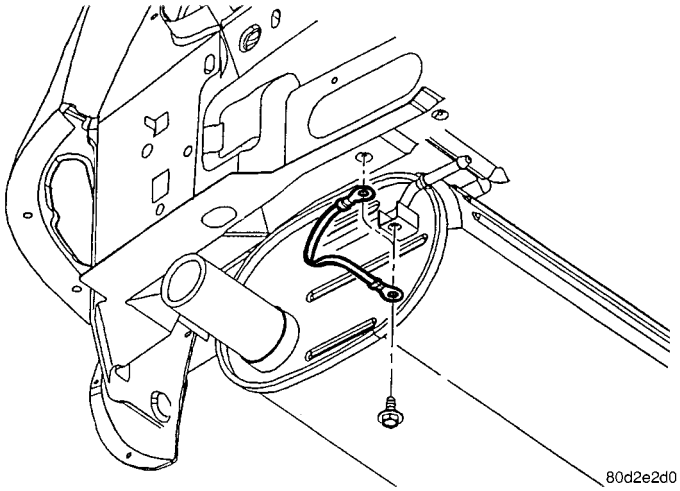

Fig. 15 MUFFLER GROUND STRAP

(3) Remove bolt from muffler and remove strap.

RADIO NOISE SUPPRESSION CAPACITOR

(1) Disconnect and isolate the battery negative cable.

(2) Disconnect electrical harness connector from capacitor (Fig. 16).

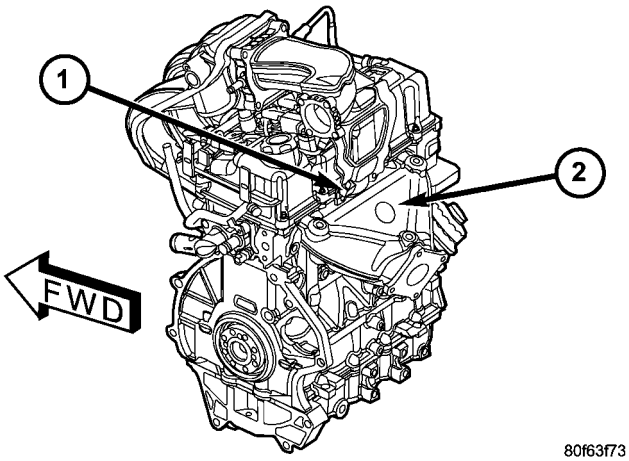

Fig. 16 RADIO NOISE CAPACITOR - TYPICAL

1 - RADIO NOISE CAPACITOR
2 - EXHAUST MANIFOLD

(3) Remove bolt from capacitor and remove capacitor.

STRUT BRACKET TO BODY GROUND STRAP

(1) Disconnect and isolate the battery negative cable.

(2) Remove bolt from strut (Fig. 17)

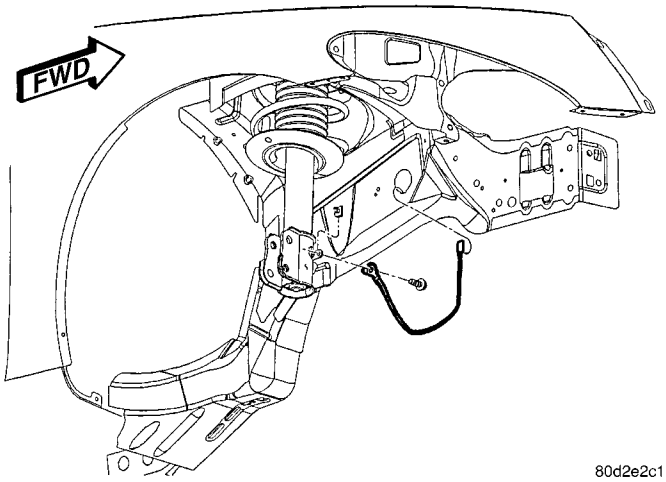

Fig. 17 STRUT BRACKET TO BODY GROUND STRAP

(3) Remove strap from frame rail.

INSTALLATION

ENGINE GROUND STRAP

(1) Install strap and bolt to strut tower. Tighten bolt to 12 N·m (105 in. lbs.).

(2) Install strap and bolt to engine cylinder head. Tighten bolt to 28 N·m (21 ft. lbs.).

(3) Connect battery negative cable.

HOOD HINGE GROUND STRAP

(1) Install strap and bolt to fender. Tighten bolt to 4 N·m (35 in. lbs.).

(2) Install strap and bolt to hood. Tighten bolt to 4 N·m (35 in. lbs.).

(3) Connect battery negative cable.

MUFFLER GROUND STRAP

(1) Install strap and bolt to rear floor pan. Tighten bolt to 8 N·m (75 in. lbs.).

(2) Install strap and bolt to muffler. Tighten bolt to 8 N·m (75 in. lbs.).

(3) Connect battery negative cable.

RADIO NOISE SUPPRESSION CAPACITOR

(1) Install capacitor and bolt.

(2) Connect electrical harness connector to capacitor.

(3) Connect battery negative cable.

STRUT BRACKET TO BODY GROUND STRAP

(1) Install strap to frame rail.

CAUTION: Ensure that ground strap does not come in contact with brake hose. Damage to brake hose can result.

RADIO NOISE SUPPRESSION COMPONENTS (Continued)

(2) Install strap and bolt to strut. Tighten bolt to 12 N·m (105 in. lbs.).
(3) Connect battery negative cable.

SATELLITE RECEIVER MODULE

DESCRIPTION

The satellite receiver module is located behind the left rear trim panel. It is mounted to a bracket which is fastened to the inner quarter panel sheet metal.

OPERATION

The satellite receiver module receives signals from the roof mounted antenna and processes this information before it is sent to the radio. The module operates on both battery and accessory feed circuits and will operate with the ignition key in the run or accessory position only.

REMOVAL

NOTE:
If the owner's satellite service was active before the satellite receiver module was replaced the new satellite receiver module will have to be activated. The existing satellite receiver module will have to be deactivated before the replacement satellite receiver module can be activated.
To activate Sirius satellite radio service, call Sirius at their toll-free number. Please have the following information available when activating a system:
- **Electronic Serial Number / Sirius Identification Number (ESN/SID) of the unit to be replaced**
- **ESN/SID of the replacement receiver**
- **Vehicle Owner's name and address**
- **VIN**

The ESN/SID number can be obtained through the radio display by following the steps in the satellite radio owners manual.
The vehicle must be outside with the audio system powered on, in the satellite radio mode, to receive the activation signal.

(1) Disconnect and isolate the battery negative cable.
(2) Remove the left rear quarter trim panel (Refer to 23 - BODY/INTERIOR/LEFT QUARTER TRIM PANEL - REMOVAL).
(3) Remove the mounting bracket fasteners (Fig. 18).
(4) Disconnect the wire harness connectors.
(5) Remove the module from the mounting bracket.

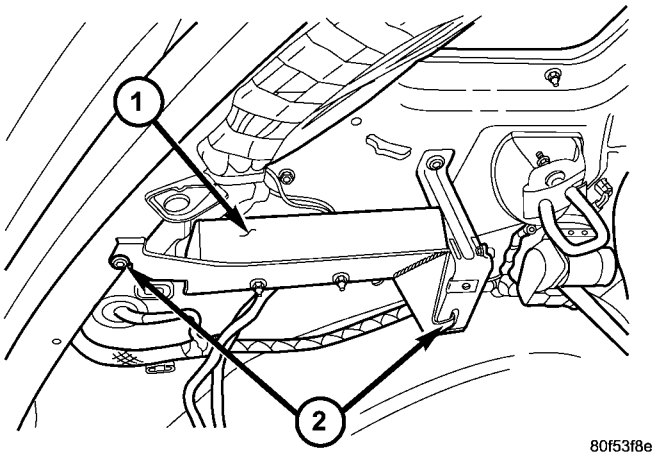

Fig. 18 SATELLITE RECEIVER MODULE

1 - SATELLITE RECEIVER MODULE
2 - MOUNTING BRACKET FASTENERS

INSTALLATION

NOTE:
If the owner's satellite service was active before the satellite receiver module was replaced the new satellite receiver module will have to be activated. The existing satellite receiver module will have to be deactivated before the replacement satellite receiver module can be activated.
To activate Sirius satellite radio service, call Sirius at their toll-free number. Please have the following information available when activating a system:
- **Electronic Serial Number / Sirius Identification Number (ESN/SID) of the unit to be replaced**
- **ESN/SID of the replacement receiver**
- **Vehicle Owner's name and address**
- **VIN**

The ESN/SID number can be obtained through the radio display by following the steps in the satellite radio owners manual.
The vehicle must be outside with the audio system powered on, in the satellite radio mode, to receive the activation signal.

(1) Position the module to the mounting bracket. Tighten mounting fasteners to 6 N·m (53 in. lbs.).
(2) Connect wire harness connectors.
(3) Install mounting bracket and fasteners. Tighten to 5 N·m (45 in. lbs.).
(4) Install the left rear quarter trim panel (Refer to 23 - BODY/INTERIOR/LEFT QUARTER TRIM PANEL - INSTALLATION).
(5) Connect the battery negative cable.

SPEAKER

REMOVAL

FRONT DOOR SPEAKER

(1) Disconnect and isolate the battery negative cable.

(2) Remove the front door trim panel (Refer to 23 - BODY/DOOR - FRONT/TRIM PANEL - REMOVAL).

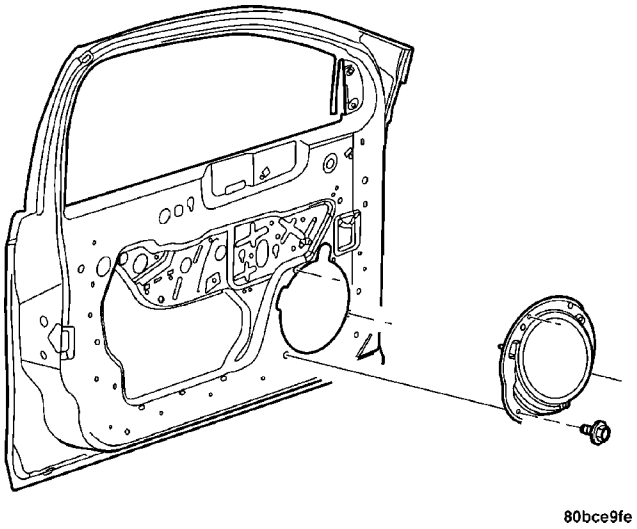

Fig. 19 FRONT DOOR SPEAKER

(3) Remove the speaker retaining screws (Fig. 19).

(4) Remove speaker and disconnect wire harness connector from speaker.

INSTRUMENT PANEL SPEAKER

(1) Disconnect and isolate the battery negative cable.

(2) Remove instrument panel top cover (Refer to 23 - BODY/INSTRUMENT PANEL/INSTRUMENT PANEL TOP COVER - REMOVAL).

(3) Remove speaker retaining screws (Fig. 20).

(4) Remove speaker and disconnect wire harness connector.

REAR SPEAKER - CONVERTIBLE

(1) Disconnect and isolate the battery negative cable.

(2) Remove the quarter trim panel.

(3) Remove the mounting fasteners.

(4) Remove speaker and disconnect the electrical harness connector (Fig. 21).

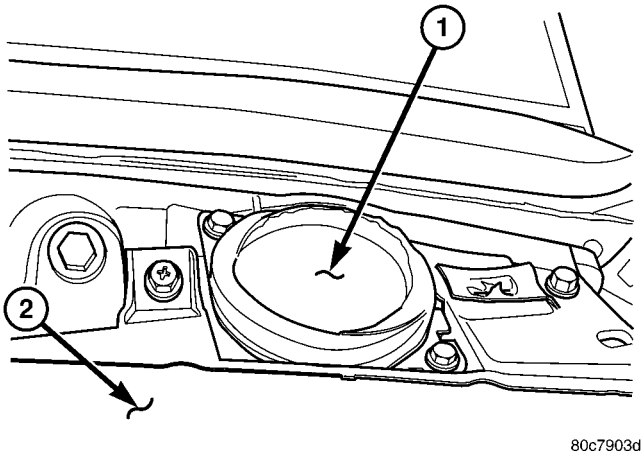

Fig. 20 INSTRUMENT PANEL SPEAKER

1 - INSTRUMENT PANEL SPEAKER
2 - INSTRUMENT PANEL

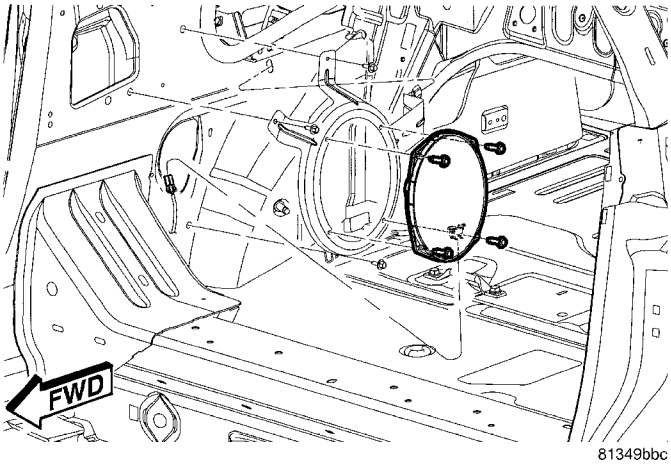

Fig. 21 REAR SPEAKER - CONVERTIBLE

REAR SPEAKER - SEDAN

(1) Disconnect and isolate the battery negative cable.

(2) Remove the D-pillar trim (Refer to 23 - BODY/INTERIOR/D-PILLAR TRIM - REMOVAL).

(3) Remove the speaker retaining screws (Fig. 22).

(4) Remove the speaker and disconnect the wire harness connector.

SPEAKER (Continued)

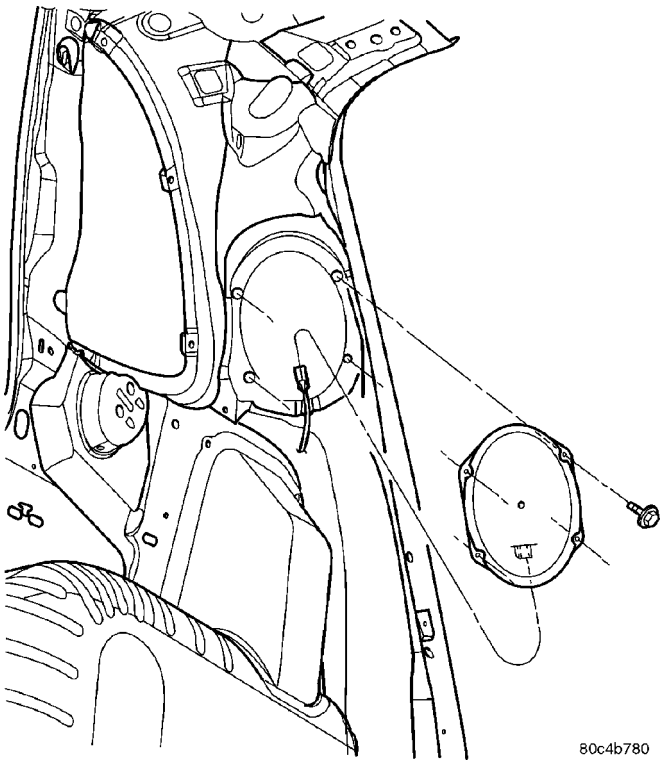

Fig. 22 REAR SPEAKER

INSTALLATION

FRONT DOOR SPEAKER

(1) Connect wire harness connector to speaker.
(2) Install speaker screws.
(3) Install the front door trim panel (Refer to 23 - BODY/DOOR - FRONT/TRIM PANEL - INSTALLATION).
(4) Connect the battery negative cable.

INSTRUMENT PANEL SPEAKER

(1) Connect wire harness connector to speaker.
(2) Install speaker screws.
(3) Install instrument panel top cover (Refer to 23 - BODY/INSTRUMENT PANEL/INSTRUMENT PANEL TOP COVER - INSTALLATION).
(4) Connect the battery negative cable.

REAR SPEAKER - CONVERTIBLE

(1) Connect electrical harness connector and position speaker.
(2) Install and tighten mounting fasteners.
(3) Install quarter trim panel.
(4) Connect battery negative cable.

REAR SPEAKER - SEDAN

(1) Connect wire harness connector to speaker.
(2) Install speaker screws.
(3) Install the D-pillar trim (Refer to 23 - BODY/INTERIOR/D-PILLAR TRIM - INSTALLATION).
(4) Connect the battery negative cable.

CHIME/BUZZER

DESCRIPTION

The chime module is located within, and serviced with the instrument cluster. The chime system provides the driver with warning chimes for:

- Seat Belt
- Exterior Lamps ON
- Key-In Ignition
- Warning Lamp Announcement
- Park Brake
- Low Fuel
- Door Ajar
- Reverse (Diesel and Turbo Only)

OPERATION

FASTEN SEAT BELT

The seat belt reminder system uses both visual and audible signals. A reminder chime with a red light on the instrument panel.

The system will always illuminate the seat belt reminder lamp for four to eight seconds when the ignition switch is turned to the ON position. The CHIME will sound during the same time interval if the driver's seat belt is not fastened. Passenger belts are not connected to the system.

HEADLAMPS REMINDER

These are the conditions that have to be met for the headlamps on, chime function to work:

- Headlamps ON and
- Driver's door open and
- Key removed from the ignition switch.

Chime should sound until headlamps are turned off or the drivers door is closed or the key is placed into the RUN position.

KEY IN IGNITION REMINDER

The chime will activate if the drivers door is opened and the key is in the ignition switch, with the ignition switch in either the OFF, LOCK, or the accessory (ACC) position.

DOOR AJAR CHIME

The chime will sound once when:

- Door opened and
- Ignition in RUN position and
- Vehicle speed is present

PARK BRAKE REMINDER

The cluster shall chime 10 times and continuously flash the brake indicator when:

- Park brake is activated and
- Vehicle speed greater than 3 mph is present.

LOW FUEL REMINDER

When the fuel level drops to about 1/8 tank, the fuel symbol will light and a single chime will sound. The light will remain on until fuel is added. If the fuel level drops to about 1/16 of a tank, the fuel symbol will flash several times and the chime will sound several times.

REVERSE CHIME (DIESEL and TURBO ONLY EQUIPPED WITH THE GETRAG MANUAL TRANSMISSION)

The chime provides the driver with an audible confirmation of the reverse gear selection with the Getrag manual transmission. When the vehicle is placed in REVERSE, with the ignition switch in the RUN position, the chime will sound six times (about 2 seconds). The chime will be a “fast” chime (same as door ajar). The transmission has reverse gear adjacent to first gear. There is a 6-7 second delay to accommodate mandatory bulb check and chimes (airbag, etc.). The cluster monitors the reverse circuit and chime as required.

CHIME/BUZZER (Continued)

DIAGNOSIS AND TESTING

DIAGNOSIS AND TESTING - BRAKE/PARK BRAKE INDICATOR

The brake/park brake indicator illuminates when the parking brake is applied with the ignition switch turned to the ON position. The same lamp will also illuminate if one of the two (hydraulic or ABS) service brake systems fail when the brake pedal is applied.

To test the system:

- As the ignition switch is turned to the START position the lamp should light.
- Turn ignition switch to the ON position and apply the parking brake. The lamp should light.

If lamp fails to light inspect for:

- A broken or disconnected wire at the switch
- Defective switch
- A burned out Light Emitting Diode (LED)
- A damaged circuit board

To test the service brake warning system, refer to Brakes, Diagnosis and Testing, Base Brake System Diagnosis Charts, Red Brake Warning Lamp.

DIAGNOSIS AND TESTING - CHIME CONDITIONS

NO TONE WHEN IGNITION SWITCH IS TURNED ON AND DRIVERS SEAT BELT IS UNBUCKLED

(1) Using an ohmmeter, with the seat belt fully retracted, check for continuity to ground at Pin 20 of the 26-way cluster harness connector. If OK, go to step 2. If not OK, repair as necessary.

(2) Using voltmeter, check for battery feed at Pin 4 of the 26-way cluster harness connector. Check for ignition feed at Pin 14 of the 26-way cluster harness connector. If not OK, repair as necessary.

NO FASTEN SEAT BELT LAMP WHEN IGNITION SWITCH IS ON

(1) Check for battery feed at cluster harness connector Pin 4.

(2) Check for ignition feed at cluster harness connector Pin 14. Repair as necessary.

NO TONE WHEN HEADLAMPS ARE ON AND DRIVERS DOOR IS OPEN

(1) Remove the key from the ignition.

(2) Check left door jamb switch for good ground when drivers door is open.

(3) Check for ground at Pin 1 of the 26-way cluster harness connector.

(4) Check for battery feed at cluster harness connector Pin 4 of the 26-way cluster harness connector.

(5) Check for NO voltage at Pin 14. Ignition voltage must not be present for the chime to work.

(6) Check headlamp switch.

NO TONE WHEN KEY IS LEFT IN IGNITION AND DRIVERS DOOR IS OPEN

(1) Check for continuity to ground at Pin 1 of the 26-way cluster harness connector. If OK, go to Step 4. If not OK, repair as necessary.

(2) Check pin 19 of the 26-way connector to ground while pulling key out/in from ignition switch. If not chime, check ignition switch for problems.

(3) Using voltmeter, check for battery feed at Pin 4 of the 26-way cluster harness connector. Check for NO ignition feed at Pin 14 of the 26-way cluster harness connector. If OK, go to Step 4. If not OK, repair as necessary.

(4) Open driver's door and ensure the ignition key is in the OFF, LOCK, or ACC position. Check for continuity to ground at Pin 9 of the 26-way cluster harness connector. If ground OK, replace cluster printed circuit board. If no ground, check key-in switch or door switch wiring and repair as necessary.

DIAGNOSIS AND TESTING - FASTEN SEAT BELTS

To test the fasten seat belts function, turn the ignition switch to the ON position with the driver's seat belt unbuckled and fully retracted. The seat belt warning lamp should light for four to eight seconds and the tone should sound three to five times.

If the lamp does not light, check the connection at the seat belt retractor. Replace as necessary.

DIAGNOSIS AND TESTING - KEY IN IGNITION

To test the key left in ignition function, insert key into the ignition and open the driver's door. Chime should sound until key is removed from ignition or driver's door is closed.

If these conditions are met and there is still a problem with the system, refer to Chime System Conditions in this section for further diagnosis and testing.

ANTILOCK BRAKE MODULE (MK25E)

DESCRIPTION

The Antilock Brake Module (ABM) is a microprocessor-based device which monitors the antilock brake system (ABS) during normal braking and controls it when the vehicle is in an ABS stop or when in a traction control situation. The ABM utilizes a 47-way electrical connector on the vehicle wiring harness. The power source for the ABM is through the ignition switch in the RUN or ON position.

The ABM is mounted to the HCU as part of the Integrated Control Unit (ICU) (Fig. 1). The ICU is located in the engine compartment on the inboard side of the left body frame rail. For information on the ICU, (Refer to 5 - BRAKES/HYDRAULIC/MECHANICAL/ICU (INTEGRATED CONTROL UNIT) - DESCRIPTION).

ANTILOCK BRAKE MODULE (MK25E) (Continued)

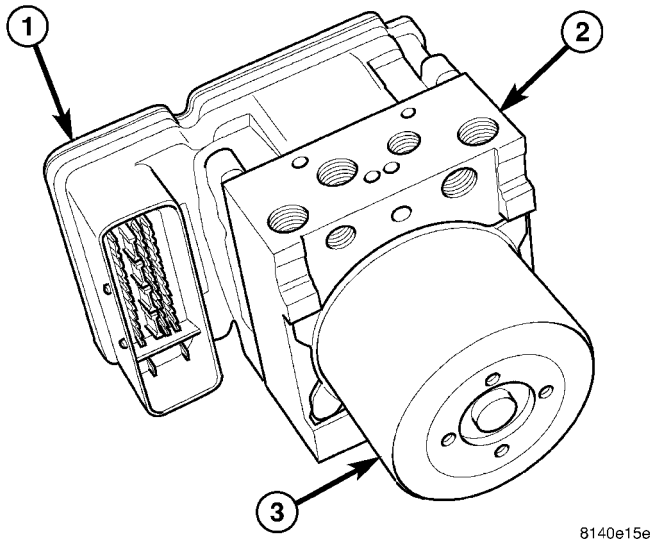

Fig. 1 Mk25e ICU

1 - ANTILOCK BRAKE MODULE (ABM)
2 - HYDRAULIC CONTROL UNIT (HCU)
3 - PUMP/MOTOR

OPERATION

The primary functions of the Antilock Brake Module (ABM) are to:

- monitor the Antilock Brake System (ABS) for proper operation.
- detect wheel locking or wheel slipping tendencies by monitoring the speed of all four wheels of the vehicle.
- control fluid modulation to the wheel brakes while the system is in an ABS mode or the traction control system is activated.
- store diagnostic information.
- provide communication to the scan tool while in diagnostic mode.

The ABM constantly monitors the antilock brake system for proper operation. If the ABM detects a fault, it will send a message to the mechanical instrument cluster (MIC) instructing it to turn on the amber ABS warning indicator lamp and disable the antilock braking system. The normal base braking system will remain operational.

The ABM continuously monitors the speed of each wheel through the signals generated by the wheel speed sensors to determine if any wheel is beginning to lock. When a wheel locking tendency is detected, the ABM commands the ABM command coils to actuate. The ABM command coils then open and close the valves in the HCU that modulate brake fluid pressure in some or all of the hydraulic circuits. The ABM continues to control pressure in individual hydraulic circuits until a locking tendency is no longer present.

The ABM contains a self-diagnostic program that monitors the antilock brake system for system faults. When a fault is detected, the amber ABS warning indicator lamp is turned on and the fault diagnostic trouble code (DTC) is then stored in a diagnostic program memory. These DTC's will remain in the ABM memory even after the ignition has been turned off. The DTC's can be read and cleared from the ABM memory by a technician using a scan tool. If not cleared with a scan tool, the fault occurrence and DTC will be automatically cleared from the memory after the identical fault has not been seen during the next 3,500 miles of vehicle operation.

ANTILOCK BRAKE MODULE INPUTS

- wheel speed sensors (four)
- brake lamp switch
- ignition switch
- system relay voltage
- ground
- traction control lamp actuation (if equipped)
- diagnostic communication (PCI)

ANTILOCK BRAKE MODULE OUTPUTS

- amber ABS warning indicator lamp actuation (through MIC)
- red BRAKE warning indicator lamp actuation (through MIC)
- traction control lamp (if equipped)
- diagnostic communication. (PCI)

REMOVAL

Due to packaging and limited space it is necessary to remove and disassemble the ICU to service the Antilock Brake Module on this vehicle. (Refer to 5 - BRAKES/HYDRAULIC/MECHANICAL/ICU (INTEGRATED CONTROL UNIT) - REMOVAL)

INSTALLATION

Due to packaging and limited space it is necessary to install the Antilock Brake Module on the HCU, then install the ICU on the vehicle as an assembly. (Refer to 5 - BRAKES/HYDRAULIC/MECHANICAL/ICU (INTEGRATED CONTROL UNIT) - ASSEMBLY)

CONTROLLER ANTILOCK BRAKE (MK20E)

DESCRIPTION

The controller antilock brake (CAB) is a microprocessor-based device which monitors the ABS system during normal braking and controls it when the vehicle is in an ABS stop. The CAB uses a 24-way electrical connector on the vehicle wiring harness. The power source for the CAB is through the ignition switch in the RUN or ON position. The CAB is on the PCI bus.

The CAB is mounted to the HCU as part of the Integrated Control Unit (ICU) (Fig. 2). Attached to the bottom of the HCU, it can be viewed from below, just above the transaxle and left halfshaft (Fig. 3). For information on the ICU, (Refer to 5 - BRAKES/ HYDRAULIC/MECHANICAL/ICU (INTEGRATED CONTROL UNIT) - DESCRIPTION)

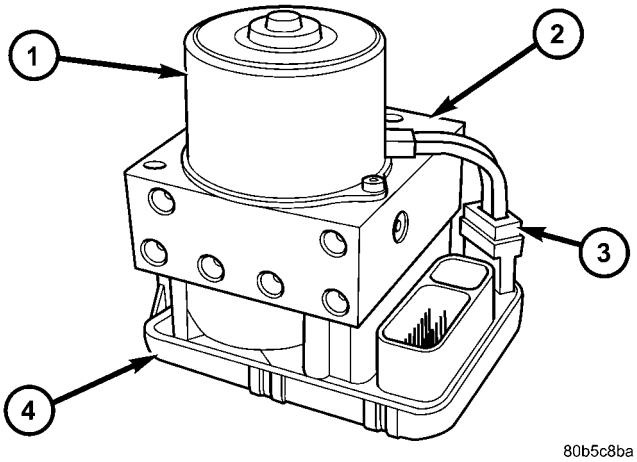

Fig. 2 Integrated Control Unit (ICU)

1 - PUMP/MOTOR
2 - HCU
3 - PUMP/MOTOR WIRING CONNECTOR
4 - CAB

OPERATION

The primary functions of the controller antilock brake (CAB) are to:

- monitor the antilock brake system for proper operation.
- detect wheel locking or wheel slipping tendencies by monitoring the speed of all four wheels of the vehicle.
- control fluid modulation to the wheel brakes while the system is in an ABS mode or the traction control system is activated.
- store diagnostic information.
- provide communication to the DRBIII® scan tool while in diagnostic mode.

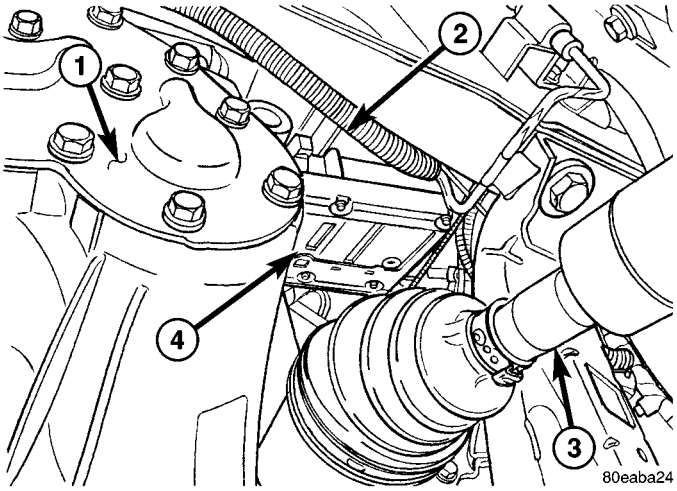

Fig. 3 CAB Location In Vehicle

1 - TRANSAXLE
2 - HCU
3 - LEFT HALFSHAFT
4 - CAB

The CAB constantly monitors the antilock brake system for proper operation. If the CAB detects a fault, it will send a message to the mechanical instrument cluster (MIC) instructing it to turn on the amber ABS warning indicator lamp and disable the antilock braking system. The normal base braking system will remain operational.

The CAB continuously monitors the speed of each wheel through the signals generated by the wheel speed sensors to determine if any wheel is beginning to lock. When a wheel locking tendency is detected, the CAB commands the CAB command coils to actuate. The CAB command coils then open and close the valves in the HCU that modulate brake fluid pressure in some or all of the hydraulic circuits. The CAB continues to control pressure in individual hydraulic circuits until a locking tendency is no longer present.

The CAB contains a self-diagnostic program that monitors the antilock brake system for system faults. When a fault is detected, the amber ABS warning lamp is turned on and the fault diagnostic trouble code (DTC) is then stored in a diagnostic program memory. These DTC's will remain in the CAB memory even after the ignition has been turned off. The DTC's can be read and cleared from the CAB memory by a technician using the DRB scan tool. If not cleared with a DRB scan tool, the fault occurrence and DTC will be automatically cleared from the CAB memory after the identical fault has not been seen during the next 3,500 miles of vehicle operation.

CONTROLLER ANTILOCK BRAKE INPUTS

- wheel speed sensors (four)
- brake lamp switch
- ignition switch

CONTROLLER ANTILOCK BRAKE (MK20E) (Continued)

- system relay voltage
- ground
- traction control lamp actuation (if equipped)
- diagnostic communication (PCI)

CONTROLLER ANTILOCK BRAKE OUTPUTS

- amber ABS warning indicator lamp actuation (through MIC)
- red BRAKE warning indicator lamp actuation (through MIC)
- traction control lamp (if equipped)
- diagnostic communication. (PCI)

REMOVAL

(1) Disconnect battery negative cable.

(2) Raise vehicle. (Refer to LUBRICATION & MAINTENANCE/HOISTING - STANDARD PROCEDURE)

(3) Disconnect pump/motor connector from CAB (Fig. 4).

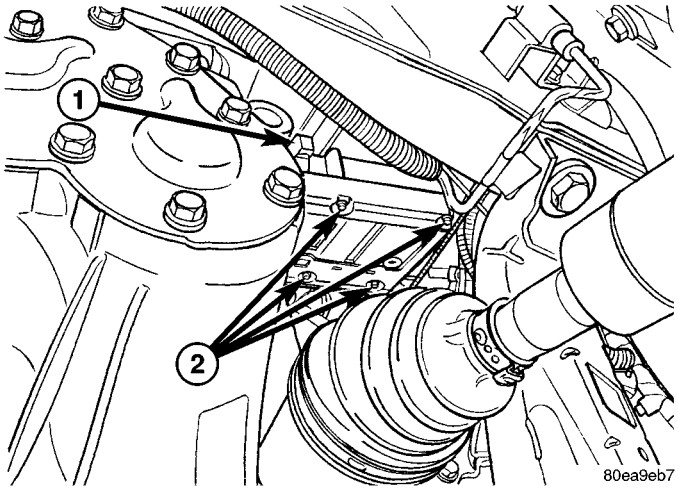

Fig. 4 CAB Mounting

1 - PUMP/MOTOR CONNECTOR
2 - CAB MOUNTING SCREWS

(4) Remove four screws securing CAB to HCU half of ICU (Fig. 4). Remove CAB from HCU.

(5) Pull outward on CAB connector lock and disconnect 24–way wiring connector. Remove CAB from vehicle.

INSTALLATION

(1) Connect 24–way wiring connector to CAB and push in connector lock.

(2) Align CAB with HCU half of ICU, then slide CAB up over HCU valves. Install four CAB mounting screws (Fig. 4). Tighten mounting screws to 2 N·m (17 in. lbs.) torque.

(3) Connect pump/motor connector (Fig. 4).

(4) Lower vehicle.

(5) Connect battery negative cable.

(6) Connect DRBIII® to vehicle to initialize system. Check and clear any faults.

DATA LINK CONNECTOR

DESCRIPTION

The data link connector is located inside the vehicle, below instrument panel next to the center column (Fig. 5).

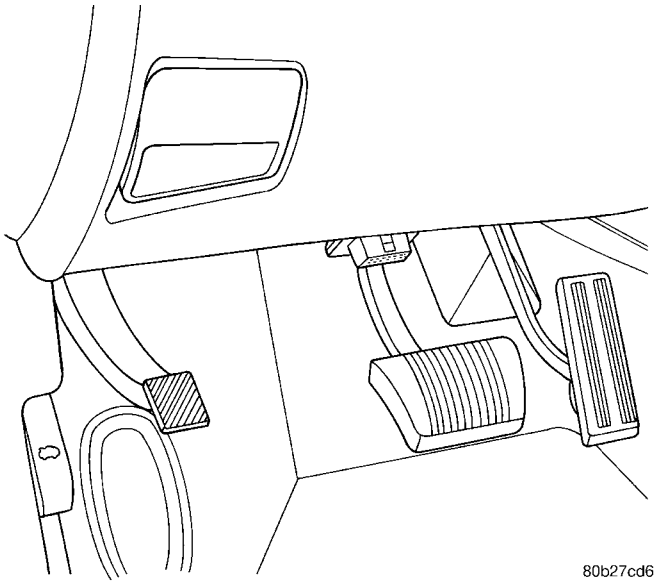

Fig. 5 DATA LINK CONNECTOR

OPERATION

The data link connector (diagnostic connector) links the DRB scan tool with the Powertrain Control Module (PCM). Refer to On-Board Diagnostics in the General Diagnosis section of this group.

HEATED SEAT MODULE

DESCRIPTION

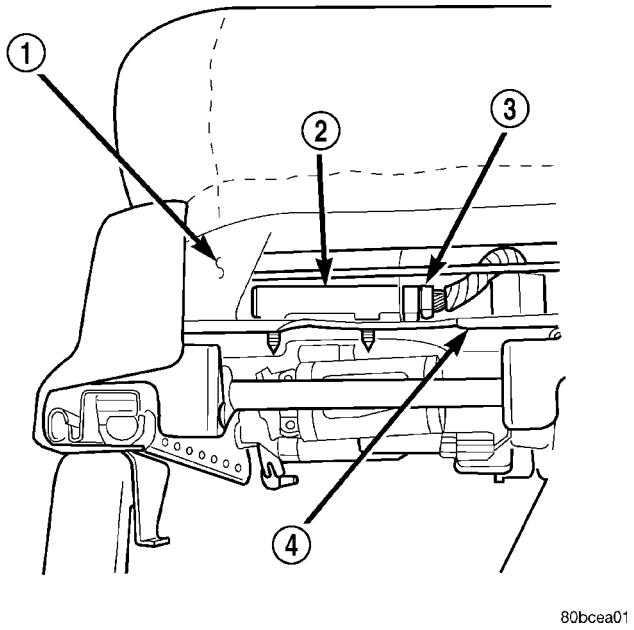

Fig. 6 Heated Seat Module Location - Typical

1 - SEAT CUSHION FRAME
2 - HEATED SEAT MODULE
3 - WIRE HARNESS CONNECTOR
4 - POWER SEAT TRACK FRONT BRACKET

One heated seat module is used per vehicle to control both front heated seats. The heated seat module (Fig. 6) is located on the driver seat cushion pan, where it is secured with two push-pin type plastic fasteners. The module is encased within a small, rectangular, molded plastic housing with a single connector receptacle that allows it to be connected to all of the required inputs and outputs through the power seat wire harness.

The heated seat module is an electronic microprocessor designed to monitor inputs and control the outputs of the heated seat system. The heated seat module is programmed to provide two levels of heating for each front seat. The Low temperature set point is about 36° C (97° F) and the High temperature set point is about 41° C (105° F). The heated seat module is also programmed to perform self-diagnosis. If the module detects a shorted or open heating element or a Negative Temperature Coefficient (NTC) heated seat sensor out of range the module will flash the heated seat switch LED's, to indicate that a problem exists with the heated seat system. (Refer to 8 - ELECTRICAL/ELECTRONIC CONTROL MODULES/MEMORY HEATED SEAT/MIRROR MODULE - DIAGNOSIS AND TESTING) for additional information.

The heated seat module cannot be adjusted or repaired. If a module is damaged or inoperative, the entire module must be replaced.

OPERATION

The heated seat module operates on battery current received through a fuse in the Junction Block (JB) on a fused ignition switch output (run-acc) circuit. The heated seat system will only operate when the ignition switch is in the On or Accessory positions. The heated seat module is grounded at all times through a two wire take out and eyelet terminal secured by a ground screw to the top of the seat crossmember under each front seat.

Inputs to the heated seat module include:

- A heated seat switch MUX circuit for each of the two heated seat switches
- Heated seat sensor inputs from the seat cushions of each front seats
- Battery current from the power seat circuit breaker in the JB received through the energized heated seat relay on two heated seat relay output circuits

Outputs from the heated seat module include:

- A battery voltage reference to the heated seat sensors on a sensor feed circuit
- A battery current feed to the two heated seat element circuits on separate heated seat driver circuits
- Separate Lo and Hi driver circuits for each of the heated seat switch Light-Emitting Diode (LED) indicator lamps

When a driver or passenger heated seat switch request signal is received by the heated seat module, the module energizes the proper switch LED indicator lamp (Lo or Hi) by pulling the LED driver circuit to ground. At the same time, the heated seat module energizes the heated seat sensor feed circuit and the sensor provides the module with a heat sense input indicating the surface temperature of the selected seat cushion. If the seat cushion surface temperature input is below the temperature set point for the selected heat mode, the heated seat module energizes an N-channel Field Effect Transistor (N-FET) within the module. The N-FET switches battery current to the heated seat elements in the selected seat cushion and back. When the heated seat sensor input indicates the correct temperature set point has been achieved, the heated seat module de-energizes the N-FET which switches off the battery current to the heated seat elements. The heated seat module will continue to cycle the N-FET as needed to maintain the selected temperature set point.

If the heated seat module detects a heated seat sensor value input that is out of range or a shorted or open heated seat element circuit, it will automat-

HEATED SEAT MODULE (Continued)

ically de-energize the N-FET and switch off the battery current to the affected heated seat elements. The heated seat module will also indicate this condition by flashing the Hi and/or Lo LED lamps in the affected heated seat switch in a prescribed sequence as a self-diagnostic feedback.

DIAGNOSIS AND TESTING - HEATED SEAT MODULE

Refer to the appropriate wiring diagrams information. The wiring information includes wiring diagrams, proper wire and connector repair procedures, further details on wire harness routing and retention, as well as pin-out and location views for the various wire harness connectors, splices and grounds.

(1) If a heated seat fails to heat and one or both of the LED indicator lamps on a heated seat switch flash, (Refer to 8 - ELECTRICAL/HEATED SEATS - DIAGNOSIS AND TESTING).

(2) Test the appropriate Heated Seat Switch, (Refer to 8 - ELECTRICAL/HEATED SEATS/ DRIVER HEATED SEAT SWITCH - DIAGNOSIS AND TESTING).

(3) Test the Heated Seat Sensor, (Refer to 8 - ELECTRICAL/HEATED SEATS/HEATED SEAT SENSOR - DIAGNOSIS AND TESTING).

(4) Test the Heated Seat Element, (Refer to 8 - ELECTRICAL/HEATED SEATS/HEATED SEAT ELEMENT - DIAGNOSIS AND TESTING).

(5) Disconnect the heated seat module connector receptacle. Using an ohmmeter, check for continuity between the **ground circuit** cavity and a good ground. If OK, go to Step 6. If not OK, repair the open ground circuit to ground as required.

(6) Place the ignition key in the RUN position. Using a voltmeter, check for voltage on the **B+ circuit** cavity. If OK, go to Step 7. If not OK, repair the open B+ circuit as required.

(7) Using an ohmmeter, check for continuity on the individual circuits between the heated seat module and the inoperative heated seat switch and elements. If OK, replace the heated seat module, (Refer to 8 - ELECTRICAL/ELECTRONIC CONTROL MODULES/MEMORY HEATED SEAT/MIRROR MODULE - REMOVAL). If not OK, repair the open or shorted circuit between the heated seat module and the inoperative heated seat switch and elements as necessary.

REMOVAL

WARNING: THERE ARE MANY SHARP METAL EDGES ON THE SEAT CUSHION FRAME AND SEAT ADJUSTER RAILS UNDER THE SEAT. WHEN PERFORMING THIS SERVICE, A LONG-SLEEVED SHIRT AND GLOVES SHOULD BE WORN IN ORDER TO AVOID UNNECESSARY CUTS AND ABRASIONS TO EXPOSED SKIN.

(1) Move the driver power seat to its full up and full rear stop positions.

(2) Disconnect and isolate the battery negative cable.

(3) Working under the seat, release the two plastic push-in fasteners from either the module or the mounting holes in the power seat cushion pan (Fig. 7).

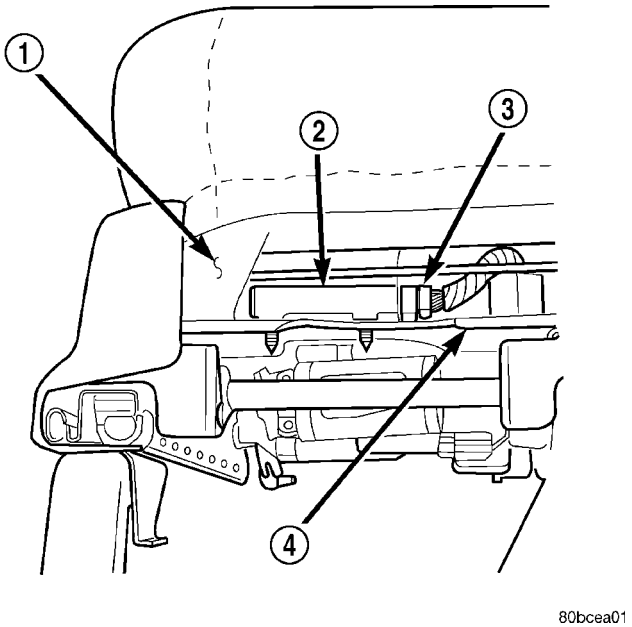

Fig. 7 Heated Seat Module Location- Typical

1 - SEAT CUSHION FRAME
2 - HEATED SEAT MODULE
3 - WIRE HARNESS CONNECTOR
4 - POWER SEAT TRACK FRONT BRACKET

(4) Disconnect the power seat wire harness connector from the heated seat module connector receptacle.

(5) Remove the heated seat module from the power seat track.

INSTALLATION

(1) If the two plastic push-in fasteners for the heated seat module were damaged during removal, install new fasteners onto the heated seat module.

(2) Reconnect the power seat wire harness connector to the heated seat module connector receptacle. Be certain that the cavities in the power seat wire harness connector are aligned with the terminals in the heated seat module connector receptacle before pushing the connector firmly into place.

(3) Install the heated seat module on the power seat cushion pan.

(4) Reconnect the battery negative cable.

POWERTRAIN CONTROL MODULE

DESCRIPTION

OPERATION - SENSOR RETURN - PCM INPUT

The sensor return circuit provides a low electrical noise ground reference for all of the systems sensors. The sensor return circuit connects to internal ground circuits within the Powertrain Control Module (PCM).

DATA BUS COMMUNICATION RECEIVE - PCM INPUT

The PCM uses the SCI communication bus to preform engine diagnostics and flash operations. The transmission side of the PCM uses the SCI communication bus to flash new software. However, diagnostics is performed via the vehicles J1850 bus for the transmission side of the PCM.

OPERATION - IGNITION SENSE - PCM INPUT

The ignition sense input informs the Powertrain Control Module (PCM) that the ignition switch is in the crank or run position.

PCM GROUND

Ground is provided through multiple pins of the PCM connector. Depending on the vehicle there may be as many as two different ground pins. There are power grounds and sensor grounds.

The power grounds are used to control the ground side relays, solenoids, ignition coil or injectors. The signal ground is used for any input that uses sensor return for ground, and the ground side of any internal processing component.

The PCM case is shielded to prevent RFI and EMI. The PCM case is grounded and must be firmly attached to a good, clean body ground.

Internally all grounds are connected together, however there is noise suppression on the sensor ground. For EMI and RFI protection the housing and cover are also grounded separately from the ground pins.

OPERATION

OPERATION

The PCM receives input signals from various switches and sensors that are referred to as PCM Inputs. Based on these inputs, the PCM adjusts various engine, transmission, and vehicle operations through devices that are referred to as PCM Outputs (Fig. 8).

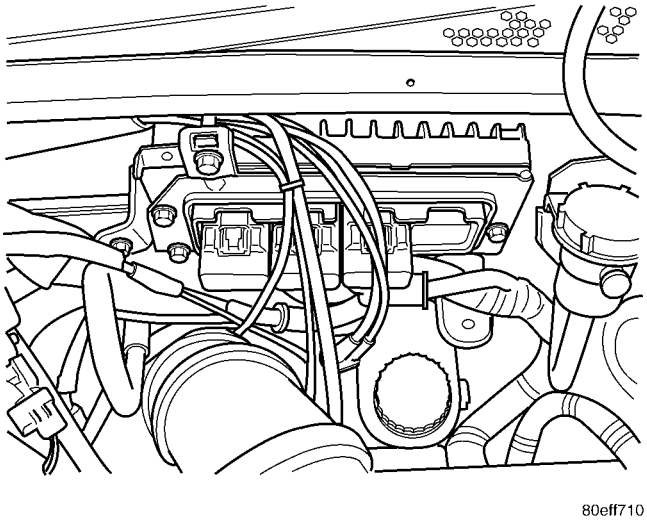

Fig. 8 PCM

NOTE: PCM Inputs:

- Air Conditioning Controls
- Ambient Air temperature Sensor
- ASD Sense
- Baro/Tip (Turbo)
- Battery Voltage
- Battery Temperature Sensor
- Brake Switch
- Camshaft Position Sensor
- Clutch Upstop Switch
- Clutch Interlock
- Crankshaft Position Sensor
- Engine Coolant Temperature Sensor
- Fuel Level Sensor (Bus message)
- Ignition Switch
- Intake Air Temperature Sensor
- J1850
- Knock Sensor (2.0, 2.4L)
- Natural Vacuum Leak Detection (NVLD)
- Manifold Absolute Pressure (MAP) Sensor
- Oil Pressure Switch
- Oxygen Sensors
- Power Steering Pressure Switch
- SCI Receive
- Speed Control Switches
- Throttle Position Sensor
- Transmission Control Relay (Switched B+)
- Transmission Input Shaft Speed Sensor
- Transmission Output Shaft Speed Sensor
- Transmission Pressure Switches (L/R, 2/4, OD)
- Transmission Range Sensor (TRS)
- Transmission Oil Temperature Sensor (Integral to TRS)
- Vehicle Speed Sensor (MTX-equipped models)

POWERTRAIN CONTROL MODULE (Continued)

NOTE: PCM Outputs:

- Air Conditioning Clutch Relay
- Auto Shutdown (ASD) Relay
- Charging Indicator Lamp (Bus Message)
- SCI Transmit
- Proportional Purge Solenoid
- EGR Solenoid
- Fuel Injectors
- Fuel Pump Relay
- Generator Field
- Idle Air Control Motor (2.0/2.4L)
- Ignition Coils
- J1850
- Malfunction Indicator (Check Engine) Lamp (Bus Message)
- Oxygen Sensors Heater Controls
- Radiator Fan Relays
- Speed Control Solenoids (2.0/2.4L)
- Transmission Control Relay
- Transmission Solenoids (LR/CC, 2/4, OD, and UD)
- Transmission PRNDL Position (to Cluster)
- Transmission Torque Reduction Request (Internal to PCM)
- Transmission Temperature (Internal to PCM and a Bus Message)
- Vehicle Speed (Manual Transmission)

Based on inputs it receives, the PCM adjusts fuel injector pulse width, idle speed, ignition spark advance, ignition coil dwell and EVAP canister purge operation. The PCM also determines the appropriate transmission shift schedule and shift points, depending on the present operating conditions and driver demand. The PCM regulates the cooling fan, air conditioning and speed control systems. The PCM changes generator charge rate by adjusting the generator field. The PCM also performs diagnostics.

The PCM adjusts injector pulse width (air-fuel ratio) based on the following inputs.

- Battery voltage
- Coolant temperature
- Exhaust gas content (oxygen sensor)
- Engine speed (crankshaft position sensor)
- Intake air temperature
- Manifold absolute pressure
- Throttle position

The PCM adjusts ignition timing based on the following inputs.

- Coolant temperature
- Engine speed (crankshaft position sensor)
- Knock sensor
- Manifold absolute pressure
- Throttle position
- Transmission gear selection (park/neutral switch)
- Intake air temperature

The PCM also adjusts engine idle speed through the idle air control motor based on the following inputs.

- Air conditioning sense
- Battery voltage
- Battery temperature
- Brake switch
- Coolant temperature
- Engine speed (crankshaft position sensor)
- Engine run time
- Manifold absolute pressure
- Power steering pressure switch
- Throttle position
- Transmission gear selection (park/neutral switch)
- Vehicle distance (speed)

The Auto Shutdown (ASD) and fuel pump relays are located in the Power Distribution Center (PDC).

The camshaft position sensor and crankshaft position sensor signals are sent to the PCM. If the PCM does not receive the signal within approximately 1 second of engine cranking, it deactivates the ASD relay and fuel pump relay. When these relays are deactivated, power is shut off from the fuel injectors, ignition coils, oxygen sensor heating elements and fuel pump.

The PCM contains a voltage converter that changes battery voltage to a regulated 5 volts direct current to power the camshaft position sensor, crankshaft position sensor, manifold absolute pressure sensor, throttle position sensor, A/C pressure switch, A/C pressure transducer, and vehicle speed sensor.

Powertrain Control Module Connectors

The PCM is an engine and transmission controller module all in one, if the vehicle is equipped with an automatic transmission. The PCM uses four wiring harness connectors to receive and send engine and transmission data. To ease assembly, the mating wiring harness connector is color-coded. Each module connector cavity has its own unique color identification stripe located on the outside of each connector cavity.

The PCM module utilizes four wiring harness connectors as described:

- Connector Cavity A is for Power & Ground (Black)
- Connector Cavity B is for Engine Side (Orange)
- Connector Cavity C is for Headlamp & Dash (White)
- Connector Cavity D is for Transmission (Green) If equipped

POWERTRAIN CONTROL MODULE (Continued)

NOTE: Connector Cavities A, B, C, And D must be connected prior to battery connection and ignition key on to avoid setting erroneous controller fault codes. It is also recommended that cavity A connector is made prior to any other connectors.

TRANSMISSION CONTROL

CLUTCH VOLUME INDEX (CVI)

An important function of the PCM is to monitor Transmission Clutch Volume Index (CVI). CVIs represent the volume of fluid needed to compress a clutch pack.

The PCM monitors gear ratio changes by monitoring the Input and Output Speed Sensors. The Input, or Turbine Speed Sensor sends an electrical signal to the PCM that represents input shaft rpm. The Output Speed Sensor provides the PCM with output shaft speed information.

By comparing the two inputs, the PCM can determine transaxle gear ratio. This is important to the CVI calculation because the PCM determines CVIs by monitoring how long it takes for a gear change to occur (Fig. 9).

Gear ratios can be determined by using the DRBIII® Scan Tool and reading the Input/Output Speed Sensor values in the “Monitors” display. Gear ratio can be obtained by dividing the Input Speed Sensor value by the Output Speed Sensor value.

For example, if the input shaft is rotating at 1000 rpm and the output shaft is rotating at 500 rpm, then the PCM can determine that the gear ratio is 2:1. In direct drive (3rd gear), the gear ratio changes to 1:1. The gear ratio changes as clutches are applied and released. By monitoring the length of time it takes for the gear ratio to change following a shift request, the PCM can determine the volume of fluid used to apply or release a friction element.

The volume of transmission fluid needed to apply the friction elements are continuously updated for adaptive controls. As friction material wears, the volume of fluid need to apply the element increases.

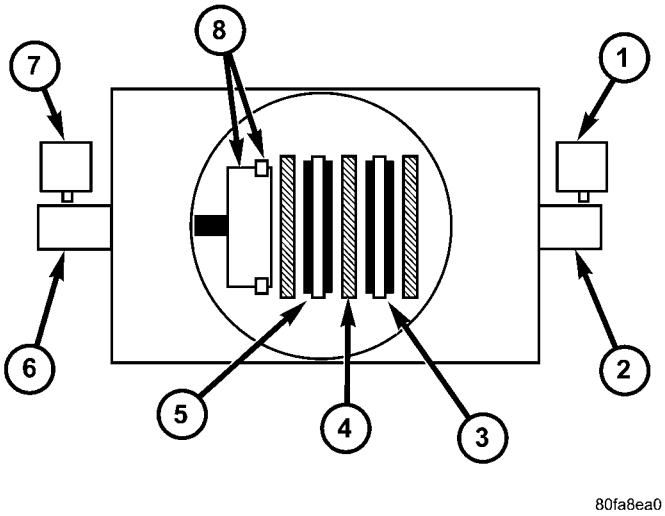

Fig. 9 Example of CVI Calculation

1 - OUTPUT SPEED SENSOR
2 - OUTPUT SHAFT
3 - CLUTCH PACK
4 - SEPARATOR PLATE
5 - FRICTION DISCS
6 - INPUT SHAFT
7 - INPUT SPEED SENSOR
8 - PISTON AND SEAL

Certain mechanical problems within the clutch assemblies (broken return springs, out of position snap rings, excessive clutch pack clearance, improper assembly, etc.) can cause inadequate or out-of-range clutch volumes. Also, defective Input/Output Speed Sensors and wiring can cause these conditions. The following chart identifies the appropriate clutch volumes and when they are monitored/updated:

CLUTCH VOLUMES				
Clutch	When Updated			Proper Clutch Volume
	Shift Sequence	Oil Temperature	Throttle Angle	
L/R	2-1 or 3-1 coast downshift	> 70°	< 5°	35 to 83
2/4	1-2 shift	> 110°	5 - 54°	20 to 77
OD	2-3 shift			48 to 150
UD	4-3 or 4-2 shift		> 5°	24 to 70

POWERTRAIN CONTROL MODULE (Continued)

TRANSMISSION SHIFT SCHEDULES

The PCM is programmed to allow it to select a variety of shift schedules. Shift schedule selection is dependent on the following:

- Shift lever position
- Throttle position
- Engine load
- Fluid temperature
- Software calibration level

As driving conditions change, the PCM appropriately adjusts the shift schedule. Refer to the following chart to determine the appropriate operation expected, depending on driving conditions.

Schedule	Condition	Expected Operation
Extreme Cold	Oil temperature at start-up below -16° F	Park, Reverse, Neutral and 2nd gear only (prevents shifting which may fail a clutch with frequent shifts)
Cold	Oil temperature at start-up above -12° F and below 36° F	– Delayed 2-3 upshift (approximately 22-31 mph) – Delayed 3-4 upshift (45-53 mph) – Early 4-3 costdown shift (approximately 30 mph) – Early 3-2 coastdown shift (approximately 17 mph) – High speed 4-2, 3-2, 2-1 kickdown shifts are prevented – No EMCC
Warm	Oil temperature at start-up above 36° F and below 80 degree F	– Normal operation (upshift, kickdowns, and coastdowns) – No EMCC
Hot	Oil temperature at start-up above 80° F	– Normal operation (upshift, kickdowns, and coastdowns) – Full EMCC, no PEMCC except to engage FEMCC (except at closed throttle at speeds above 70-83 mph)
Overheat	Oil temperature above 240° F or engine coolant temperature above 244° F	– Delayed 2-3 upshift (25-32 mph) – Delayed 3-4 upshift (41-48 mph) – 3rd gear FEMCC from 30-48 mph – 3rd gear PEMCC from 27-31 mph
Super Overheat	Oil temperature above 260° F	– All ″Overheat″ shift schedule features apply – 2nd gear PEMCC above 22 mph – Above 22 mph the torque converter will not unlock unless the throttle is closed or if a wide open throttle 2nd PEMCC to 1 kickdown is made

POWERTRAIN CONTROL MODULE (Continued)

5 VOLT SUPPLY - PCM OUTPUT

The PCM supplies 5 volts to the following sensors:
- A/C pressure transducer
- Ambient Temperature sensor
- Battery temperature
- Camshaft Position Sensor (NGC)
- Crankshaft Position Sensor (NGC)
- Engine coolant temperature sensor
- Inlet Air Temperature Sensor
- Knock sensor
- Linear EGR solenoid (if equipped)
- Manifold absolute pressure sensor
- Oil Pressure Switch
- Throttle position sensor

STANDARD PROCEDURE

STANDARD PROCEDURE - OBTAINING DIAGNOSTIC TROUBLE CODES

BULB CHECK

Key on: Bulb illuminated until vehicle starts, as long as all once per trip (readiness) monitors completed. If monitors have **not** been completed, then: Key on: bulb check for about 5 to 8 seconds, lamp then flashes if once per trip (readiness) monitors have **not** been completed until vehicle is started, then MIL is extinguished.

OBTAINING DTC'S USING SCAN TOOL

(1) Connect the scan tool to the data link (diagnostic) connector. This connector is located in the passenger compartment; at the lower edge of instrument panel; near the steering column.

(2) Turn the ignition switch on and access the "Read Fault" screen.

(3) Record all the DTC's and "freeze frame" information shown on the scan tool.

(4) To erase DTC's, use the "Erase Trouble Code" data screen on the scan tool. **Do not erase any DTC's until problems have been investigated and repairs have been performed.**

STANDARD PROCEDURE - PINION FACTOR SETTING

NOTE: This procedure must be performed if the PCM has been replaced with a NEW or replacement unit. Failure to perform this procedure will result in an inoperative or improperly calibrated speedometer.

The vehicle speed readings for the speedometer are taken from the output speed sensor. The PCM must be calibrated to the different combinations of equipment (final drive and tires) available. Pinion Factor allows the technician to set the Powertrain Control Module initial setting so that the speedometer readings will be correct. To properly read and/or reset the Pinion Factor, it is necessary to use a scan tool.

(1) Plug the scan tool into the diagnostic connector located under the instrument panel.

(2) Select the Transmission menu.

(3) Select the Miscellaneous menu.

(4) Select Pinion Factor. Then follow the instructions on the scan tool screen.

STANDARD PROCEDURE - QUICK LEARN PROCEDURE

The quick learn procedure requires the use of the DRBIII® scan tool. This program allows the PCM to recalibrate itself. This will provide the best possible transaxle operation.

NOTE: The quick learn procedure should be performed if any of the following procedures are performed:

- Transaxle Assembly Replacement
- Powertrain Control Module Replacement
- Solenoid/Pressure Switch Assembly Replacement
- Clutch Plate and/or Seal Replacement
- Valve Body Replacement or Recondition

To perform the Quick Learn Procedure, the following conditions must be met:
- The brakes must be applied
- The engine speed must be above 500 rpm
- The throttle angle (TPS) must be less than 3 degrees
- The shift lever position must stay until prompted to shift to overdrive
- The shift lever position must stay in overdrive after the Shift to Overdrive prompt until the DRBIII® indicates the procedure is complete
- The calculated oil temperature must be above 60° and below 200°

(1) Plug the DRBIII® scan tool into the diagnostic connector. The connector is located under the instrument panel.

(2) Go to the Transmission screen.

(3) Go to the Miscellaneous screen.

(4) Select Quick Learn Procedure. Follow the instructions of the DRBIII® to perform the Quick Learn Procedure.

REMOVAL

REMOVAL - 1.6L

The PCM engine control strategy prevents reduced idle speeds until after the engine operates for 320 km (200 miles). If the PCM is replaced after 320 km (200

POWERTRAIN CONTROL MODULE (Continued)

miles) of usage, update the mileage and vehicle identification number (VIN) in the new PCM. Use the DRBIII® scan tool to change the mileage and VIN in the PCM. If this step is not done a Diagnostic Trouble Code (DTC) may be set. Refer to the appropriate Powertrain Diagnostic Manual and the DRBIII® scan tool.

The PCM attaches to a bracket which attaches to the dash panel welded brackets (Fig. 10).

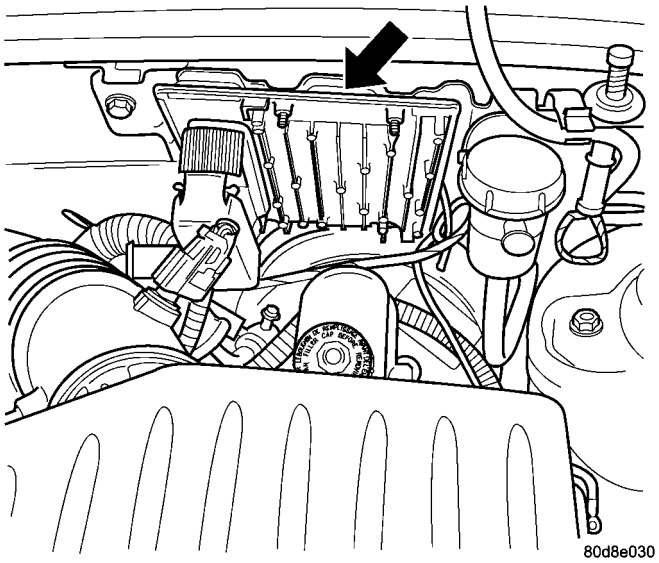

Fig. 10 PCM LOCATION

(1) Remove the air cleaner lid, disconnect the inlet air temperature sensor and makeup air hose (Fig. 11).

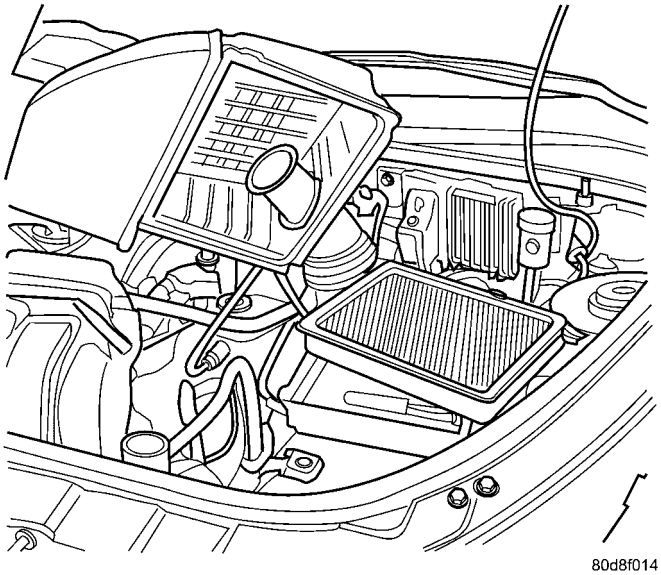

Fig. 11 AIR BOX COVER

(2) Remove the negative battery cable (Fig. 12).

(6) Remove the 3 screws from the PCM bracket to PCM (Fig. 23).

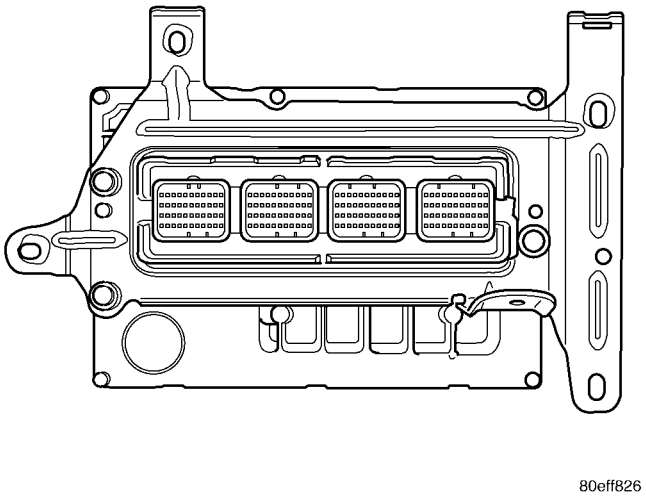

Fig. 23 PCM AND MOUNTING BRACKET

INSTALLATION

INSTALLATION - 1.6L

The PCM engine control strategy prevents reduced idle speeds until after the engine operates for 320 km (200 miles). If the PCM is replaced after 320 km (200 miles) of usage, update the mileage and vehicle identification number (VIN) in the new PCM. Use the DRBIII® scan tool to change the millage and VIN in the PCM. If this step is not done a Diagnostic Trouble Code (DTC) may be set. Refer to the appropriate Powertrain Diagnostic Manual and the DRBIII® scan tool.

The PCM attaches to a bracket which attaches to the dash panel welded bracket (Fig. 10).

(1) Install PCM. Tighten mounting nuts to 10.7 N·m (95 ins. lbs.) (Fig. 15).

(2) Attach electrical connectors to PCM (Fig. 14).

(3) Lock the PCM connector (Fig. 13).

(4) Install the negative battery cable (Fig. 12).

(5) Install the air cleaner lid, connect the inlet air temperature sensor and makeup air hose (Fig. 11).

INSTALLATION - 2.0, 2.4, and 2.4L TURBO

(1) Install the PCM bracket and 3 screws to the PCM (Fig. 23) and tighten to 11.8 N·m (105 in. lbs.).

(2) Install the PCM and bracket assembly and locate the bracket on the tab (Fig. 21).

(3) Install the 3 mounting screws to the PCM mounting bracket (Fig. 20) and tighten to 10.7 N·m (95 in. lbs.).

NOTE: The electrical connector for the PCM are COLOR Coded.

(4) Connect and lock the 3 or 4 electrical connectors to the Powertrain Control Module (PCM) (Fig. 18).

(5) Relocate and install the clutch reservoir (Fig. 19).

(6) Connect the negative battery cable.

SENTRY KEY IMMOBILIZER MODULE

DESCRIPTION

The Sentry Key Immobilizer Module (SKIM) (Fig. 24) contains a Radio Frequency (RF) transceiver and a microprocessor. The SKIM retains in memory the ID numbers of any Sentry Key that is programmed to it. The maximum number of keys that may be programmed to each module is eight (8). The SKIM also communicates over the PCI bus with the Powertrain Control Module (PCM), the instrument cluster, and the DRB III® scan tool. The SKIM transmits and receives RF signals through a tuned antenna enclosed within a molded plastic ring formation that is integral to the SKIM housing. When the SKIM is properly installed on the steering column, the antenna ring fits snugly around the circumference of the ignition lock cylinder housing (Fig. 25). If this ring is not mounted properly, communication problems may arise in the form of transponder-related faults.

For added system security, each SKIM is programmed with a unique ″Secret Key″ code. This code is stored in memory and is sent over the PCI bus to the PCM and to each key that is programmed to

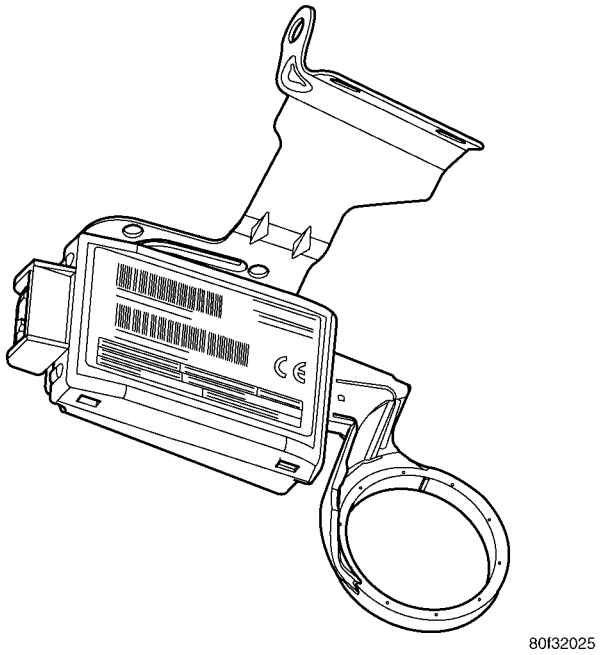

Fig. 24 SENTRY KEY IMMOBILIZER MODULE

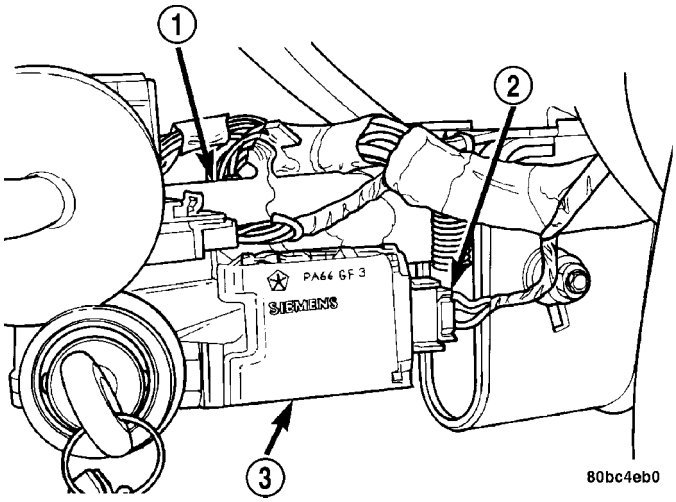

Fig. 25 SENTRY KEY IMMOBILIZER MODULE LOCATION

1 - STEERING COLUMN
2 - SKIM ELECTRICAL CONNECTOR
3 - SKIM

work with the vehicle. The ″Secret Key″ code is therefore a common element found in all components of the Sentry Key Immobilizer System (SKIS). In the event that a SKIM replacement is required, the ″Secret Key″ code can be restored from the PCM by following the SKIM replacement procedure found in the DRB III® scan tool. Proper completion of this task will allow the existing ignition keys to be reprogrammed. Therefore, new keys will NOT be needed. In the event that the original ″Secret Key″ code can not be recovered, new ignition keys will be required. The DRB III® scan tool will alert the technician if key replacement is necessary. Another security code, called a PIN, is used to gain secured access to the SKIM for service. The SKIM also stores in its memory the Vehicle Identification Number (VIN), which it learns through a bus message from the PCM during initialization. The SKIS scrambles the information that is communicated between its components in order to reduce the possibility of unauthorized SKIM access and/or disabling.

OPERATION

When the ignition switch is moved to the RUN position, the SKIM transmits an RF signal to the transponder in the ignition key. The SKIM then waits for a response RF signal from the transponder in the key. If the response received identifies the key as valid, the SKIM sends a ″valid key″ message to the PCM over the PCI bus. If the response received identifies the key as invalid or no response is received from the transponder in the ignition key, the SKIM sends an ″invalid key″ message to the PCM. The PCM will enable or disable engine operation based upon the status of the SKIM messages. It is important to note that the default condition in the PCM is ″invalid key.″ Therefore, if no response is received by the PCM, the engine will be immobilized after two (2) seconds of running.

The SKIM also sends indicator light status messages to the instrument cluster to tell that module how to operate the light. This may consist of turning the light ON for a three (3) second bulb test when the ignition switch is first turned to the ON position. It is also the method used to turn the light ON solid or to flash it after the indicator light test is complete to signify a fault in the SKIS. If the light comes ON and stays ON solid after the indicator light test, this signifies that the SKIM has detected a system malfunction and/or that the SKIS has become inoperative. If the SKIM detects an invalid key OR a key-related fault exists, the indicator light will flash following the indicator light test. The SKIM may also request an audible chime if the customer key programming feature is available and the procedure is being utilized. Refer to Electrical, Vehicle Theft Security, Transponder Key, Standard Procedure - Sentry Key Immobilizer System Transponder programming.

STANDARD PROCEDURE - SENTRY KEY IMMOBILIZER SYSTEM INITIALIZATION

The Sentry Key Immobilizer System (SKIS) initialization should be performed following a Sentry Key Immobilizer Module (SKIM) replacement. It can be summarized as follows:

(1) Obtain the vehicle's unique four-digit PIN assigned to its original SKIM from the vehicle owner,

SENTRY KEY IMMOBILIZER MODULE (Continued)

the vehicle's invoice, or from Chrysler's Customer Center.

(2) Using a DRB III® scan tool, select "Theft Alarm," "SKIM," "Miscellaneous," and then "SKIM Module Replaced."

(a) Enter Secured Access Mode using the unique four-digit PIN.

(b) Program the vehicle's VIN number into the SKIM's memory.

(c) Program the country code into the SKIM's memory (for North America, choose US or domestic).

(d) The vehicle's unique Secret Key data will be retrieved from the PCM automatically. If this data is corrupt or not present, you will be prompted to cut new keys for this vehicle.

(3) Program all customer keys into the SKIM's memory.

This process will require that the SKIM to be in the Secured Access Mode. The PIN must be entered into the DRB III® scan tool before the SKIM will enter the Secured Access Mode. Once entered, Secured Access Mode shall be active until 60 seconds after the last command requiring secured access was received and acknowledged.

Two exceptions to this rule are:

- When you have used the 'erase all keys' command **OR**
- When you have just programmed a new key.

If either of these functions are performed successfully while in the Secured Access Mode, this mode will be exited immediately following the function.

NOTE: If a PCM is replaced, the unique 'Secret Key' data must be transferred from the SKIM to the new PCM using the PCM replacement procedure. This procedure requires the Secured Access Mode as well and can be found in the DRB III® scan tool.

REMOVAL

(1) Disconnect and isolate the battery negative remote cable.

(2) Remove Lower Instrument Panel Cover. Refer to Body, Instrument Panel, Lower Instrument Panel Cover, Removal.

(3) Remove the steering column upper and lower shrouds. Refer to Steering, Column, Column Shroud, Removal.

(4) Disengage the steering column wire harness from the Sentry Key Immobilizer Module (SKIM) (Fig. 26).

(5) Remove the two screws securing the SKIM to the top of the steering column (Fig. 26).

(6) Rotate the SKIM and its mounting bracket upwards and then to the side away from the steering column to slide the SKIM antenna ring from around the ignition switch lock cylinder housing (Fig. 26).

(7) Remove the SKIM from the vehicle.

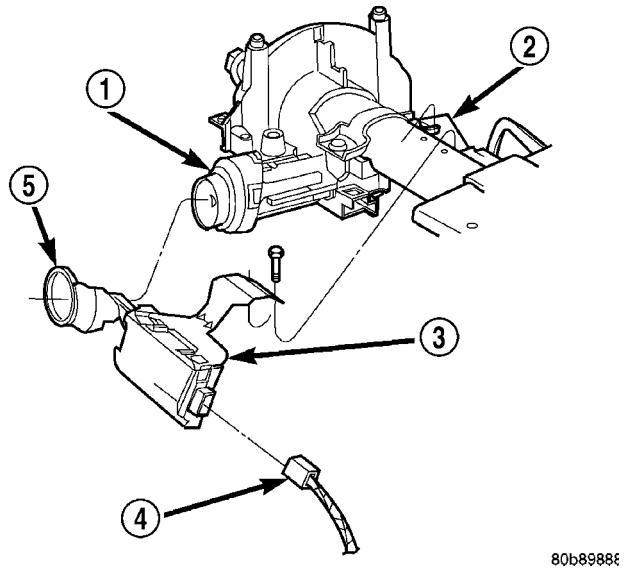

Fig. 26 SENTRY KEY IMMOBILIZER MODULE (SKIM) REMOVE/INSTALL

1 - IGNITION KEY CYLINDER
2 - STEERING COLUMN
3 - SENTRY KEY IMMOBILIZER MODULE (SKIM)
4 - SKIM CONNECTOR
5 - SKIM ANTENNA

INSTALLATION

NOTE: If the SKIM is replaced with a new unit, a DRB III® scan tool MUST be used to initialize the new SKIM and to program at least two Sentry Key transponders (Refer to 8 - ELECTRICAL/ELECTRONIC CONTROL MODULES/SENTRY KEY IMMOBILIZER MODULE - STANDARD PROCEDURE).

(1) Place the SKIM into position.

(2) Rotate the SKIM and its mounting bracket downwards and then to the side towards the steering column (Fig. 26).

(3) Install the two screws securing the SKIM to the top of the steering column (Fig. 26).

(4) Engage the steering column wire harness to the Sentry Key Immobilizer Module (SKIM) (Fig. 26).

(5) Install the steering column upper and lower shrouds. Refer to Steering, Column, Column Shroud, Installation.

(6) Install the Lower Instrument Panel Cover. Refer to Body, Instrument Panel, Lower Instrument Panel Cover, Installation.

(7) Connect the battery negative cable.

BATTERY SYSTEM

DESCRIPTION

A single 12-volt battery is standard factory-installed equipment on this model. All of the components of the battery system are located within the engine compartment of the vehicle, except on vehicles equipped with a diesel engine. Vehicles equipped with a diesel engine have the battery mounted under the passenger front seat. The battery system for this vehicle covers the following related components, which are covered in further detail later in this section of the service manual:

- **Battery** - The storage battery provides a reliable means of storing a renewable source of electrical energy within the vehicle.
- **Battery Cables** - The battery cables connect the positive and negative charged battery terminal posts to the vehicle electrical system.
- **Battery Holddown** - The battery holddown hardware secures the battery in the battery tray.
- **Battery Thermal Guard** - The battery thermal guard insulates the battery to protect it from engine compartment temperature extremes.
- **Battery Tray** - The battery tray provides a secure mounting location in the vehicle for the battery and an anchor point for the battery holddown hardware (some models) and battery temperature sensor (if equipped).
- **Battery Tray Support Bracket** - The battery tray support bracket provides additional support for the battery and battery tray.

For battery system maintenance schedules and jump starting procedures, see the owner's manual in the vehicle glove box. Optionally, refer to the Lubrication and Maintenance section of this manual for the recommended battery maintenance schedules and for the proper battery jump starting procedure. While battery charging can be considered a maintenance procedure, the battery charging procedure and related information are located later in this section of this service manual. This was done because the battery must be fully-charged before any battery system diagnosis or testing procedures can be performed.

OPERATION

The battery system is designed to provide a safe, efficient, reliable and mobile means of delivering and storing electrical energy. This electrical energy is required to operate the engine starting system, as well as to operate many of the other vehicle accessory systems for limited durations while the engine and/or the charging system are not operating. The battery system is also designed to provide a reserve of electrical energy to supplement the charging system for short durations while the engine is running and the electrical current demands of the vehicle that exceed the output of the charging system. In addition to delivering, and storing electrical energy for the vehicle, the battery system serves as a capacitor and voltage stabilizer for the vehicle electrical system. It absorbs most abnormal or transient voltages caused by the switching of any of the electrical components or circuits in the vehicle.

DIAGNOSIS AND TESTING - BATTERY SYSTEM

The battery, starting, and charging systems in the vehicle operate with one another and must be tested as a complete system. In order for the engine to start and the battery to maintain its charge properly, all of the components that are used in these systems must perform within specifications. It is important that the battery, starting, and charging systems be thoroughly tested and inspected any time a battery needs to be charged or replaced. The cause of abnormal battery discharge, overcharging or early battery failure must be diagnosed and corrected before a battery is replaced and before a vehicle is returned to service. The service information for these systems has been separated within this service manual to make it easier to locate the specific information you are seeking. However, when attempting to diagnose any of these systems, it is important that you keep their interdependency in mind.

The diagnostic procedures used for the battery, starting, and charging systems include the most basic conventional diagnostic methods, to the more sophisticated On-Board Diagnostics (OBD) built into the Powertrain Control Module (PCM). Use of an induction-type milliampere ammeter, a volt/ohmmeter, a battery charger, a carbon pile rheostat (load tester) and a 12-volt test lamp may be required. All OBD-sensed systems are monitored by the PCM. Each monitored circuit is assigned a Diagnostic Trouble Code (DTC). The PCM will store a DTC in electronic memory for any failure it detects. Refer to Charging System for the proper charging system on-board diagnostic test procedures.

MICRO 420 BATTERY TESTER

The Micro 420 automotive battery tester is designed to help the dealership technicians diagnose the cause of a defective battery. Follow the instruction manual supplied with the tester to properly diagnose a vehicle. If the instruction manual is not available refer to the standard procedure in this section, which includes the directions for using the Micro 420 battery tester.

BATTERY SYSTEM (Continued)

BATTERY SYSTEM DIAGNOSIS		
CONDITION	POSSIBLE CAUSES	CORRECTION
THE BATTERY SEEMS WEAK OR DEAD WHEN ATTEMPTING TO START THE ENGINE.	1. The electrical system ignition-off draw is excessive.	1. Refer to the IGNITION-OFF DRAW TEST Standard Procedure for the proper test procedures. Repair the excessive ignition-off draw, as required.
	2. The charging system is faulty.	2. Determine if the charging system is performing to specifications. Refer to Charging System for additional charging system diagnosis and testing procedures. Repair the faulty charging system, as required.
	3. The battery is discharged.	3. Determine the battery state-of-charge using the Micro 420 battery tester. Refer to the Standard Procedures in this section for additional test procedures. Charge the faulty battery, as required.
	4. The battery terminal connections are loose or corroded.	4. Refer to Battery Cables for the proper battery cable diagnosis and testing procedures. Clean and tighten the battery terminal connections, as required.
	5. The battery has an incorrect size or rating for this vehicle.	5. Refer to Battery System Specifications for the proper size and rating. Replace an incorrect battery, as required.
	6. The battery is faulty.	6. Test the battery using the Micro 420 battery tester. Refer to the Standard Procedures in this section for additional test procedures. Replace the faulty battery, as required.
	7. The starting system is faulty.	7. Determine if the starting system is performing to specifications. Refer to Starting System for the proper starting system diagnosis and testing procedures. Repair the faulty starting system, as required.
	8. The battery is physically damaged.	8. Inspect the battery for loose terminal posts or a cracked and leaking case. Replace the damaged battery, as required.

BATTERY SYSTEM (Continued)

BATTERY SYSTEM DIAGNOSIS		
CONDITION	POSSIBLE CAUSES	CORRECTION
THE BATTERY STATE OF CHARGE CANNOT BE MAINTAINED.	1. The battery has an incorrect size or rating for this vehicle.	1. Refer to Battery System Specifications for the proper specifications. Replace an incorrect battery, as required.
	2. The battery terminal connections are loose or corroded.	2. Refer to Battery Cable for the proper cable diagnosis and testing procedures. Clean and tighten the battery terminal connections, as required.
	3. The electrical system ignition-off draw is excessive.	3. Refer to the IGNITION-OFF DRAW TEST Standard Procedure for the proper test procedures. Repair the faulty electrical system, as required.
	4. The battery is faulty.	4. Test the battery using the Micro 420 battery tester. Refer to Standard Procedures for additional test procedures. Replace the faulty battery, as required.
	5. The starting system is faulty.	5. Determine if the starting system is performing to specifications. Refer to Starting System for the proper starting system diagnosis and testing procedures. Repair the faulty starting system, as required.
	6. The charging system is faulty.	6. Determine if the charging system is performing to specifications. Refer to Charging System for charging system diagnosis and testing procedures. Repair the faulty charging system, as required.
	7. Electrical loads exceed the output of the charging system.	7. Inspect the vehicle for aftermarket electrical equipment which might cause excessive electrical loads.
	8. Slow driving or prolonged idling with high-amperage draw loads in use.	8. Advise the vehicle operator, as required.
THE BATTERY WILL NOT ACCEPT A CHARGE.	1. The battery is faulty.	1. Test the battery using the Micro 420 battery tester.. Charge or replace the faulty battery, as required.

ABNORMAL BATTERY DISCHARGING

Any of the following conditions can result in abnormal battery discharging:

1. A faulty or incorrect charging system component. Refer to Charging System for additional charging system diagnosis and testing procedures.
2. A faulty or incorrect battery. Use Micro 420 tester and refer to Battery System for additional battery diagnosis and testing procedures.
3. A faulty circuit or component causing excessive ignition-off draw.
4. Electrical loads that exceed the output of the charging system. This can be due to equipment installed after manufacture, or repeated short trip use.
5. A faulty or incorrect starting system component. Refer to Starting System for the proper starting system diagnosis and testing procedures.
6. Corroded or loose battery posts and/or terminal clamps.
7. Slow driving speeds (heavy traffic conditions) or prolonged idling, with high-amperage draw loads in use.

BATTERY SYSTEM (Continued)

CLEANING

The following information details the recommended cleaning procedures for the battery and related components. In addition to the maintenance schedules found in this service manual and the owner's manual, it is recommended that these procedures be performed any time the battery or related components must be removed for vehicle service.

(1) Clean the battery cable terminal clamps of all corrosion. Remove any corrosion using a wire brush or a post and terminal cleaning tool, and a sodium bicarbonate (baking soda) and warm water cleaning solution (Fig. 1).

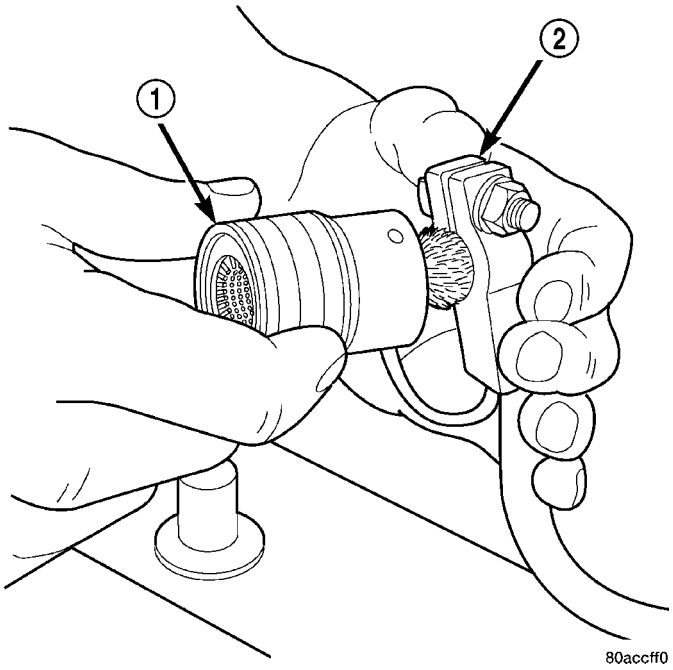

Fig. 1 Clean Battery Cable Terminal Clamp - Typical

1 - TERMINAL BRUSH
2 - BATTERY CABLE

(2) Clean the battery tray and battery holddown hardware of all corrosion. Remove any corrosion using a wire brush and a sodium bicarbonate (baking soda) and warm water cleaning solution. Paint any exposed bare metal.

(3) If the removed battery is to be reinstalled, clean the outside of the battery case and the top cover with a sodium bicarbonate (baking soda) and warm water cleaning solution using a stiff bristle parts cleaning brush to remove any acid film (Fig. 2). Rinse the battery with clean water. Ensure that the cleaning solution does not enter the battery cells through the vent holes. If the battery is being replaced, refer to Battery System Specifications for the factory-installed battery specifications. Confirm that the replacement battery is the correct size and has the correct ratings for the vehicle.

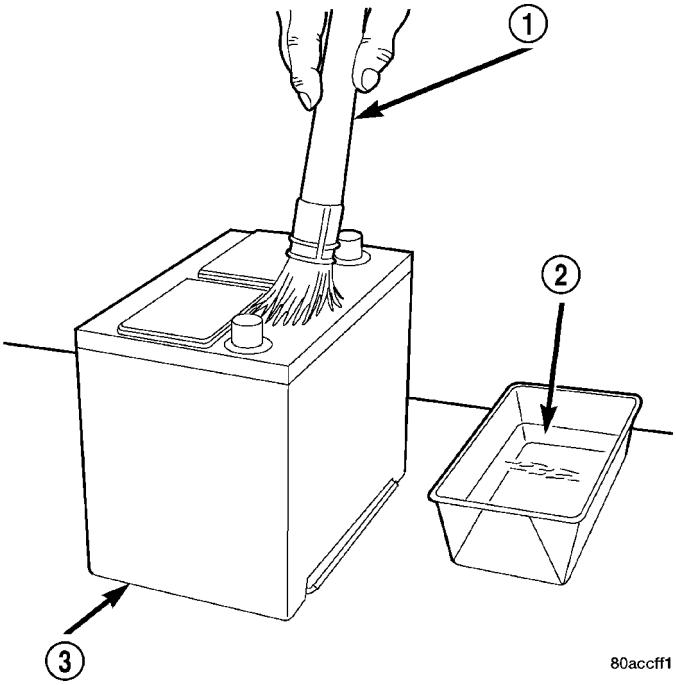

Fig. 2 Clean Battery - Typical

1 - CLEANING BRUSH
2 - WARM WATER AND BAKING SODA SOLUTION
3 - BATTERY

(4) Clean the battery thermal guard with a sodium bicarbonate (baking soda) and warm water cleaning solution using a stiff bristle parts cleaning brush to remove any acid film.

(5) Clean any corrosion from the battery terminal posts with a wire brush or a post and terminal cleaner, and a sodium bicarbonate (baking soda) and warm water cleaning solution (Fig. 3).

INSPECTION

The following information details the recommended inspection procedures for the battery and related components. In addition to the maintenance schedules found in this service manual and the owner's manual, it is recommended that these procedures be performed any time the battery or related components must be removed for vehicle service.

(1) Inspect the battery cable terminal clamps for damage. Replace any battery cable that has a damaged or deformed terminal clamp.

(2) Inspect the battery tray and battery holddown hardware for damage. Replace any damaged parts.

(3) Slide the thermal guard off of the battery case (if equipped). Inspect the battery case for cracks or other damage that could result in electrolyte leaks. Also, check the battery terminal posts for looseness. Batteries with damaged cases or loose terminal posts must be replaced.

(4) Inspect the battery thermal guard for tears, cracks, deformation or other damage (if equipped).

BATTERY SYSTEM (Continued)

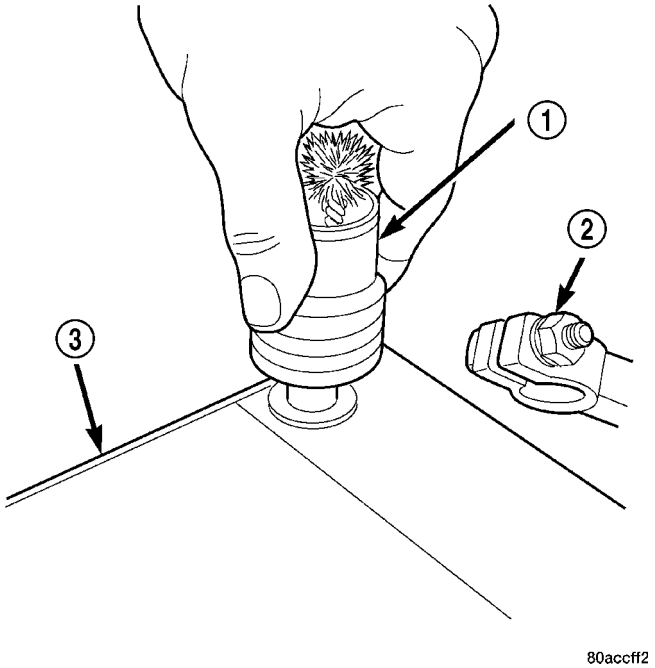

Fig. 3 Clean Battery Terminal Post - Typical

1 - TERMINAL BRUSH
2 - BATTERY CABLE
3 - BATTERY

Replace any battery thermal guard that has been damaged.

(5) Inspect the battery built-in test indicator sight glass (if equipped) for an indication of the battery condition. If the battery is discharged, charge as required. Refer to Standard Procedures for detailed instructions.

SPECIFICATIONS

SPECIFICATIONS

The battery Group Size number, the Cold Cranking Amperage (CCA) rating, and the Reserve Capacity (RC) rating or Ampere-Hours (AH) rating can be found on the original equipment battery label. Be certain that a replacement battery has the correct Group Size number, as well as CCA, and RC or AH ratings that equal or exceed the original equipment specification for the vehicle being serviced. Battery sizes and ratings are discussed in more detail below.

NOTE: Vehicles equipped with a diesel engine utilize a unique battery. The specifications for this battery may differ from the standards shown here. Refer to the battery manufacturer for detailed specifications.

- **Group Size** - The outside dimensions and terminal placement of the battery conform to standards established by the Battery Council International (BCI). Each battery is assigned a BCI Group Size number to help identify a correctly-sized replacement.
- **Cold Cranking Amperage** - The Cold Cranking Amperage (CCA) rating specifies how much current (in amperes) the battery can deliver for thirty seconds at -18° C (0° F). Terminal voltage must not fall below 7.2 volts during or after the thirty second discharge period. The CCA required is generally higher as engine displacement increases, depending also upon the starter current draw requirements.
- **Reserve Capacity** - The Reserve Capacity (RC) rating specifies the time (in minutes) it takes for battery terminal voltage to fall below 10.5 volts, at a discharge rate of 25 amperes. RC is determined with the battery fully-charged at 26.7° C (80° F). This rating estimates how long the battery might last after a charging system failure, under minimum electrical load.
- **Ampere-Hours** - The Ampere-Hours (AH) rating specifies the current (in amperes) that a battery can deliver steadily for twenty hours, with the voltage in the battery not falling below 10.5 volts. This rating is also sometimes identified as the twenty-hour discharge rating.

BATTERY CLASSIFICATIONS & RATINGS

BATTERY

DESCRIPTION

There are two different batteries available on this model. Vehicles equipped with a diesel engine utilize a spiral wound plate designed battery with recombination technology. This is a maintenance-free battery that is capable of delivering more power than a conventional battery. This additional power is required by a diesel engine during cold cranking. Vehicles equipped with a gasoline engine utilize a conventional battery. Refer to the following information for detailed differences and descriptions of these two batteries.

SPIRAL PLATE BATTERY - DIESEL ENGINE

Spiral plate technology takes the elements of traditional batteries - lead and sulfuric acid - to the next level. By tightly winding layers of spiral grids and acid-permeated vitreous separators into cells, the manufacturer has developed a battery with more power and service life than conventional batteries the same size. The spiral plate battery (Fig. 4) is completely, permanently sealed. Through gas recombination, hydrogen and oxygen within the battery are captured during normal charging and reunited to form the water within the electrolyte, eliminating the need to add distilled water. Therefore, these batteries have non-removable battery vent caps. Water **cannot** be added to this battery.

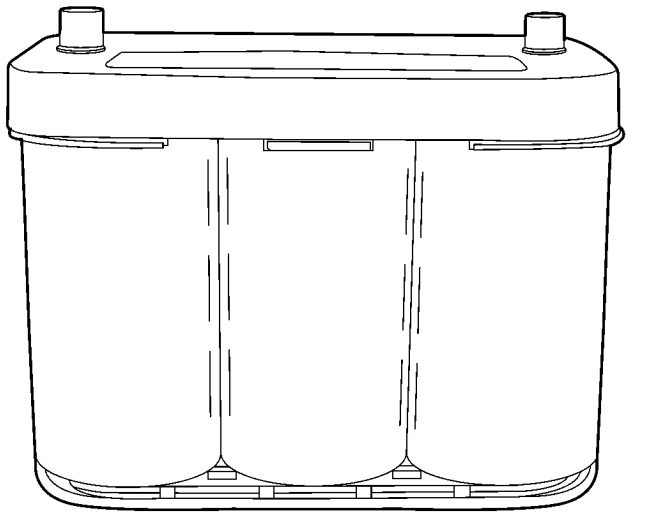

Fig. 4 PG Spiral Plate Battery

The acid inside an spiral plate battery is bound within the vitreous separators, ending the threat of acid leaks. This feature allows the battery to be installed in any position anywhere in the vehicle.

Spiral plate technology is the process by which the plates holding the active material in the battery are wound tightly in coils instead of hanging flat, like conventional batteries. This design has a lower internal resistance and also increases the active material surface area.

WARNING: NEVER EXCEED 14.4 VOLTS WHEN CHARGING A SPIRAL PLATE BATTERY. PERSONAL INJURY AND/OR BATTERY DAMAGE MAY RESULT.

BATTERY (Continued)

Due to the maintanance-free design, distilled water cannot be added to this battery. Therefore, if more than 14.4 volts are used during the spiral plate battery charging process, water vapor can be exhausted through the pressure-sensitive battery vents and lost for good. This can permanently damage the spiral plate battery. Never exceed 14.4 volts when charging a spiral plate battery. Personal injury and/or battery damage may result.

CONVENTIONAL BATTERY - GASOLINE ENGINE

Low-maintenance conventional batteries are used on vehicles equipped with a gasoline engine, these batteries have non-removable battery cell caps. Under normal service, the composition of this battery reduces gassing and water loss at normal charge rates.

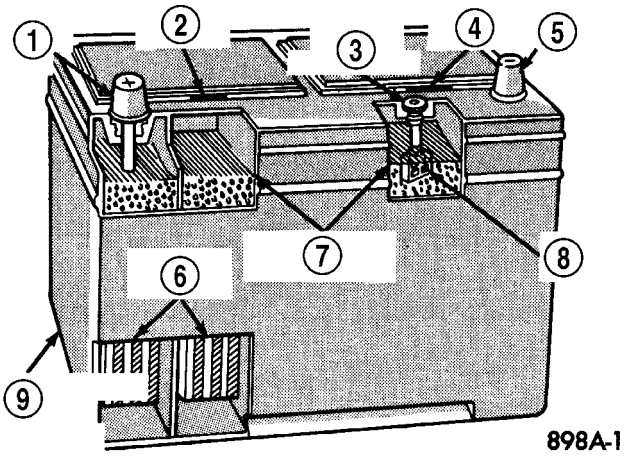

Fig. 5 Conventional Battery

1 - POSITIVE POST
2 - VENT
3 - TEST INDICATOR (IF EQUIPPED)
4 - VENT
5 - NEGATIVE POST
6 - PLATE GROUPS
7 - ELECTROLYTE LEVEL
8 - GREEN BALL
9 - BATTERY

Conventional batteries (Fig. 5) are made up of six individual cells that are connected in series. Each cell contains positive charged plate groups made of lead oxide, and negatively charged plate groups made of sponge lead. The plates are submerged in a sulfuric acid and water solution called electrolyte.

Both batteries are used to store electrical energy potential in a chemical form. When an electrical load is applied to the battery terminals, an electrochemical reaction occurs within the battery. This reaction causes the battery to discharge electrical current.

OPERATION

The battery is designed to store electrical energy in a chemical form. When an electrical load is applied to the terminals of the battery, an electrochemical reaction occurs. This reaction causes the battery to discharge electrical current from its terminals. As the battery discharges, a gradual chemical change takes place within each cell. The chemical changes within the battery are caused by the movement of excess or free electrons between the positive and negative plate groups. This movement of electrons produces a flow of electrical current through the load device attached to the battery terminals.

The battery is vented to release excess hydrogen gas that is created when the battery is being charged or discharged. However, even with these vents, hydrogen gas can collect in or around the battery. If hydrogen gas is exposed to flame or sparks, it may ignite. If the battery is equipped with removable cell caps, add distilled water whenever the electrolyte level is below the top of the plates. If the battery cell caps cannot be removed, the battery must be replaced if the electrolyte level becomes low.

DIAGNOSIS AND TESTING - BATTERY

The battery must be completely charged and the terminals should be properly cleaned and inspected before diagnostic procedures are performed. Refer to Battery System Cleaning for the proper cleaning procedures, and Battery System Inspection for the proper battery inspection procedures. Refer to Standard Procedures for the proper battery charging procedures.

MICRO 420 BATTERY TESTER

The Micro 420 automotive battery tester is designed to help the dealership technicians diagnose the cause of a defective battery. Follow the instruction manual supplied with the tester to properly diagnose a vehicle. If the instruction manual is not available refer to the standard procedure in this section, which includes the directions for using the Micro 420 battery tester.

WARNING: IF THE BATTERY SHOWS SIGNS OF FREEZING, LEAKING OR LOOSE POSTS, DO NOT TEST, ASSIST-BOOST, OR CHARGE. THE BATTERY MAY ARC INTERNALLY AND EXPLODE. PERSONAL INJURY AND/OR VEHICLE DAMAGE MAY RESULT.

WARNING: EXPLOSIVE HYDROGEN GAS FORMS IN AND AROUND THE BATTERY. DO NOT SMOKE, USE FLAME, OR CREATE SPARKS NEAR THE BATTERY. PERSONAL INJURY AND/OR VEHICLE DAMAGE MAY RESULT.

BATTERY (Continued)

WARNING: THE BATTERY CONTAINS SULFURIC ACID, WHICH IS POISONOUS AND CAUSTIC. AVOID CONTACT WITH THE SKIN, EYES, OR CLOTHING. IN THE EVENT OF CONTACT, FLUSH WITH WATER AND CALL A PHYSICIAN IMMEDIATELY. KEEP OUT OF THE REACH OF CHILDREN.

A battery that will not accept a charge is faulty, and must be replaced. Further testing is not required. A fully-charged battery must be tested to determine its cranking capacity. A battery that is fully-charged, but does not pass the Micro 420 or load test, is faulty and must be replaced.

NOTE: Completely discharged batteries may take several hours to accept a charge. Refer to Standard Procedures for the proper battery charging procedures.

STANDARD PROCEDURE

STANDARD PROCEDURE - SPIRAL PLATE BATTERY CHARGING

Vehicles equipped with a diesel engine utilize a unique spiral plate battery. This battery has a maximum charging voltage that must not be exceeded in order to restore the battery to its full potential, failure to use the following spiral plate battery charging procedure could result in damage to the battery or personal injury.

Battery charging is the means by which the battery can be restored to its full voltage potential. A battery is fully-charged when:

- Micro 420 battery tester indicates battery is OK.
- Open-circuit voltage of the battery is 12.65 volts or above.
- Battery passes Load Test multiple times.

WARNING: IF THE BATTERY SHOWS SIGNS OF FREEZING, LEAKING, LOOSE POSTS OR LOW ELECTROLYTE LEVEL, DO NOT TEST, ASSIST-BOOST, OR CHARGE. THE BATTERY MAY ARC INTERNALLY AND EXPLODE. PERSONAL INJURY AND/OR VEHICLE DAMAGE MAY RESULT.

CAUTION: Always disconnect and isolate the battery negative cable before charging a battery. Charge the battery directly at the battery terminals. Do not exceed 14.4 volts while charging a battery.

CAUTION: The battery should not be hot to the touch. If the battery feels hot to the touch, turn off the charger and let the battery cool before continuing the charging operation. Damage to the battery may result.

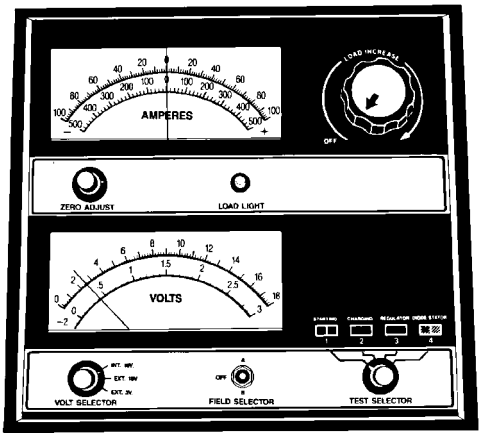
After the battery has been charged to 12.6 volts or greater, perform a load test to determine the battery cranking capacity. Refer to Battery Diagnosis and Testing for the proper battery test procedures. If the battery will endure a load test, return the battery to service. If the battery will not pass a load test, it is faulty and must be replaced.

Clean and inspect the battery hold downs, tray, terminals, posts, and top before completing battery service. Refer to Battery System Cleaning for the proper battery system cleaning procedures, and Battery System Inspection for the proper battery system inspection procedures.

CHARGING A COMPLETELY DISCHARGED BATTERY – SPIRAL PLATE BATTERY

The following procedure should be used to recharge a completely discharged battery. Unless this procedure is properly followed, a good battery may be needlessly replaced.

(1) Measure the voltage at the battery posts with a voltmeter, accurate to 1/10 (0.10) volt (Fig. 6). Refer to Battery Removal and Installation for access instructions. If the reading is below ten volts, the battery charging current will be low. It could take several hours before the battery accepts a current greater than a few milliamperes. Such low current may not be detectable on the ammeters built into many battery chargers.



898A-12

Fig. 6 Voltmeter - Typical

BATTERY (Continued)

(2) Disconnect and isolate the battery negative cable. Connect the battery charger leads. Some battery chargers are equipped with polarity-sensing circuitry. This circuitry protects the battery charger and the battery from being damaged if they are improperly connected. If the battery state-of-charge is too low for the polarity-sensing circuitry to detect, the battery charger will not operate. This makes it appear that the battery will not accept charging current. See the instructions provided by the manufacturer of the battery charger for details on how to bypass the polarity-sensing circuitry.

(3) Battery chargers vary in the amount of voltage and current they provide. The amount of time required for a battery to accept measurable charging current at various voltages is shown in the Charge Rate Table. If the charging current is still not measurable at the end of the charging time, the battery is faulty and must be replaced. If the charging current is measurable during the charging time, the battery may be good and the charging should be completed in the normal manner.

SPIRAL-PLATE BATTERY CHARGE RATE TABLE	
Voltage	Minutes
14.4 volts maximum	up to 10 minutes
13.0 to 14 volts	up to 20 minutes
12.9 volts or less	up to 30 minutes

CHARGING TIME REQUIRED

The time required to charge a battery will vary, depending upon the following factors:

- **Battery Capacity** - A completely discharged heavy-duty battery requires twice the charging time of a small capacity battery.
- **Temperature** - A longer time will be needed to charge a battery at -18° C (0° F) than at 27° C (80° F). When a fast battery charger is connected to a cold battery, the current accepted by the battery will be very low at first. As the battery warms, it will accept a higher charging current rate (amperage).
- **Charger Capacity** - A battery charger that supplies only five amperes will require a longer charging time. A battery charger that supplies eight amperes will require a shorter charging time.
- **State-Of-Charge** - A completely discharged battery requires more charging time than a partially discharged battery. Electrolyte is nearly pure water in a completely discharged battery. At first, the charging current (amperage) will be low. As the battery charges, the specific gravity of the electrolyte will gradually rise.

The Battery Charging Time Table gives an indication of the time required to charge a typical battery at room temperature based upon the battery state-of-charge and the charger capacity.

SPIRAL-PLATE BATTERY CHARGING TIME TABLE		
Charging Amperage	5 Amps	8 Amps
Open Circuit Voltage	Hours Charging @ 21° C (70° F)	
12.25 to 12.49	6 hours	3 hours
12.00 to 12.24	10 hours	5 hours
10.00 to 11.99	14 hours	7 hours
Below 10.00	18 hours	9 hours

STANDARD PROCEDURE - CONVENTIONAL BATTERY CHARGING

Vehicles equipped with a diesel engine utilize a unique spiral plate battery. This battery has a maximum charging voltage that must be used in order to restore the battery to its full potential, failure to use the spiral plate battery charging procedure could result in damage to the battery or personal injury.

Battery charging is the means by which the battery can be restored to its full voltage potential. A battery is fully-charged when:

- Micro 420 battery tester indicates battery is OK.
- Open-circuit voltage of the battery is 12.65 volts or above.
- Battery passes Load Test multiple times.

WARNING: IF THE BATTERY SHOWS SIGNS OF FREEZING, LEAKING, LOOSE POSTS, DO NOT TEST, ASSIST-BOOST, OR CHARGE. THE BATTERY MAY ARC INTERNALLY AND EXPLODE. PERSONAL INJURY AND/OR VEHICLE DAMAGE MAY RESULT.

WARNING: EXPLOSIVE HYDROGEN GAS FORMS IN AND AROUND THE BATTERY. DO NOT SMOKE, USE FLAME, OR CREATE SPARKS NEAR THE BATTERY. PERSONAL INJURY AND/OR VEHICLE DAMAGE MAY RESULT.

WARNING: THE BATTERY CONTAINS SULFURIC ACID, WHICH IS POISONOUS AND CAUSTIC. AVOID CONTACT WITH THE SKIN, EYES, OR CLOTHING. IN THE EVENT OF CONTACT, FLUSH WITH WATER AND CALL A PHYSICIAN IMMEDIATELY. KEEP OUT OF THE REACH OF CHILDREN.

BATTERY (Continued)

WARNING: IF THE BATTERY IS EQUIPPED WITH REMOVABLE CELL CAPS, BE CERTAIN THAT EACH OF THE CELL CAPS IS IN PLACE AND TIGHT BEFORE THE BATTERY IS RETURNED TO SERVICE. PERSONAL INJURY AND/OR VEHICLE DAMAGE MAY RESULT FROM LOOSE OR MISSING CELL CAPS.

CAUTION: Always disconnect and isolate the battery negative cable before charging a battery. Do not exceed sixteen volts while charging a battery. Damage to the vehicle electrical system components may result.

CAUTION: Battery electrolyte will bubble inside the battery case during normal battery charging. Electrolyte boiling or being discharged from the battery vents indicates a battery overcharging condition. Immediately reduce the charging rate or turn off the charger to evaluate the battery condition. Damage to the battery may result from overcharging.

CAUTION: The battery should not be hot to the touch. If the battery feels hot to the touch, turn off the charger and let the battery cool before continuing the charging operation. Damage to the battery may result.

After the battery has been charged to an open-circuit voltage reading of 12.4 volts or greater, retest the battery with the Micro 420 tester or perform a load test to determine the battery cranking capacity. Refer to Standard Procedures for the proper battery load test procedures. If the battery will pass a load test, return the battery to service. If the battery will not pass a load test, it is faulty and must be replaced.

Clean and inspect the battery hold downs, tray, terminals, posts, and top before completing battery service. Refer to Battery System Cleaning for the proper battery system cleaning procedures, and Battery System Inspection for the proper battery system inspection procedures.

CHARGING A COMPLETELY DISCHARGED CONVENTIONAL BATTERY

The following procedure should be used to recharge a completely discharged battery. Unless this procedure is properly followed, a good battery may be needlessly replaced.

(1) Measure the voltage at the battery posts with a voltmeter, accurate to 1/10 (0.10) volt (Fig. 7). If the reading is below ten volts, the battery charging current will be low. It could take some time before the battery accepts a current greater than a few milliamperes. Such low current may not be detectable on the ammeters built into many battery chargers.

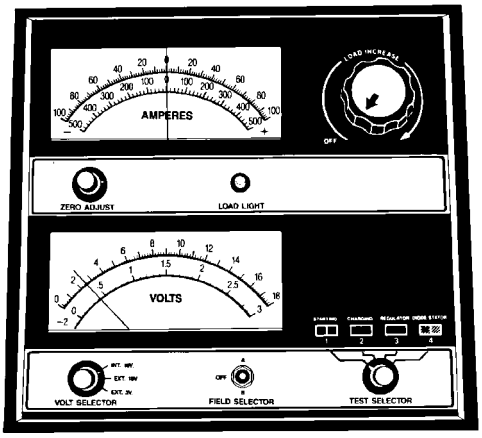


Fig. 7 Voltmeter - Typical

(2) Disconnect and isolate the battery negative cable. Connect the battery charger leads. Some battery chargers are equipped with polarity-sensing circuitry. This circuitry protects the battery charger and the battery from being damaged if they are improperly connected. If the battery state-of-charge is too low for the polarity-sensing circuitry to detect, the battery charger will not operate. This makes it appear that the battery will not accept charging current. See the instructions provided by the manufacturer of the battery charger for details on how to bypass the polarity-sensing circuitry.

(3) Battery chargers vary in the amount of voltage and current they provide. The amount of time required for a battery to accept measurable charging current at various voltages is shown in the Charge Rate Table. If the charging current is still not measurable at the end of the charging time, the battery is faulty and must be replaced. If the charging current is measurable during the charging time, the battery may be good and the charging should be completed in the normal manner.

CONVENTIONAL BATTERY CHARGE RATE TABLE	
Voltage	Minutes
16.0 volts maximum	up to 10 min.
14.0 to 15.9 volts	up to 20 min.
13.9 volts or less	up to 30 min.

CHARGING TIME REQUIRED

The time required to charge a battery will vary, depending upon the following factors:

- **Battery Capacity** - A completely discharged heavy-duty battery requires twice the charging time of a small capacity battery.

BATTERY (Continued)

• **Temperature** - A longer time will be needed to charge a battery at -18° C (0° F) than at 27° C (80° F). When a fast battery charger is connected to a cold battery, the current accepted by the battery will be very low at first. As the battery warms, it will accept a higher charging current rate (amperage).

• **Charger Capacity** - A battery charger that supplies only five amperes will require a longer charging time. A battery charger that supplies twenty amperes or more will require a shorter charging time.

• **State-Of-Charge** - A completely discharged battery requires more charging time than a partially discharged battery. Electrolyte is nearly pure water in a completely discharged battery. At first, the charging current (amperage) will be low. As the battery charges, the specific gravity of the electrolyte will gradually rise.

The Conventional Battery Charging Time Table gives an indication of the time required to charge a typical battery at room temperature based upon the battery state-of-charge and the charger capacity.

CONVENTIONAL BATTERY CHARGING TIME TABLE			
Charging Amperage	5 Amps	10 Amps	20 Amps
Open Circuit Voltage	Hours Charging @ 21° C (70° F)		
12.25 to 12.49	6 hours	3 hours	1.5 hours
12.00 to 12.24	10 hours	5 hours	2.5 hours
10.00 to 11.99	14 hours	7 hours	3.5 hours
Below 10.00	18 hours	9 hours	4.5 hours

STANDARD PROCEDURE - USING MICRO 420 BATTERY TESTER

Always use the Micro 420 Instruction Manual that was supplied with the tester as a reference. If the Instruction Manual is not available the following procedure can be used:

WARNING: ALWAYS WEAR APPROPRIATE EYE PROTECTION AND USE EXTREME CAUTION WHEN WORKING WITH BATTERIES.

BATTERY TESTING

(1) If testing the battery OUT-OF-VEHICLE, clean the battery terminals with a wire brush before testing. If the battery is equipped with side post terminals, install and tighten the supplied lead terminal stud adapters. Do not use steel bolts. Failure to properly install the stud adapters, or using stud adapters that are dirty or worn-out may result in false test readings.

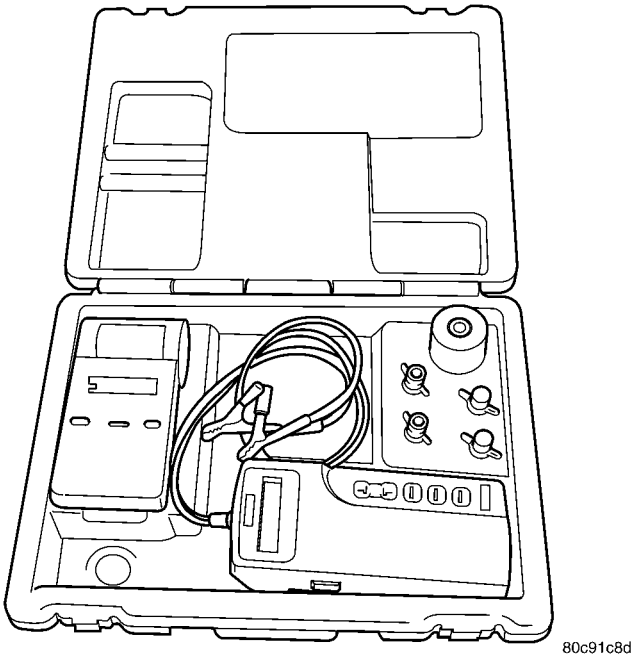

Fig. 8 Micro 420 Battery Tester

(2) If testing the battery IN-THE-VEHICLE, make certain all of the vehicle accessory loads are OFF, including the ignition. **The preferred test position is at the battery terminal**. If the battery is not accessible, you may test using both the positive and negative jumper posts. Select TESTING AT JUMPER POST when connecting to that location.

(3) Connect the tester (Fig. 8) to the battery or jumper posts, the red clamp to positive (+) and the black clamp to negative (–).

NOTE: Multiple batteries connected in parallel must have the ground cable disconnected to perform a battery test. Failure to disconnect may result in false battery test readings.

NOTE: When testing the battery in a PT Cruiser, always test at the battery terminals

(4) Using the ARROW key select **in** or **out** of vehicle testing and press ENTER to make a selection.

(5) If not selected, choose the Cold Cranking Amp (CCA) battery rating. Or select the appropriate battery rating for your area (see menu). The tester will then run its self programmed test of the battery and display the results. Refer to the test result table noted below.

BATTERY (Continued)

CAUTION: If REPLACE BATTERY is the result of the test, this may mean a poor connection between the vehicle's cables and battery exists. After disconnecting the vehicle's battery cables from the battery, retest the battery using the OUT-OF-VEHICLE test before replacing.

(6) While viewing the battery test result, press the CODE button and the tester will prompt you for the last 4 digits of the VIN. Use the UP/DOWN arrow buttons to scroll to the correct character; then press ENTER to select and move to the next digit. Then press the ENTER button to view the SERVICE CODE. Pressing the CODE button a second time will return you to the test results.

BATTERY TEST RESULTS	
GOOD BATTERY	Return to service
GOOD - RECHARGE	Fully charge battery and return to service
CHARGE & RETEST	Fully charge battery and retest battery
REPLACE BATTERY	Replace the battery and retest complete system
BAD-CELL REPLACE	Replace the battery and retest complete system

NOTE: The SERVICE CODE is required on every warranty claim submitted for battery replacement.

STANDARD PROCEDURE - OPEN-CIRCUIT VOLTAGE TEST

A battery open-circuit voltage (no load) test will show the approximate state-of-charge of a battery.

Before proceeding with this test, completely charge the battery (Refer to 8 - ELECTRICAL/BATTERY SYSTEM/BATTERY - STANDARD PROCEDURE).

(1) Before measuring the open-circuit voltage, the surface charge must be removed from the battery. Turn on the headlamps for fifteen seconds, then allow up to five minutes for the battery voltage to stabilize.

(2) Disconnect and isolate both battery cables, negative cable first.

(3) Using a voltmeter connected to the battery posts (see the instructions provided by the manufacturer of the voltmeter), measure the open-circuit voltage (Fig. 9).

See the Open-Circuit Voltage Table. This voltage reading will indicate the battery state-of-charge, but will not reveal its cranking capacity. If a battery has an open-circuit voltage reading of 12.4 volts or greater, it may be load tested to reveal its cranking capacity.

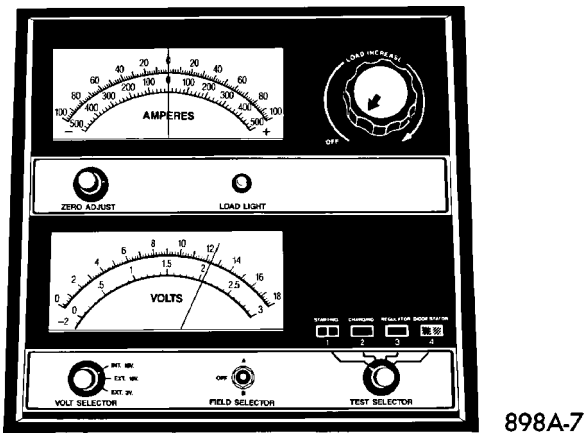

Fig. 9 Testing Open-Circuit Voltage - Typical

OPEN CIRCUIT VOLTAGE TABLE	
Open Circuit Voltage	Charge Percentage
11.7 volts or less	0%
12.0 volts	25%
12.2 volts	50%
12.4 volts	75%
12.6 volts or more	100%

STANDARD PROCEDURE - IGNITION-OFF DRAW TEST

The term Ignition-Off Draw (IOD) identifies a normal condition where power is being drained from the battery with the ignition switch in the Off position. A normal vehicle electrical system will draw from five to thirty-five milliamperes (0.005 to 0.035 ampere) with the ignition switch in the Off position, and all non-ignition controlled circuits in proper working order. Up to thirty-five milliamperes are needed to enable the memory functions for the Powertrain Control Module (PCM), digital clock, electronically tuned radio, and other modules which may vary with the vehicle equipment.

A vehicle that has not been operated for approximately twenty days, may discharge the battery to an inadequate level. When a vehicle will not be used for twenty days or more (stored), remove the IOD fuse from the Power Distribution Center (PDC). This will reduce battery discharging.

Excessive IOD can be caused by:

- Electrical items left on.
- Faulty or improperly adjusted switches.
- Faulty or shorted electronic modules and components.
- An internally shorted generator.
- Intermittent shorts in the wiring.

If the IOD is over thirty-five milliamperes, the problem must be found and corrected before replacing a battery. In most cases, the battery can be

BATTERY (Continued)

charged and returned to service after the excessive IOD condition has been corrected.

(1) Verify that all electrical accessories are off. Turn off all lamps, remove the ignition key, and close all doors. If the vehicle is equipped with an illuminated entry system or an electronically tuned radio, allow the electronic timer function of these systems to automatically shut off (time out). This may take up to three minutes.

(2) Determine that the underhood lamp is operating properly, then disconnect the lamp wire harness connector or remove the lamp bulb.

(3) Disconnect the battery negative cable.

(4) Set an electronic digital multi-meter to its highest amperage scale. Connect the multi-meter between the disconnected battery negative cable terminal clamp and the battery negative terminal post. Make sure that the doors remain closed so that the illuminated entry system is not activated. The multi-meter amperage reading may remain high for up to three minutes, or may not give any reading at all while set in the highest amperage scale, depending upon the electrical equipment in the vehicle. The multi-meter leads must be securely clamped to the battery negative cable terminal clamp and the battery negative terminal post. If continuity between the battery negative terminal post and the negative cable terminal clamp is lost during any part of the IOD test, the electronic timer function will be activated and all of the tests will have to be repeated.

(5) After about three minutes, the high-amperage IOD reading on the multi-meter should become very low or nonexistent, depending upon the electrical equipment in the vehicle. If the amperage reading remains high, remove and replace each fuse or circuit breaker in the Power Distribution Center (PDC) and then in the Junction Block (JB), one at a time until the amperage reading becomes very low, or nonexistent. Refer to the appropriate wiring information in this service manual for complete PDC and JB fuse, circuit breaker, and circuit identification. This will isolate each circuit and identify the circuit that is the source of the high-amperage IOD. If the amperage reading remains high after removing and replacing each fuse and circuit breaker, disconnect the wire harness from the generator. If the amperage reading now becomes very low or nonexistent, refer to Charging System for the proper charging system diagnosis and testing procedures. After the high-amperage IOD has been corrected, switch the multi-meter to progressively lower amperage scales and, if necessary, repeat the fuse and circuit breaker remove-and-replace process to identify and correct all sources of excessive IOD. It is now safe to select the lowest milliampere scale of the multi-meter to check the low-amperage IOD.

CAUTION: Do not open any doors, or turn on any electrical accessories with the lowest milliampere scale selected, or the multi-meter may be damaged.

(6) Observe the multi-meter reading. The low-amperage IOD should not exceed thirty-five milliamperes (0.035 ampere). If the current draw exceeds thirty-five milliamperes, isolate each circuit using the fuse and circuit breaker remove-and-replace process in Step 5. The multi-meter reading will drop to within the acceptable limit when the source of the excessive current draw is disconnected. Repair this circuit as required; whether a wiring short, incorrect switch adjustment, or a component failure is at fault.

REMOVAL

REMOVAL - GASOLINE ENGINE

WARNING:
TO PROTECT THE HANDS FROM BATTERY ACID, A SUITABLE PAIR OF HEAVY DUTY RUBBER GLOVES, NOT THE HOUSEHOLD TYPE, SHOULD BE WORN WHEN REMOVING OR SERVICING A BATTERY. SAFETY GLASSES ALSO SHOULD BE WORN.

(1) Make sure ignition switch is in OFF position and all accessories are OFF.

(2) Open hood.

(3) Remove the air cleaner housing(Refer to 9 - ENGINE/AIR INTAKE SYSTEM/AIR CLEANER HOUSING - REMOVAL).

(4) Disconnect and isolate the battery negative cable then the positive cable.

(5) Loosen bolt and retainer that holds the battery down to the tray (Fig. 10) or (Fig. 11).

(6) Lift battery out of battery tray and remove from vehicle.

(7) Remove thermal guard (if equipped) from battery.

REMOVAL - DIESEL ENGINE

(1) Make sure ignition switch is in OFF position and all accessories are OFF.

(2) Open the passenger door.

(3) Position passenger seat to the full rear location.

(4) Remove the two screws from the seat front trim panel.

(5) Lift trim panel to disengage the lower tabs from the lower mounting slots and set aside.

(6) Disconnect and isolate the battery negative cable.

BATTERY (Continued)

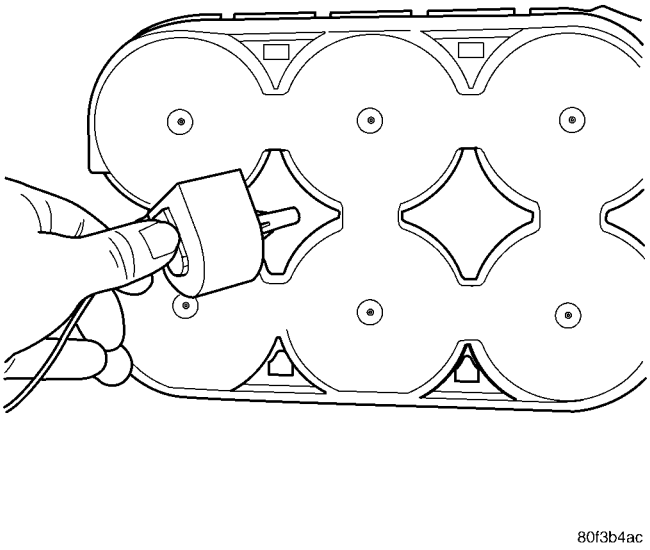

Fig. 13 Removing Battery Temperature Sensor

BATTERY (Continued)

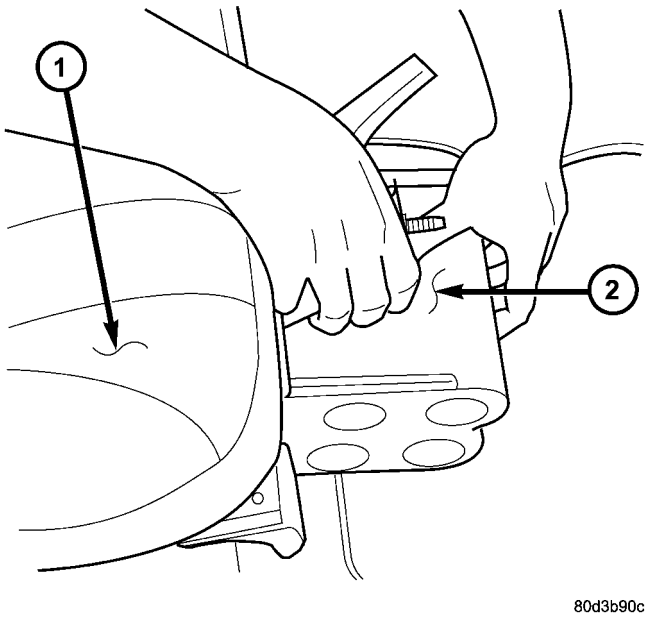

Fig. 14 Battery Removal

1 - Passenger Seat
2 - Spiral-Plate Battery

(10) Lift the battery retaining strap and pull the battery forward (Fig. 14), in front of the passenger seat.

(11) Disconnect and isolate the battery positive cable. Note the position of the battery positive cable for installation reference.

(12) Remove the battery from the vehicle.

WARNING: DO NOT USE A CONVENTIONAL LEAD-ACID BATTERY IN PLACE OF THE FACTORY EQUIPPED SPIRAL-PLATE BATTERY. FAILURE TO USE A SEALED SPIRAL-PLATE BATTERY COULD RESULT IN ACID BEING RELEASED INSIDE THE PASSENGER COMPARTMENT AND PERSONAL INJURY.

INSTALLATION

INSTALLATION - GASOLINE ENGINE

When replacing battery, the thermal guard MUST be transferred to the new battery (if equipped).

(1) Install battery in vehicle making sure that the thermal guard (if equipped) is present and battery is properly positioned on battery tray.

(2) Install battery hold down clamp, making sure that it is properly positioned on battery. Torque clamp to 110 in. lbs. ± 20 in. lbs.

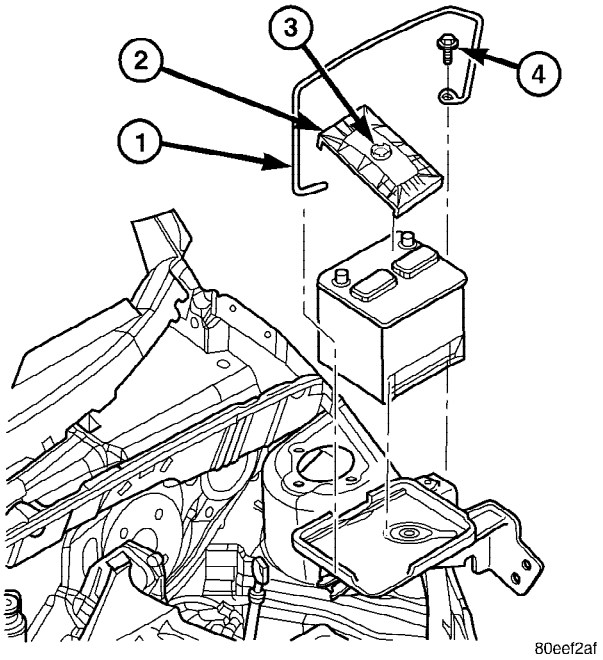

Fig. 15 Battery Remove/Install - Turbo Gasoline Engine Only

1 - HOLD DOWN ROD
2 - HOLD DOWN RETAINER
3 - NON CORROSIVE SPACERS FOR SERVICE BATTERY
4 - BOLT

CAUTION: Vehicles equipped with the turbocharged engine use a unique battery hold down. If the replacement battery is not identical, in size to the original, it may be necessary to use non-corrosive spacers on top of the hold down retainer (Fig. 15) to properly secure the battery in the battery tray.

(3) Install battery cables on battery posts. Install battery positive cable first.

(4) Torque clamp nuts to 110 in. lbs. ± 20 in. lbs.

(5) Install air cleaner housing (Refer to 9 - ENGINE/AIR INTAKE SYSTEM/AIR CLEANER HOUSING - INSTALLATION).

(6) Close hood.

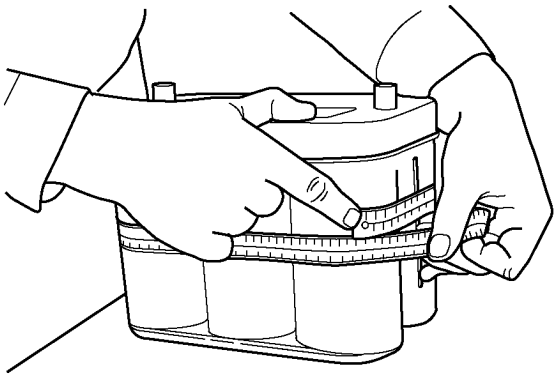
(7) Verify operation of vehicle and systems.

INSTALLATION - DIESEL ENGINE

WARNING: DO NOT USE A CONVENTIONAL LEAD-ACID BATTERY IN PLACE OF THE FACTORY EQUIPPED SPIRAL-PLATE BATTERY. FAILURE TO INSTALL A SEALED SPIRAL-PLATE BATTERY COULD RESULT IN ACID BEING RELEASED INSIDE THE PASSENGER COMPARTMENT AND PERSONAL INJURY.

BATTERY (Continued)

CAUTION: The battery must be securely fastened in the battery tray. Some Spiral-Plate batteries may be slightly different in size, if compared to the original factory installed battery. Measure the circumference of the replacement battery with a flexible tape measure as shown (Fig. 16).



811899d3

Fig. 16 Measuring Circumference of Replacement Battery

(1) Position the battery in the vehicle.
(2) Connect the battery positive cable.

WARNING: THE POSITIVE BATTERY CABLE MUST BE CORRECTLY POSITIONED ON THE BATTERY POST (Fig. 19). FAILURE TO INSTALL THE CABLE CORRECTLY COULD RESULT IN SERIOUS PERSONAL INJURY OR VEHICLE DAMAGE.

(3) Lift the battery hold down strap and slide the battery in its tray far enough to install the battery temperature sensor. Install the battery temperature sensor (Fig. 20).

(4) Slide the battery all the way into its tray and install the bolt. Torque to 30 ft. lbs. ±10 ft. lbs. Make certain the battery is securely held in place, you should not be able to move the battery in any direction using normal hand force.

(5) Clip the vent tubing assembly on the battery hold down strap.

(6) Connect the vent tube assembly (Fig. 18) or (Fig. 17).

WARNING: BE CERTAIN TO PROPERLY CONNECT THE BATTERY VENT SYSTEM. FAILURE TO DO SO COULD RESULT IN EXPLOSIVE/CAUSTIC FUMES BEING RELEASED INSIDE THE VEHICLES PASSENGER COMPARTMENT. REPLACE ANY PART OF THE VENT SYSTEM IF IT SHOWS ANY SIGNS OF WEAR, CRACKING, COLLAPSING, PUNCTURE OR ANY OTHER FORM OF IMPERFECTION.

(7) Connect the battery negative cable.
(8) Install the seat front trim panel.
(9) Install the two screws in the seat front trim panel.
(10) Close the passenger door.
(11) Verify operation of vehicle and systems.

BATTERY HOLDDOWN

DESCRIPTION

The battery holddown includes a bolt and a holddown bracket/rod. On gasoline engine equipped vehicles, the battery holddown bracket bolts directly to the battery tray (Fig. 21) and when installed properly meshes with the battery case to form a secure and stable battery holddown assembly. On diesel engine equipped vehicles, the battery holddown and battery are located under the passenger front seat.

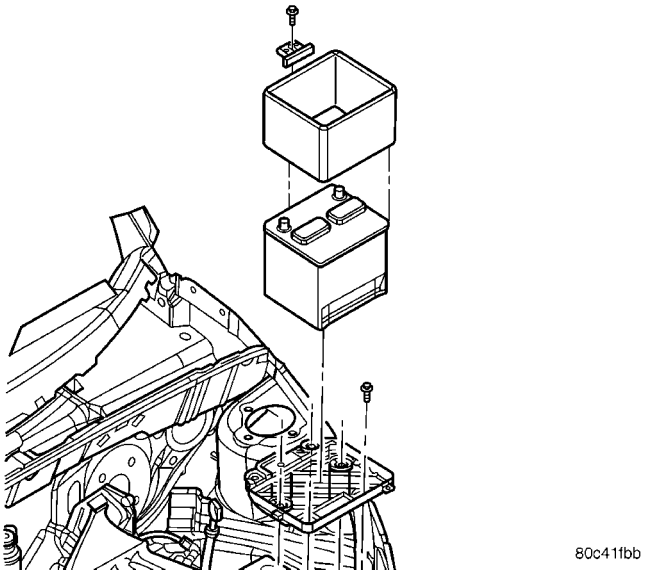

Fig. 21 Conventional Battery Holddown - Gasoline Engine Only

When installing a battery into the battery tray, it is important that the hold down hardware is properly installed and that the fasteners are tightened to the proper specifications. Improper hold down fastener tightness, whether too loose or too tight, can result in damage to the battery, the vehicle, or both.

CAUTION: Never operate a vehicle without a battery holddown device properly installed. Damage to the vehicle, components and battery could result.

OPERATION

The battery holddown secures the battery in the battery tray. This holddown is designed to prevent battery movement during the most extreme vehicle

BATTERY HOLDDOWN (Continued)

operation conditions. Periodic removal and lubrication of the battery holddown hardware is recommended to prevent hardware seizure at a later date.

REMOVAL

(1) Disconnect and isolate the negative battery cable or remote negative battery post.

(2) On gasoline engine vehicles, remove the air cleaner housing (Refer to 9 - ENGINE/AIR INTAKE SYSTEM/AIR CLEANER HOUSING - REMOVAL).

(3) On diesel engine equipped vehicles, remove the front passengers seat.

(4) Remove the battery hold down retaining bolt(s).

(5) Remove the battery hold down from the vehicle.

INSTALLATION

(1) Install the battery hold down in the vehicle.

(2) On gasoline engine equipped vehicles, install the battery. Refer to the procedure in this section of the manual for detailed instructions.

(3) On gasoline engine equipped vehicles, install the air cleaner housing (Refer to 9 - ENGINE/AIR INTAKE SYSTEM/AIR CLEANER HOUSING - INSTALLATION).

(4) On diesel engine equipped vehicles, install the passenger front seat.

(5) On diesel engine equipped vehicles, install the battery. Refer to the procedure in this section of the manual for detailed instructions.

(6) Connect the negative battery cable.

BATTERY CABLES

DESCRIPTION

The battery cables are large gauge, stranded copper wires sheathed within a heavy plastic or synthetic rubber insulating jacket. The wire used in the battery cables combines excellent flexibility and reliability with high electrical current carrying capacity. The battery cables feature a clamping type female battery terminal made of stamped sheet metal that is die cast onto one end of the battery cable wire. A pinch-bolt and nut are installed at the open end of the female battery terminal clamp. Large eyelet type terminals are crimped onto the opposite end of the battery cable wire and then soldered. The battery positive cable wires have a red insulating jacket to provide visual identification and feature a larger female battery terminal clamp to allow connection to the larger battery positive terminal post. The battery negative cable wires have a black insulating jacket and a smaller female battery terminal clamp.

Both the battery positive and negative cables are available for service replacement only as a unit with the battery wire harness, which may include portions of the wiring circuits for the generator and other components on some models.

OPERATION

The battery cables connect the battery terminal posts to the vehicle electrical system. These cables also provide a path back to the battery for electrical current generated by the charging system for restoring the voltage potential of the battery. The female battery terminal clamps on the ends of the battery cable wires provide a strong and reliable connection of the battery cable to the battery terminal posts. The terminal pinch bolts allow the female terminal clamps to be tightened around the male terminal posts on the top of the battery. The eyelet terminals secured to the opposite ends of the battery cable wires from the female battery terminal clamps provide secure and reliable connection of the battery cables to the vehicle electrical system.

One wire has an eyelet terminal that connects the battery positive cable to the B(+) terminal stud of the Power Distribution Center (PDC), and the other wire has an eyelet terminal that connects the battery positive cable to the B(+) terminal stud of the engine starter motor solenoid. The battery negative cable terminal clamp has one wire as an eyelet terminal that connects the battery negative cable to the vehicle powertrain through a ground connection, typically on the engine cylinder block.

DIAGNOSIS AND TESTING - BATTERY CABLES

A voltage drop test will determine if there is excessive resistance in the battery cable terminal connections or the battery cable. If excessive resistance is found in the battery cable connections, the connection point should be disassembled, cleaned of all corrosion or foreign material, then reassembled. Following reassembly, check the voltage drop for the battery cable connection and the battery cable again to confirm repair.

When performing the voltage drop test, it is important to remember that the voltage drop is giving an indication of the resistance between the two points at which the voltmeter probes are attached. **EXAMPLE:** When testing the resistance of the battery positive cable, touch the voltmeter leads to the battery positive cable terminal clamp and to the battery positive cable eyelet terminal at the starter solenoid B(+) terminal stud. If you probe the battery positive terminal post and the battery positive cable eyelet terminal at the starter solenoid B(+) terminal stud, you are reading the combined voltage drop in the battery positive cable terminal clamp-to-terminal post connection and the battery positive cable.

BATTERY CABLES (Continued)

VOLTAGE DROP TEST

The following operation will require a voltmeter accurate to 1/10 (0.10) volt. Before performing this test, be certain that the following procedures are accomplished:

- The battery is fully-charged and load tested. Refer to Standard Procedures for the proper battery charging and load test procedures.
- Fully engage the parking brake.
- If the vehicle is equipped with an automatic transmission, place the gearshift selector lever in the Park position. If the vehicle is equipped with a manual transmission, place the gearshift selector lever in the Neutral position and block the clutch pedal in the fully depressed position.
- Verify that all lamps and accessories are turned off.
- To prevent the engine from starting, remove the Automatic Shut Down (ASD) relay. The ASD relay is located in the Power Distribution Center (PDC), in the engine compartment. See the fuse and relay layout label affixed to the underside of the PDC cover for ASD relay identification and location.

(1) Connect the positive lead of the voltmeter to the battery negative terminal post. Connect the negative lead of the voltmeter to the battery negative cable terminal clamp (Fig. 22). Rotate and hold the ignition switch in the Start position. Observe the voltmeter. If voltage is detected, correct the poor connection between the battery negative cable terminal clamp and the battery negative terminal post.

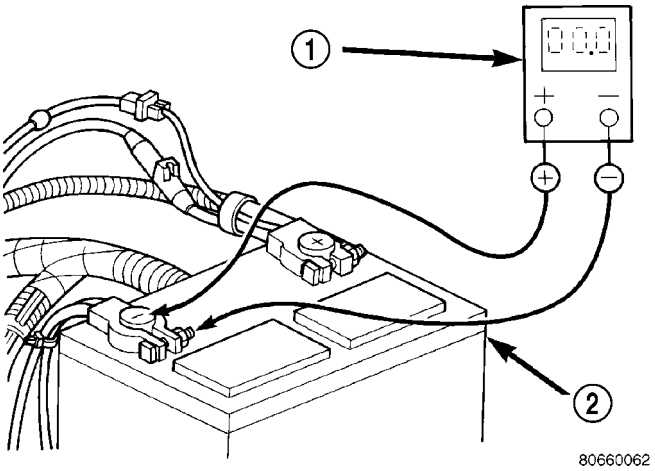

Fig. 22 Testing Battery Negative Connection Resistance

1 - VOLTMETER
2 - BATTERY

(2) Connect the positive lead of the voltmeter to the battery positive terminal post. Connect the negative lead of the voltmeter to the battery positive cable terminal clamp (Fig. 23). Rotate and hold the ignition switch in the Start position. Observe the voltmeter. If voltage is detected, correct the poor connection between the battery positive cable terminal clamp and the battery positive terminal post.

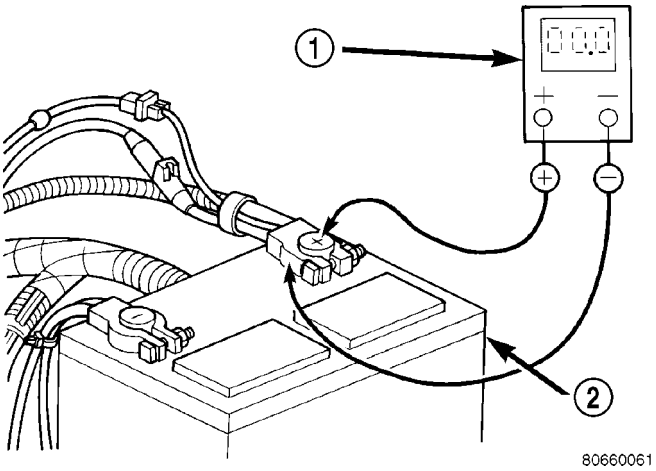

Fig. 23 Testing Battery Positive Connection Resistance

1 - VOLTMETER
2 - BATTERY

(3) Connect the voltmeter to measure between the battery positive cable terminal clamp and the starter solenoid B(+) terminal stud (Fig. 24). Rotate and hold the ignition switch in the Start position. Observe the voltmeter. If the reading is above 0.2 volt, clean and tighten the battery positive cable eyelet terminal connection at the starter solenoid B(+) terminal stud. Repeat the test. If the reading is still above 0.2 volt, replace the faulty battery positive cable.

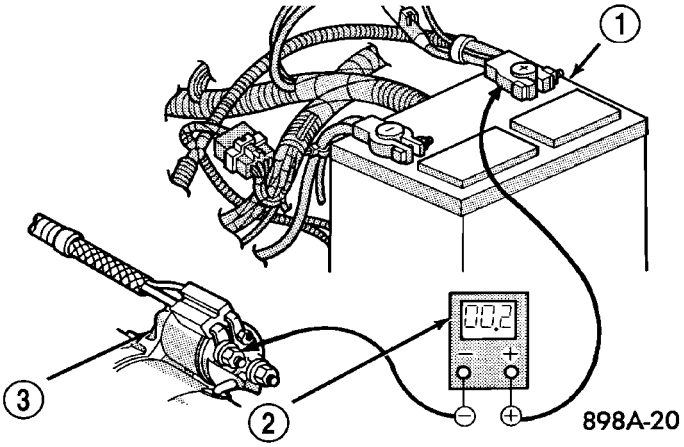

Fig. 24 Testing Battery Positive Cable Resistance

1 - BATTERY
2 - VOLTMETER
3 - STARTER MOTOR

BATTERY CABLES (Continued)

(4) Connect the voltmeter to measure between the battery negative cable terminal clamp and a good clean ground on the engine block (Fig. 25). Rotate and hold the ignition switch in the Start position. Observe the voltmeter. If the reading is above 0.2 volt, clean and tighten the battery negative cable eyelet terminal connection to the engine block. Repeat the test. If the reading is still above 0.2 volt, replace the faulty battery negative cable.

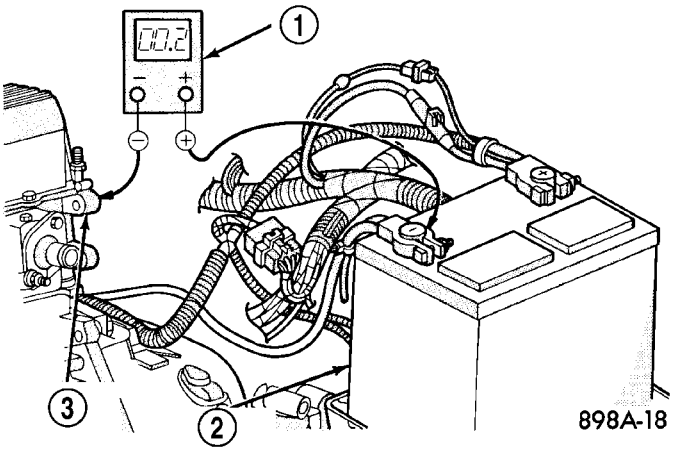

Fig. 25 Testing Ground Circuit Resistance

1 - VOLTMETER
2 - BATTERY
3 - ENGINE GROUND

REMOVAL

(1) Turn the ignition switch to the Off position. Be certain that all electrical accessories are turned off.

(2) Disconnect and isolate the remote battery negative cable terminal.

(3) Remove the battery from the vehicle. Refer to the procedure in this group.

(4) One at a time, trace the battery cable retaining pushpins, fasteners and routing clips until the cables are free from the vehicle.

(5) Remove the battery cables from the engine compartment.

INSTALLATION

(1) Position the battery cables in the engine compartment.

(2) One at a time, install the battery cable retaining pushpins, fasteners and routing clips until the cables are installed exactly where they were in the vehicle.

(3) Install the battery in the vehicle. Refer to the procedure in this group.

(4) Connect the remote battery negative cable terminal.

BATTERY TRAY

DESCRIPTION

The battery is placed and secured in a plastic battery tray. On gasoline engine equipped vehicles, the battery tray is located in the left front side of the vehicle, next to the left strut tower (Fig. 26). On diesel engine equipped vehicles, the battery tray is located in the passenger compartment, under the passenger front seat. Refer to Battery Hold down for more information on hold down hardware.

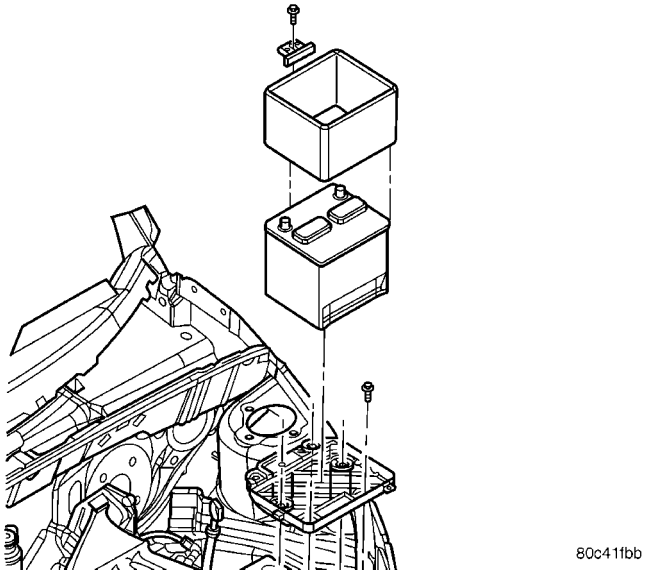

Fig. 26 Battery Remove/Install - Gasoline Engine Only

OPERATION

The battery tray provides a secure mounting location and supports the battery. On some vehicles, the battery tray also provides the anchor point/s for the battery holddown hardware. The battery tray and the battery holddown hardware combine to secure and stabilize the battery, which prevents battery movement during vehicle operation. Unrestrained battery movement during vehicle operation could result in damage to the vehicle, the battery, or both.

REMOVAL

REMOVAL - GASOLINE ENGINE

(1) Open the hood.

(2) Remove the battery (Refer to 8 - ELECTRICAL/BATTERY SYSTEM/BATTERY - REMOVAL).

(3) Remove the bolts retaining the battery tray.

(4) Lift the battery tray out of the engine compartment and remove from the vehicle.

BATTERY TRAY (Continued)

REMOVAL - DIESEL ENGINE

(1) Remove the battery (Refer to 8 - ELECTRICAL/BATTERY SYSTEM/BATTERY - REMOVAL).
(2) Remove the passengers front seat (Refer to 23 - BODY/SEATS/SEAT - REMOVAL).
(3) Remove the battery tray retaining bolt.
(4) Remove the battery tray from the vehicle.

INSTALLATION

INSTALLATION - GASOLINE ENGINE

(1) Place battery tray into place in the engine compartment.
(2) Install the bolts retaining the battery tray.
(3) Install the battery (Refer to 8 - ELECTRICAL/BATTERY SYSTEM/BATTERY - INSTALLATION).
(4) Close hood.

INSTALLATION - DIESEL ENGINE

(1) Place battery tray into place in the passenger compartment.
(2) Install the battery tray retaining bolt.
(3) Install the front passenger seat (Refer to 23 - BODY/SEATS/SEAT - INSTALLATION).
(4) Install the battery (Refer to 8 - ELECTRICAL/BATTERY SYSTEM/BATTERY - INSTALLATION).
(5) Install and connect the vent tube assembly.

THERMAL GUARD

DESCRIPTION

On gasoline engine equipped vehicles, a flexible thermal guard wraps around the battery case to enclose the sides of the battery (Fig. 27). The thermal guard consists of a plastic cloth outer skin with a polyester based insulator fiber.

OPERATION

The thermal guard protects the battery from engine compartment temperature extremes. The temperature of the battery can affect battery performance. The air trapped in the thermal guard creates a dead air space, which helps to insulate the sides of the battery case from the air temperature found in the surrounding engine compartment.

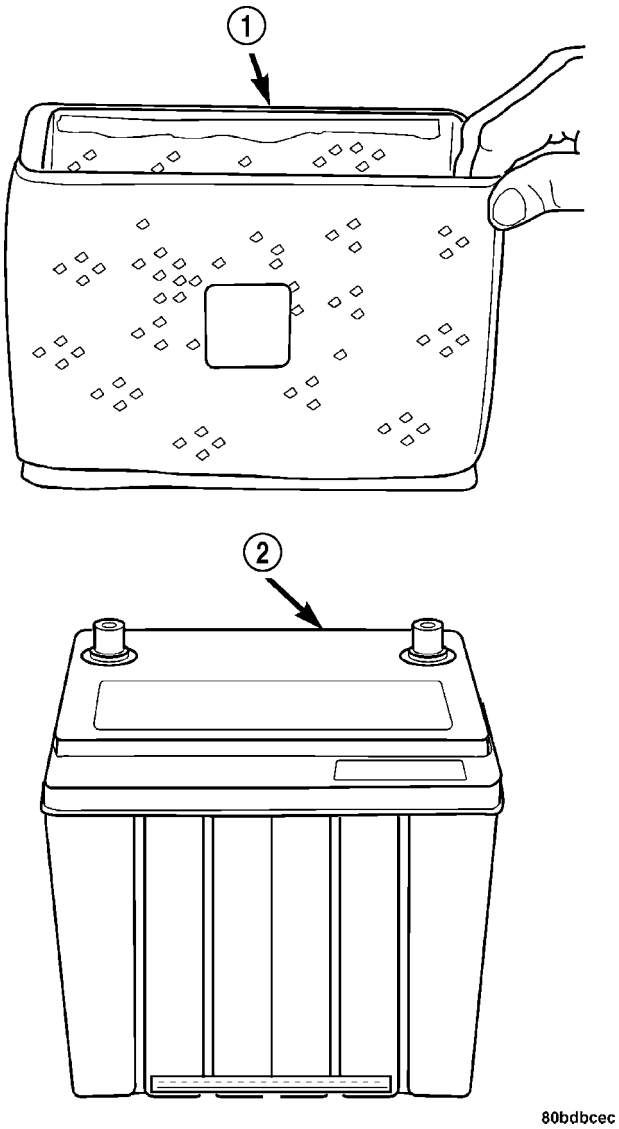

Fig. 27 Battery Thermal Guard

1 - THERMAL GUARD
2 - BATTERY

REMOVAL

WARNING:
TO PROTECT THE HANDS FROM BATTERY ACID, A SUITABLE PAIR OF HEAVY DUTY RUBBER GLOVES, NOT THE HOUSEHOLD TYPE, SHOULD BE WORN WHEN REMOVING OR SERVICING A BATTERY. SAFETY GLASSES ALSO SHOULD BE WORN.

THERMAL GUARD (Continued)

(1) Make sure ignition switch is in OFF position and all accessories are OFF.
(2) Open hood.
(3) Remove air cleaner housing (Refer to 9 - ENGINE/AIR INTAKE SYSTEM/AIR CLEANER HOUSING - REMOVAL).
(4) Disconnect and isolate the battery negative cable.
(5) Disconnect the battery positive cable.
(6) Loosen bolt and retainer that holds the battery down to the tray.
(7) Lift battery out of battery tray and remove from vehicle.
(8) Carefully lift the thermal guard off over the battery taking care not to tear it.
(9) Remove the thermal guard from battery.

INSTALLATION

When replacing battery, the thermal guard MUST be transferred to the new battery.
(1) Slip the battery thermal guard over the battery being careful not to tear it.
(2) Install battery in vehicle.
(3) Install battery hold down clamp, making sure that it is properly positioned on battery.
(4) Connect battery cable clamps to battery posts. Install battery positive cable first.
(5) Tighten clamp nuts securely.
(6) Install the air cleaner housing (Refer to 9 - ENGINE/AIR INTAKE SYSTEM/AIR CLEANER HOUSING - INSTALLATION).

BATTERY TRAY SUPPORT BRACKET

REMOVAL

(1) Disconnect and isolate the negative battery cable.
(2) Remove the air cleaner housing.
(3) Remove the battery (Refer to 8 - ELECTRICAL/BATTERY SYSTEM/BATTERY - REMOVAL).
(4) Remove the battery tray and battery temperature sensor.
(5) Raise the vehicle on a hoist.
(6) Working under the vehicle, remove two of the battery tray support bracket retaining bolts.
(7) Lower the vehicle on the hoist.
(8) Remove the remaining two battery tray support bracket retaining bolts and remove the bracket from the vehicle.

INSTALLATION

(1) Position the battery tray support bracket and install the two battery tray support bracket retaining bolts.
(2) Raise the vehicle on the hoist.
(3) Working under the vehicle, install the two battery tray support bracket retaining bolts.
(4) Lower the vehicle on a hoist.
(5) Install the battery tray and battery temperature sensor (if equipped).
(6) Install the battery (Refer to 8 - ELECTRICAL/BATTERY SYSTEM/BATTERY - INSTALLATION).
(7) Install the air cleaner housing.
(8) Connect the negative battery cable.

CHARGING

DESCRIPTION - CHARGING SYSTEM

The charging system consists of:

- Generator
- Decoupler Pulley (If equipped)
- Electronic Voltage Regulator (EVR) circuitry within the Powertrain Control Module (PCM)
- Ignition switch (refer to the Ignition System section for information)
- Battery (refer to the Battery section for information)
- Inlet Air Temperature (calculated battery temperature 1.6L)
- Battery Temperature Sensor (2.0L, 2.4L, and 2.4L turbo)
- Voltmeter (refer to the Instrument Cluster section for information if equipped)
- Wiring harness and connections (refer to the Wiring section for information)
- Accessory drive belt (refer to the Cooling section for more information)

OPERATION - CHARGING SYSTEM

The charging system is turned on and off with the ignition switch. The system is on when the engine is running and the ASD relay is energized. The ASD relay is energized when the PCM grounds the ASD control circuit. This voltage is connected through the PCM or IPM (intelligent power module) and supplied to one of the generator field terminals (Gen. Source +) at the back of the generator.

The generator is driven by the engine through a serpentine belt and pulley or decoupler pulley arrangement.

The amount of DC current produced by the generator is controlled by the EVR (field control) circuitry contained within the PCM. This circuitry is connected in series with the second rotor field terminal and ground.

Battery temperature is detected using a stand alone sensor for vehicles having 2.0, 2.4, and 2.4L Turbo engines. For 1.6L engines vehicles battery temperature is predicted using the values of 4 existing sensors inputs. These inputs are Inlet Air Sensor, Coolant Sensor, Vehicle Speed Sensor, and Fan State (on/off). The charging lamp will come on if either the inlet air temperature, coolant temperature, or vehicle speed sensor fail. If one of these sensors fail the charging system will default to 13.5 Volts. This temperature data, along with data from monitored line voltage (ASD voltage sense circuit), is used by the PCM to vary the battery charging rate. This is done by cycling the ground path to control the strength of the rotor magnetic field. The PCM then compensates and regulates generator current output accordingly to maintain system voltage at the targeted system voltage based on battery temperature.

All vehicles are equipped with On-Board Diagnostics (OBD). All OBD-sensed systems, including EVR (field control) circuitry, are monitored by the PCM. Each monitored circuit is assigned a Diagnostic Trouble Code (DTC). The PCM will store a DTC in electronic memory for certain failures it detects. Refer to On-Board Diagnostics in the Electronic Control Modules(Refer to 8 - ELECTRICAL/ELECTRONIC CON-

CHARGING (Continued)

TROL MODULES/POWERTRAIN CONTROL MODULE - DESCRIPTION) section for more DTC information.

The Check Gauges Lamp (if equipped) monitors: **charging system voltage,** engine coolant temperature and engine oil pressure. If an extreme condition is indicated, the lamp will be illuminated. This is done as reminder to check the three gauges. The signal to activate the lamp is sent via the PCI bus circuits. The lamp is located on the instrument panel. Refer to the Instrument Cluster section for additional information.

DIAGNOSIS AND TESTING - ON-BOARD DIAGNOSTIC SYSTEM

The Powertrain Control Module (PCM) monitors critical input and output circuits of the charging system, making sure they are operational. A Diagnostic Trouble Code (DTC) is assigned to each input and output circuit monitored by the OBD system. Some circuits are checked continuously and some are checked only under certain conditions.

If the OBD system senses that a monitored circuit is bad, it will put a DTC into electronic memory. The DTC will stay in electronic memory as long as the circuit continues to be bad. The PCM is programmed to clear the memory after 40 good trip if the problem does not occur again.

DIAGNOSTIC TROUBLE CODES

A DTC description can be read using the DRBIII® scan tool. Refer to the appropriate Powertrain Diagnostic Procedures manual for information.

A DTC does not identify which component in a circuit is bad. Thus, a DTC should be treated as a symptom, not as the cause for the problem. In some cases, because of the design of the diagnostic test procedure, a DTC can be the reason for another DTC to be set. Therefore, it is important that the test procedures be followed in sequence, to understand what caused a DTC to be set.

ERASING DIAGNOSTIC TROUBLE CODES

The DRBIII® Scan Tool must be used to erase a DTC.

The following procedures may be used to diagnose the charging system if:

- the check gauges lamp or battery lamp is illuminated with the engine running
- the voltmeter (if equipped) does not register properly
- an undercharged or overcharged battery condition occurs.

Remember that an undercharged battery is often caused by:

- accessories being left on with the engine not running
- a faulty or improperly adjusted switch that allows a lamp to stay on. Refer to Ignition-Off Draw Test (Refer to 8 - ELECTRICAL/BATTERY SYSTEM/ BATTERY - STANDARD PROCEDURE)
- loose generator belt.

INSPECTION

The Powertrain Control Module (PCM) monitors critical input and output circuits of the charging system, making sure they are operational. A Diagnostic Trouble Code (DTC) is assigned to each input and output circuit monitored by the On-Board Diagnostic (OBD) system. Some charging system circuits are checked continuously, and some are checked only under certain conditions.

Refer to Diagnostic Trouble Codes in; Powertrain Control Module; Electronic Control Modules for more DTC information. This will include a complete list of DTC's including DTC's for the charging system.

To perform a complete test of the charging system, refer to the appropriate Powertrain Diagnostic Procedures service manual and the DRBIII® scan tool. Perform the following inspections before attaching the scan tool.

(1) Inspect the battery condition. Refer to the Battery section (Refer to 8 - ELECTRICAL/BATTERY SYSTEM - DIAGNOSIS AND TESTING) for procedures.

(2) Inspect condition of battery cable terminals, battery posts, connections at engine block, starter solenoid and relay. They should be clean and tight. Repair as required.

(3) Inspect all fuses in both the fuseblock and Power Distribution Center (PDC) or IPM (if equipped) for tightness in receptacles. They should be properly installed and tight. Repair or replace as required.

(4) Inspect generator mounting bolts for tightness. Replace or tighten bolts if required. Refer to the Generator Removal/Installation section of this group for torque specifications (Refer to 8 - ELECTRICAL/ CHARGING - SPECIFICATIONS).

(5) Inspect generator drive belt condition and tension. Tighten or replace belt as required. Refer to Belt Tension Specifications(Refer to 7 - COOLING/ ACCESSORY DRIVE - SPECIFICATIONS).

(6) Inspect decoupler pulley (if equipped). Ensure decoupler pulley is driving the alternator rotor.

(7) Inspect automatic belt tensioner (if equipped). Refer to the Cooling System for more information.

(8) Inspect generator electrical connections at generator field, battery output, and ground terminal (if equipped). Also check generator ground wire connection at engine (if equipped). They should all be clean and tight. Repair as required.

BATTERY TEMPERATURE SENSOR

OPERATION

The battery temperature sensor is used to determine the battery temperature and control battery charging rate. This temperature data, along with data from monitored line voltage, is used by the PCM to vary the battery charging rate. System voltage will be higher at colder temperatures and is gradually reduced at warmer temperatures.

The sensor is located on the bottom of the battery tray, and makes contacts with the bottom of the battery.

REMOVAL - 2.0, 2.4, and 2.4L TURBO

(1) Disconnect the negative battery cable.
(2) Remove the air cleaner box (Fig. 1).
(3) Remove battery (Fig. 2).
(4) Lift battery tray bottom up.
(5) Disconnect the electrical connector from sensor (Fig. 3).
(6) Remove sensor from battery tray by unlocking tabs from battery tray (Fig. 4) and remove the sensor (Fig. 5).

GENERATOR

DESCRIPTION

The generator is belt-driven by the engine. It is serviced only as a complete assembly. If the generator fails for any reason, the entire assembly must be replaced. The generator produces DC voltage.

OPERATION

As the energized rotor begins to rotate within the generator, the spinning magnetic field induces a current into the windings of the stator coil.

The Y type stator winding connections deliver the induced AC current to 3 positive and 3 negative diodes for rectification. From the diodes, rectified DC current is delivered to the vehicles electrical system through the generator, battery, and ground terminals.

Noise emitting from the generator may be caused by:

- Worn, loose or defective bearings
- Loose or defective drive pulley
- Incorrect, worn, damaged or misadjusted drive belt
- Loose mounting bolts
- Misaligned drive pulley
- Defective stator or diode
- Damaged internal fins

REMOVAL

REMOVAL - 2.0/2.4L

(1) Remove the air cleaner lid, disconnect the inlet air sensor and makeup air hose.

(2) Disconnect the negative battery cable.

(3) Loosen the upper generator T-bolt lock nut (Fig. 7).

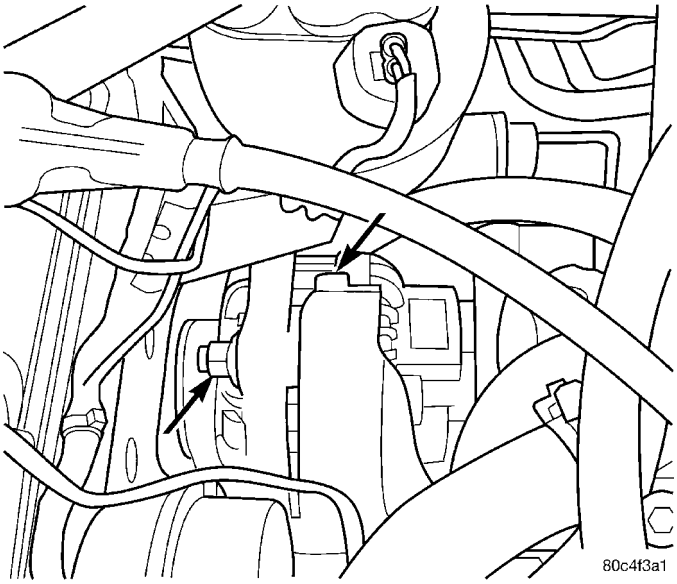

Fig. 7 Generator T-Bolt Locknut and Adjustment Bolt

(4) Raise vehicle on hoist.

(5) Remove the right front wheel.

(6) Remove the accessory drive splash shield (Fig. 8).

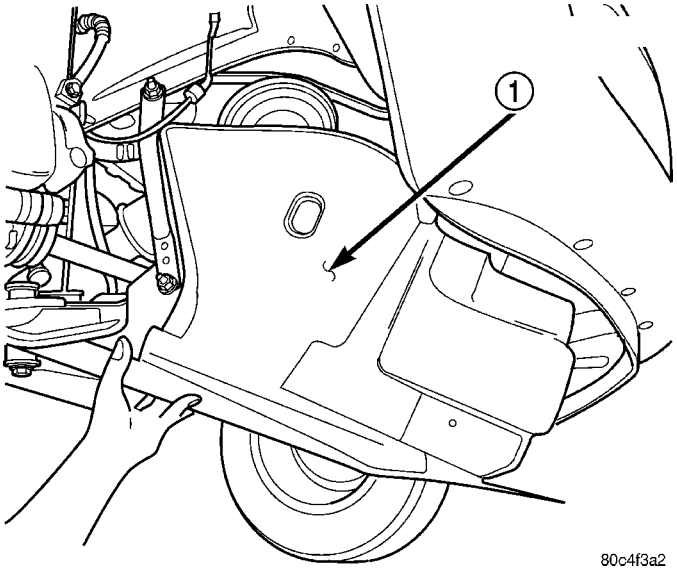

Fig. 8 Accessory Drive Splash Shield

1 - ACCESSORY DRIVE BELT SPLASH SHIELD

(7) Remove the pencil strut (Fig. 9).

(8) Loosen the lower pivot bolt (Fig. 10).

(9) Loosen the accessory drive belt t-bolt.

(10) Unplug field circuit from generator (Fig. 11).

(11) Remove the B+ terminal nut and wire.

(12) Remove the generator belt, refer to the Cooling section for more information.

REMOVAL - 2.2 DIESEL

(1) Disconnect the negative battery cable.

(2) Remove the front grill, refer to the Body section for more information.

(3) Remove the hood seal, refer to the Body section for more information.

(4) Remove the upper radiator crossmember.

(5) Remove ambient temperature sensor.

(6) Raise vehicle and support.

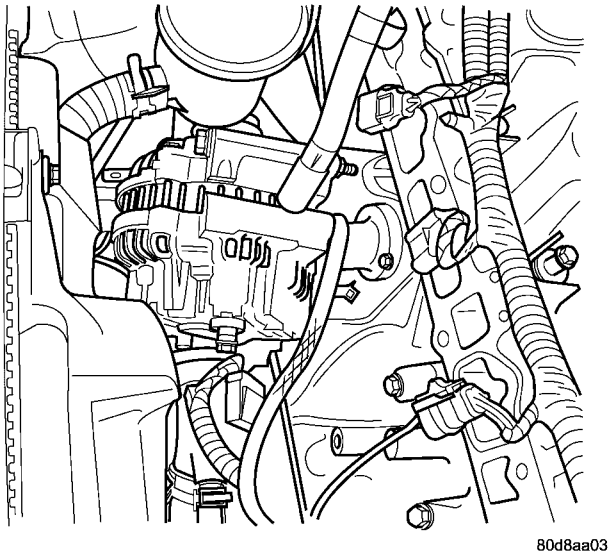

Fig. 27 GENERATOR REMOVAL

(7) Drain radiator, refer to the Cooling section for more information.

(8) Disconnect the electrical connector for the radiator fan.

(9) Remove A/C refrigerant. Refer to the Air Conditioning section for more information.

(10) Remove the underbody plate (skid plate), refer to the Body section for more information.

(11) Remove the lower radiator hose and the 2 inner cooler hoses.

(12) Remove the right front tire.

(13) Remove the splash shield.

(14) Remove the accessory drive belt, refer to the Cooling section for more information.

(15) Lower vehicle.

(16) Disconnect the A/C lines from the condenser and plug and cap.

(17) Remove the upper radiator hose.

(18) Remove the radiator, condenser, and inner cooler assembly

(19) Loosen the 2 lower mounting bolts for the generator and remove the accessory drive idler pulley and bracket (Fig. 28).

(20) Disconnect the wiring connectors from the back of the generator (Fig. 29).

NOTE: The orientation of the generator, it will fit onto the bracket backwards. If this occurs damage to the generator will happen.

(21) Remove the A/C line from the compressor.

(22) Remove the 2 upper bolts and the 2 lower bolts and remove generator as assembly.

GENERATOR (Continued)

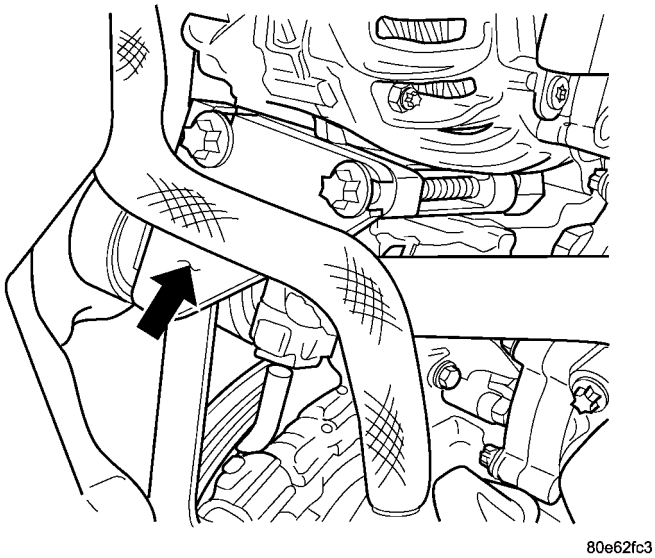

Fig. 28 IDLER PULLEY BRACKET

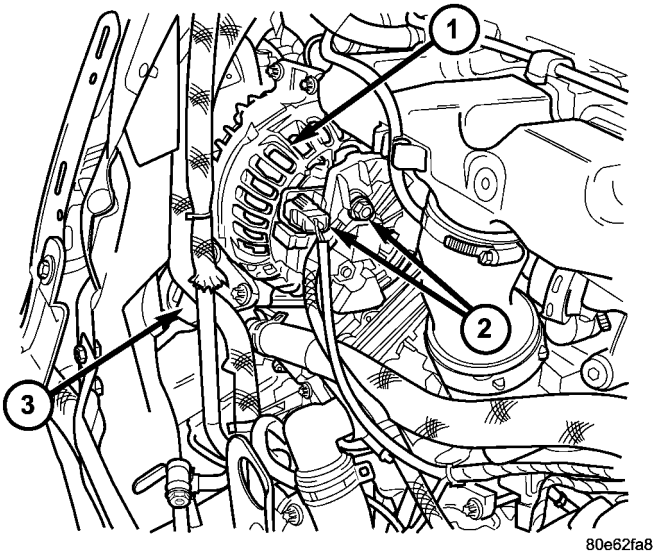

Fig. 29 GENERATOR LOCATION

1 - Generator
2 - Eletrical Connertors
3 - Idler Pulley and Bracket

INSTALLATION

INSTALLATION - 2.0/2.4L

(1) Install generator (Fig. 12) and loose assemble the bolt and nut (Fig. 10).

(2) Install and tension the generator belt, refer to the Cooling section for more information.

(3) Tighten the lower pivot bolt to 54 N·m (40 ft. lbs.)

(4) Install axle shaft, refer to the Axle section

(5) Install lower control arm to steering knuckle, refer to the Supension section.

(6) Install the lower ball joint nut and tighten, refer to the Supension section.

(7) Install the axle retaining nut and tighten, refer to the Axle section.

(8) Install the pencil strut (Fig. 9), refer to the body section.

(9) Install the B+ terminal nut and wire and tighten (Fig. 11) to 11.3 N·m (100 ins. lbs.).

(10) Plug in the field circuit to the generator

(11) Install the accessory drive splash shield (Fig. 8).

(12) Install the right front wheel, refer to the Wheels and Tire section.

(13) Lower vehicle.

(14) Tighten the T-bolt locknut (Fig. 7) and tighten to 54 N·m (40 ft. lbs.)

(15) Connect the negative battery cable.

(16) Install the air cleaner lid and connect the inlet air temperature sensor and makeup hose.

(17) Check the transmission fluid.

INSTALLATION - 2.4L TURBO

(1) Install generator through the axle shaft hole in wheel well (Fig. 22).

(2) Put generator on upper t-bolt and loosen install the nut (Fig. 15).

(3) Install the lower mounting bracket (Fig. 21) for the generator to the block and tighten bolts to 54 N·m (40 ft. lbs.).

(4) Loose install the lower pivot bolt for the generator (Fig. 19).

(5) Install the B+ terminal nut and wire (Fig. 17) and tighten nut to 11.3 N·m (100 in. lbs.).

(6) Plug in the field circuit to the generator.

(7) Install the axle shaft assembly (Fig. 20).

(8) Install the 2 bolts for the axle shaft bearing support and tighten bolts to 54.2 N·m (40 ft. lbs).

(9) Install the axle shaft into the steering knuckle (Fig. 20).

(10) Install the lower control arm to the steering knuckle and install the bolt and tighten bolts to 94.9 N·m (70 ft. lbs.).

(11) Install the axle retaining nut and tighten nut to 244 N·m (180 ft. lbs.).

(12) Install and tension the generator belt, refer to the Cooling section for more information.

(13) Tighten the accessory drive belt t-bolt and tighten nut to 54 N·m (40 ft. lbs.) (Fig. 15).

(14) Tighten the lower generator pivot bolt and tighten bolts to 54 N·m (40 ft. lbs.).

(15) Install the pencil strut (Fig. 18).

(16) Install the generator heat shield.

(17) Install the lower heat shield bolt and tighten bolt to 54.2 N·m (40 ft. lbs.).

(18) Install the accessory drive splash shield (Fig. 16).

GENERATOR (Continued)

(19) Install the right front wheel.
(20) Lower vehicle.
(21) Tighten nut to the upper adjustment bracket (Fig. 15) and tighten to 25 N·m (18 ft. lbs.).
(22) Install the 2 bolts to the heat shield on the generator (Fig. 14) and tighten bolts to 4.5 N·m (40 in. lbs.).
(23) Connect the negative battery cable.

INSTALLATION - 1.6L

(1) Install the 2 lower and 1 upper mounting bolts into the generator (Fig. 30).

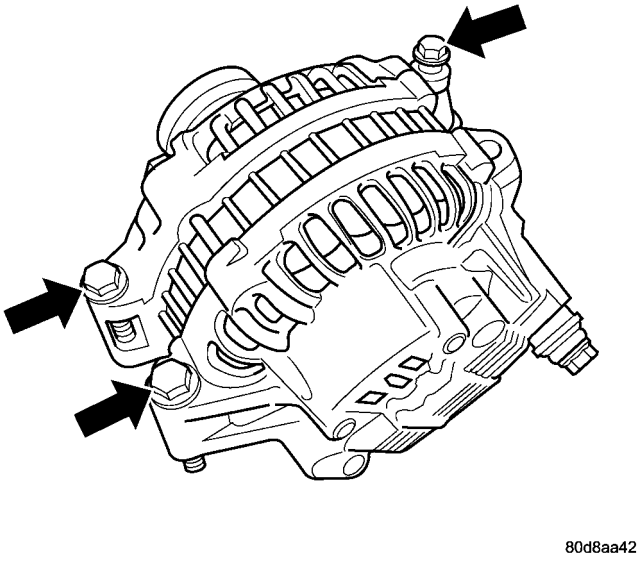

Fig. 30 GENERATOR BOLTS

(2) Install the generator to the vehicle (Fig. 27).
(3) Hand start the bolts.
(4) Install the upper inboard mounting bolts and hand start the bolt.
(5) Raise vehicle and support.
(6) Tighten the outboard generator mounting bolt. Torque to 28 N·m (250 in. lbs.).
(7) Install the accessory drive belt, refer to the cooling section for more information.
(8) Install the right splash shield.
(9) Lower vehicle.
(10) Tighten the lower inboard generator mounting bolt. Torque to 28 N·m (250 in. lbs.).
(11) Tighten the upper 2 mounting bolts. Torque to 28 N·m (250 in. lbs.).
(12) Install the power steering reservoir to the support bracket (Fig. 24).
(13) Connect the electrical connectors to the generator (Fig. 23).
(14) Install the lower intake manifold, refer to the engine section for more information.
(15) Install the fuel rail.
(16) Install the 2 bolts to the fuel rail at the lower manifold.
(17) Install the fuel line to the fuel rail.
(18) Install the wiring harness to the fuel rail brackets.
(19) Connect the electrical connectors to the fuel injectors.
(20) Connect the negative battery cable.
(21) Install air cleaner assembly cover.

INSTALLATION - 2.2 DIESEL

NOTE: The orientation of the generator (Fig. 31), it will fit onto the bracket backwards. If this occurs damage to the generator will happen.

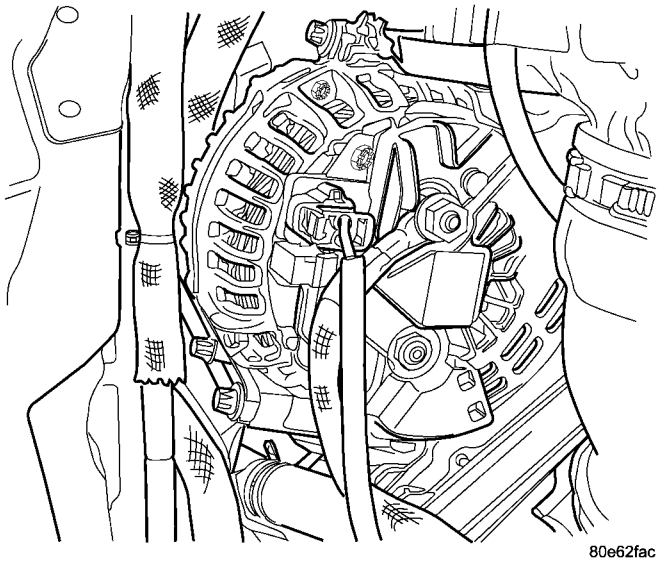

Fig. 31 GENERATOR ORIENTATION

(1) Install the 2 upper bolts and the 2 lower bolts into the generator.
(2) Install generator as assembly (Fig. 31) **MAKE SURE OF ORIENTATION OF GENERATOR**.
(3) Install the accessory drive idler pulley and bracket to the 2 lower mounting bolts for the generator (Fig. 28).
(4) Tighten generator mounting bolts to 28 N·m (38 ft. lbs.)
(5) Connect the wiring connectors to the back of the generator (Fig. 29).
(6) Connect the battery cable to the generator.
(7) Install the A/C line to the compressor.
(8) Install the radiator, condenser, and inner cooler assembly
(9) Connect the electrical connector to the radiator fan.
(10) Install the upper radiator hose.
(11) Connect the A/C line to the condenser.
(12) Raise vehicle and support.
(13) Install the accessory drive belt, refer to the Cooling section for more information.
(14) Install the splash shield.

GENERATOR (Continued)

(15) Install the right front tire.

(16) Install the lower radiator hose and the 2 inner cooler hoses.

(17) Install the underbody plate (skid plate), refer to the Body section for more information.

(18) Lower vehicle.

(19) Install ambient temperature sensor.

(20) Install the upper radiator crossmember.

(21) Install the hood seal, refer to the Body section for more information.

(22) Install the front grill, refer to the Body section for more information.

(23) Connect the negative battery cable.

(24) Fill radiator, refer to the Cooling section for more information.

(25) Install A/C refrigerant. Refer to the Air Conditioning section for more information.

VOLTAGE REGULATOR

DESCRIPTION

The Electronic Voltage Regulator (EVR) is not a separate component. It is actually a voltage regulating circuit located within the Powertrain Control Module (PCM). The EVR is not serviced separately. If replacement is necessary, the PCM must be replaced.

OPERATION

The amount of DC current produced by the generator is controlled by EVR circuitry contained within the PCM. This circuitry is connected in series with the generators second rotor field terminal and its ground.

Voltage is regulated within the PCM on the NGC vehicles, to control the strength of the rotor magnetic field. The EVR circuitry monitors system line voltage at the PDC and calculated battery temperature or inlet air temperature sensor (refer to Inlet Air Temperature Sensor, if equipped, for more information). It then determines a target charging voltage. If sensed battery voltage is lower than the target voltage, the PCM feeds the field winding until sensed battery voltage is at the target voltage. A circuit in the PCM cycles the feed side of the generator field at 250 times per second (250Hz), but has the capability to feed the field control wire 100% of the time (full field) to achieve the target voltage. If the charging rate cannot be monitored (limp-in), a duty cycle of 20% is used by the PCM in order to have some generator output. Also refer to Charging System Operation for additional information.

STARTING

DESCRIPTION

The starting system consists of:

- Starter relay
- Starter motor (including an integral starter solenoid)

Other components to be considered as part of starting system are:

- Battery
- Battery cables
- Ignition switch and key lock cylinder
- Clutch pedal position switch (manual transmission)
- Park/neutral position switch (automatic transmission)
- Wire harnesses and connections.

The Battery, Starting, and Charging systems operate in conjunction with one another, and must be tested as a complete system. For correct operation of starting/charging systems, all components used in these 3 systems must perform within specifications. When attempting to diagnose any of these systems, it is important that you keep their interdependency in mind.

The diagnostic procedures used in each of these groups include the most basic conventional diagnostic methods, to the more sophisticated On-Board Diagnostics (OBD) built into the Powertrain Control Module (PCM). Use of an induction-type milliampere ammeter, volt/ohmmeter, battery charger, carbon pile rheostat (load tester), and 12-volt test lamp may be required.

OPERATION

These components form two separate circuits. A high amperage circuit that feeds the starter motor up to 300+ amps, and a control circuit that operates on less than 20 amps.

The PCM controls a double start over-ride safety that does not allow the starter to be engaged if the engine is already running.

DIAGNOSIS AND TESTING

DIAGNOSIS AND TESTING - STARTING SYSTEM TEST

For circuit descriptions and diagrams, refer to the Wiring Diagrams.

WARNING: ON VEHICLES EQUIPPED WITH AIRBAGS, REFER TO THE PASSIVE RESTRAINT SYSTEMS BEFORE ATTEMPTING STEERING WHEEL, STEERING COLUMN, OR INSTRUMENT PANEL COMPONENT DIAGNOSIS OR SERVICE. FAILURE TO TAKE THE PROPER PRECAUTIONS COULD RESULT IN ACCIDENTAL AIRBAG DEPLOYMENT AND POSSIBLE PERSONAL INJURY.

INSPECTION

Before removing any unit from the starting system for repair or diagnosis, perform the following inspections:

- **Battery** - Visually inspect the battery for indications of physical damage and loose or corroded cable connections. Determine the state-of-charge and

STARTING (Continued)

cranking capacity of the battery. Charge or replace the battery, if required. Refer to the Battery section for more information.

- **Ignition Switch** - Visually inspect the ignition switch for indications of physical damage and loose or corroded wire harness connections.
- **Transmission Range Sensor or Park/Neutral Switch** - Visually inspect the transmission range sensor for indications of physical damage and loose or corroded wire harness connections.
- **Starter Relay** - Visually inspect the starter relay for indications of physical damage and loose or corroded wire harness connections.
- **Starter Motor** - Visually inspect the starter motor for indications of physical damage and loose or corroded wire harness connections.
- **Starter Solenoid** - Visually inspect the starter solenoid for indications of physical damage and loose or corroded wire harness connections.
- **Wiring** - Visually inspect the wire harness for damage. Repair or replace any faulty wiring, as required. Check for loose or corroded wire harness connections at main engine ground and remote jump post.
- **Power Distribution Center (PDC)** - Visually inspect the B+ connections at the PDC for physical damage and loose or corroded harness connections.

STARTING SYSTEM DIAGNOSIS

CONDITION	POSSIBLE CAUSE	CORRECTION
STARTER FAILS TO ENGAGE.	1. BATTERY DISCHARGED OR FAULTY.	1. REFER TO THE BATTERY SECTION FOR MORE INFORMATION. CHARGE OR REPLACE BATTERY, IF REQUIRED.
	2. STARTING CIRCUIT WIRING FAULTY.	2. REFER TO FEED CIRCUIT RESISTANCE TEST AND FEED CIRCUIT TEST IN THIS SECTION.
	3. STARTER RELAY FAULTY.	3. REFER TO RELAY TEST, IN THIS SECTION. REPLACE RELAY, IF NECESSARY.
	4. IGNITION SWITCH FAULTY.	4. REFER TO IGNITION SWITCH TEST, IN THE STEERING SECTION OR 8 WIRING DIAGRAMS. REPLACE SWITCH, IF NECESSARY.
	5. PARK/NEUTRAL POSITION SWITCH (AUTO TRANS) FAULTY OR MIS-ADJUSTED.	5. REFER PARK/NEUTRAL POSITION SWITCH TEST, IN THE TRANSAXLE. SECTION FOR MORE INFORMATION. REPLACE SWITCH, IF NECESSARY.
	6. CLUTCH INTERLOCK SWITCH (MAN TRANS) FAULTY.	6. REFER TO CLUTCH PEDAL POSITION SWITCH TEST, IN THE CLUTCH. SECTION. REPLACE SWITCH, IF NECESSARY.
	7. STARTER SOLENOID FAULTY.	7. REFER TO SOLENOID TEST, IN THIS SECTION. REPLACE STARTER ASSEMBLY, IF NECESSARY.
	8. STARTER ASSEMBLY FAULTY.	8. IF ALL OTHER STARTING SYSTEM COMPONENTS AND CIRCUITS CHECK OK, REPLACE STARTER ASSEMBLY.
	9. FAULTY TEETH ON RING GEAR.	9. ROTATE FLYWHEEL 360°, AND INSPECT TEETH AND RING GEAR REPLACED IF DAMAGED.
	10. PCM DOUBLE START OVERRIDE OUTPUT FAILURE.	10. REFER TO PCM DIAGNOSTIC. CHECK FOR CONTINUITY BETWEEN PCM AND TERMINAL 85. REPAIR OPEN CIRCUIT AS REQUIRED. IF OK, PCM MAY BE DEFECTIVE.
STARTER ENGAGES, FAILS TO TURN ENGINE.	1. BATTERY DISCHARGED OR FAULTY.	1. REFER TO THE BATTERY SECTION FOR MORE INFORMATION. CHARGE OR REPLACE BATTERY AS NECESSARY.

STARTING (Continued)

CONDITION	POSSIBLE CAUSE	CORRECTION
	2. STARTING CIRCUIT WIRING FAULTY.	2. REFER TO THE FEED CIRCUIT RESISTANCE TEST AND THE FEED CIRCUIT TEST IN THIS SECTION. REPAIR AS NECESSARY.
	3. STARTER ASSEMBLY FAULTY.	3. IF ALL OTHER STARTING SYSTEM COMPONENTS AND CIRCUITS CHECK OK, REPLACE STARTER ASSEMBLY.
	4. ENGINE SEIZED.	4. REFER TO THE ENGINE SECTION, FOR DIAGNOSTIC AND SERVICE PROCEDURES.
	5. LOOSE CONNECTION AT BATTERY, PDC, STARTER, OR ENGINE GROUND.	5. INSPECT FOR LOOSE CONNECTIONS.
	6. FAULTY TEETH ON RING GEAR.	6. ROTATE FLYWHEEL 360°, AND INSPECT TEETH AND RING GEAR REPLACED IF DAMAGED.
STARTER ENGAGES, SPINS OUT BEFORE ENGINE STARTS.	1. BROKEN TEETH ON STARTER RING GEAR.	1. REMOVE STARTER. INSPECT RING GEAR AND REPLACE IF NECESSARY.
	2. STARTER ASSEMBLY FAULTY.	2. IF ALL OTHER STARTING SYSTEM COMPONENTS AND CIRCUITS CHECK OK, REPLACE STARTER ASSEMBLY.
STARTER DOES NOT DISENGAGE.	1. STARTER IMPROPERLY INSTALLED.	1. INSTALL STARTER. TIGHTEN STARTER MOUNTING HARDWARE TO CORRECT TORQUE SPECIFICATIONS.
	2. STARTER RELAY FAULTY.	2. REFER TO RELAY TEST, IN THIS SECTION. REPLACE RELAY, IF NECESSARY.
	3. IGNITION SWITCH FAULTY.	3. REFER TO IGNITION SWITCH TEST, IN THE STEERING SECTION. REPLACE SWITCH, IF NECESSARY.
	4. STARTER ASSEMBLY FAULTY.	4. IF ALL OTHER STARTING SYSTEM COMPONENTS AND CIRCUITS CHECK OK, REPLACE STARTER ASSEMBLY.
	5. FAULTY TEETH ON RING GEAR.	5. ROTATE FLYWHEEL 360°, AND INSPECT TEETH AND RING GEAR REPLACED IF DAMAGED.

DIAGNOSIS AND TESTING - CONTROL CIRCUIT TEST

The starter control circuit has:

- Starter motor with integral solenoid
- Starter relay
- Transmission range sensor, or Park/Neutral Position switch with automatic transmissions
- Ignition switch
- Battery
- All related wiring and connections
- Powertrain Control Module (PCM)

CAUTION: Before performing any starter tests, the ignition and fuel systems must be disabled.

- To disable ignition and fuel systems, disconnect the Automatic Shutdown Relay (ASD). The ASD relay is located in the Power Distribution Center (PDC). Refer to the PDC cover for the proper relay location.

STARTER SOLENOID

WARNING: CHECK TO ENSURE THAT THE TRANSMISSION IS IN THE PARK POSITION WITH THE PARKING BRAKE APPLIED. THIS MAY RESULT IN PERSONAL INJURY OR DEATH.

(1) Verify battery condition. Battery must be in good condition with a full charge before performing any starter tests. Refer to Battery Tests.

STARTING (Continued)

(2) Perform Starter Solenoid test BEFORE performing the starter relay test.

(3) Perform a visual inspection of the starter/starter solenoid for corrosion, loose connections or faulty wiring.

(4) Locate and remove the starter relay from the Power Distribution Center (PDC). Refer to the PDC label for relay identification and location.

(5) Connect a remote starter switch or a jumper wire between the remote battery positive post and terminal 87 of the starter relay connector.

(a) If engine cranks, starter/starter solenoid is good. Go to the Starter Relay Test.

(b) If engine does not crank or solenoid chatters, check wiring and connectors from starter relay to starter solenoid and from the battery positive terminal to starter post for loose or corroded connections. Particularly at starter terminals.

(c) Repeat test. If engine still fails to crank properly, trouble is within starter or starter mounted solenoid, and replace starter. Inspect the ring gear teeth.

STARTER RELAY

WARNING: CHECK TO ENSURE THAT THE TRANSMISSION IS IN THE PARK/NEUTRAL POSITION WITH THE PARKING BRAKE APPLIED. THIS MAY RESULT IN PERSONAL INJURY OR DEATH.

RELAY TEST

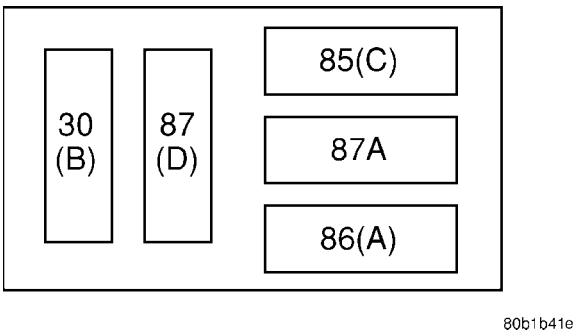
The starter relay is located in the Power Distribution Center (PDC) in the engine compartment. Refer to the PDC label for relay identification and location.

Remove the starter relay from the PDC as described in this group to perform the following tests:

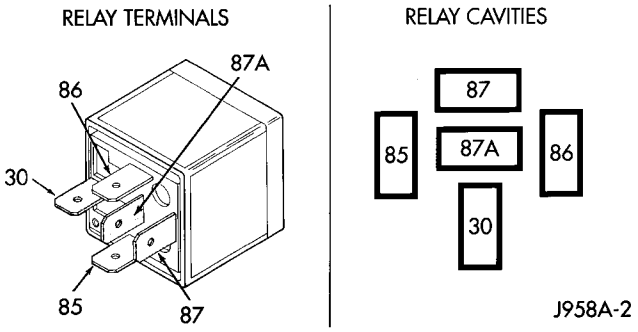
(1) A relay in the de-energized position should have continuity between terminals 87A and 30, and no continuity between terminals 87 and 30. If OK, go to Step 2. If not OK, replace the faulty relay.

(2) Resistance between terminals 85 and 86 (electromagnet) should be 75 ±5 ohms. If OK, go to Step 3. If not OK, replace the faulty relay.

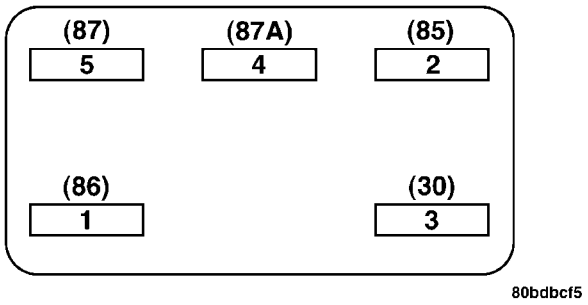
(3) Connect a battery B+ lead to terminals 85 and a ground lead to terminal 86 to energize the relay. The relay should click. Also test for continuity between terminals 30 and 87, and no continuity between terminals 87A and 30. If OK, refer to Relay Circuit Test procedure. If not OK, replace the faulty relay.



Starter Relay Pinout



Starter Relay Pinout



Starter Relay Pinout

CAV	FUNCTION
30	B (+)
85	IGNITION SWITCH OUTPUT
86	PCM-CONTROLLED GROUND
87	STARTER RELAY OUTPUT
87A	NO CONNECT

RELAY CIRCUIT TEST

(1) The relay common feed terminal cavity (30) is connected to battery voltage and should be hot at all times. If OK, go to Step 2. If not OK, repair the open circuit to the PDC fuse as required.

STARTING (Continued)

(2) The relay normally closed terminal (87A) is connected to terminal 30 in the de-energized position, but is not used for this application. Go to Step 3.

(3) The relay normally open terminal (87) is connected to the common feed terminal (30) in the energized position. This terminal supplies battery voltage to the starter solenoid field coils. There should be continuity between the cavity for relay terminal 87 and the starter solenoid terminal at all times. If OK, go to Step 4. If not OK, repair the open circuit to the starter solenoid as required.

(4) The coil battery terminal (85) is connected to the electromagnet in the relay. It is energized when the ignition switch is held in the Start position and the clutch pedal is depressed (manual trans). Check for battery voltage at the cavity for relay terminal 86 with the ignition switch in the Start position and the clutch pedal is depressed (manual trans), and no voltage when the ignition switch is released to the On position. If OK, go to Step 5. If not OK, check for an open or short circuit to the ignition switch and repair, if required. If the circuit to the ignition switch is OK, see the Ignition Switch Test procedure in this group.

(5) The coil ground terminal (86) is connected to the electromagnet in the relay. It is grounded by the PCM if the conditions are right to start the car. For automatic trans. cars the PCM must see Park Neutral switch low and near zero engine speed (rpm). For manual trans. cars the PCM only needs to see near zero engine speed (rpm) and low clutch interlock input and see near zero engine speed (rpm). To diagnose the Park Neutral switch of the trans range sensor refer to the transaxle section. Check for continuity to ground while the ignition switch is in the start position and if equipped the clutch pedal depressed. If not OK and the vehicle has an automatic trans. verify Park Neutral switch operation. If that checks OK check for continuity between PCM and the terminal 86. Repair open circuit as required. Also check the clutch interlock switch operation if equipped with a manual transmission. If OK, the PCM may be defective.

SAFETY SWITCHES

For diagnostics of the Transmission Range Sensor, refer to the Transaxle section for more information.

If equipped with Clutch Interlock/Upstop Switch, refer to Diagnosis and Testing in the Clutch section.

IGNITION SWITCH

After testing starter solenoid and relay, test ignition switch and wiring. Refer to the Ignition Section or Wiring Diagrams for more information. Check all wiring for opens or shorts, and all connectors for being loose or corroded.

BATTERY

For battery diagnosis and testing, refer to the Battery section for procedures.

ALL RELATED WIRING AND CONNECTORS

Refer to Wiring Diagrams for more information.

DIAGNOSIS AND TESTING - FEED CIRCUIT RESISTANCE TEST

Before proceeding with this operation, review Diagnostic Preparation and Starter Feed Circuit Tests. The following operation will require a voltmeter, accurate to 1/10 of a volt.

CAUTION: Ignition and Fuel systems must be disabled to prevent engine start while performing the following tests.

(1) To disable the Ignition and Fuel systems, disconnect the Automatic Shutdown Relay (ASD). The ASD relay is located in the Power Distribution Center (PDC). Refer to the PDC cover for proper relay location.

(2) Gain access to battery terminals.

(3) With all wiring harnesses and components properly connected, perform the following:

(a) Connect the negative lead of the voltmeter to the battery negative post, and positive lead to the battery negative cable clamp. Rotate and hold the ignition switch in the START position. Observe the voltmeter. If voltage is detected, correct poor contact between cable clamp and post.

(b) Connect positive lead of the voltmeter to the battery positive post, and negative lead to the battery positive cable clamp. Rotate and hold the ignition switch key in the START position. Observe the voltmeter. If voltage is detected, correct poor contact between the cable clamp and post.

(c) Connect negative lead of voltmeter to battery negative terminal, and positive lead to engine block near the battery cable attaching point. Rotate and hold the ignition switch in the START position. If voltage reads above 0.2 volt, correct poor contact at ground cable attaching point. If voltage reading is still above 0.2 volt after correcting poor contacts, replace ground cable.

(4) Connect positive voltmeter lead to the starter motor housing and the negative lead to the battery negative terminal. Hold the ignition switch key in the START position. If voltage reads above 0.2 volt, correct poor starter to engine ground.

(a) Connect the positive voltmeter lead to the battery positive terminal, and negative lead to battery cable terminal on starter solenoid. Rotate and hold the ignition switch in the START position. If voltage reads above 0.2 volt, correct poor contact at

STARTING (Continued)

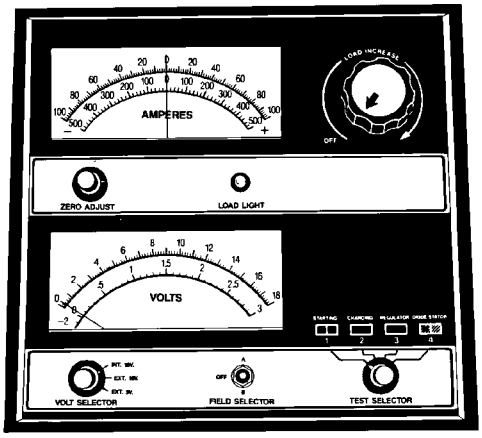
battery cable to solenoid connection. If reading is still above 0.2 volt after correcting poor contacts, replace battery positive cable.

(b) If resistance tests do not detect feed circuit failures, replace the starter motor.

DIAGNOSIS AND TESTING - FEED CIRCUIT TEST

NOTE: The following results are based upon the vehicle being at room temperature.

The following procedure will require a suitable volt-ampere tester (Fig. 1).



898A-8

Fig. 1 Volt Ampere Tester

CAUTION: Before performing any starter tests, the ignition and fuel systems must be disabled.

(1) Check battery before performing this test. Battery must be fully charged.

(2) Connect a volt-ampere tester to the battery terminals. Refer to the operating instructions provided with the tester being used.

(3) To disable the ignition and fuel systems, disconnect the Automatic Shutdown Relay (ASD). The ASD relay is located in the Power Distribution Center (PDC). Refer to the PDC cover for proper relay location.

(4) Verify that all lights and accessories are OFF, and the transmission shift selector is in the PARK and SET parking brake.

CAUTION: Do not overheat the starter motor or draw the battery voltage below 9.6 volts during cranking operations.

(5) Rotate and hold the ignition switch in the START position. Observe the volt-ampere tester (Fig. 1).

- If voltage reads above 9.6 volts, and amperage draw reads above 280 amps, check for engine seizing or faulty starter.
- If voltage reads 12.4 volts or greater and amperage reads 0 to 10 amps, check for corroded cables and/or bad connections.
- Voltage below 9.6 volts and amperage draw above 300 amps, the problem is the starter. Replace the starter refer to starter removal.

(6) After the starting system problems have been corrected, verify the battery state-of-charge and charge battery if necessary. Disconnect all testing equipment and connect ASD relay. Start the vehicle several times to assure the problem has been corrected.

(10) Unlock and disconnect the solenoid electrical connector.

(11) Disconnect and remove the positive battery cable.

(12) Remove the lower starter bolt.

(13) Remove starter (Fig. 17).

STARTER MOTOR (Continued)

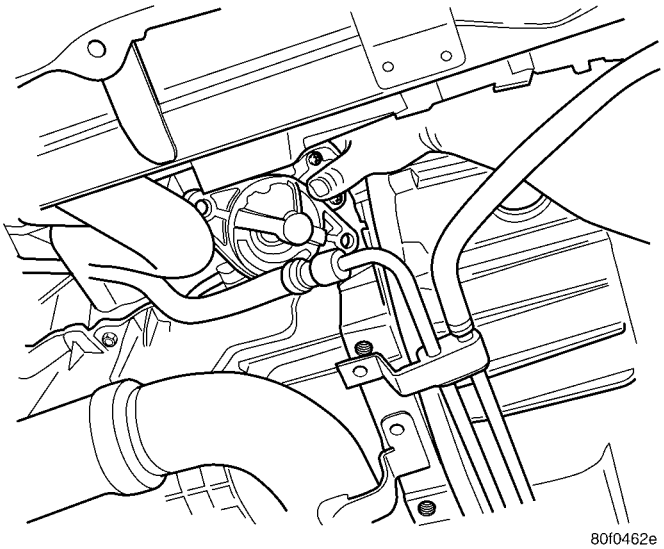

Fig. 17 STARTER REMOVAL/INSTALLATION - 2.4L TURBO

INSTALLATION

INSTALLATION - 1.6L

(1) Install the starter through the wheel well (Fig. 6).
(2) Install the lower mounting bolt.
(3) Install the upper mounting bolts.
(4) Push the spring clip that holds the heat shield for the starter back on the starter solenoid (Fig. 5).
(5) Connect the battery cable (Fig. 4) and solenoid electrical connectors (Fig. 3) to the starter.
(6) Install the exhaust manifold support bracket (Fig. 2).
(7) Lower vehicle.
(8) Connect the negative battery cable.
(9) Install air cleaner cover.

INSTALLATION - 2.2L DIESEL

(1) Install starter (Fig. 8).
(2) Install the upper mounting bolt.
(3) Install the lower mounting bolt and ground cable.
(4) Connect the battery cable to the starter (Fig. 9).
(5) Connect the electrical connectors to the starter (Fig. 9).
(6) Install the radiator to vehicle.
(7) Install radiator to inner cooler, make sure the 2 lower mounting tabs (Fig. 7) lock into the radiator brackets. These tabs are on the bottom of the inner cooler and lock into the bottom of the radiator.
(8) Install the 4 upper bolts for the inner cooler mounting to radiator.
(9) Connect the electrical connector for the radiator fan.
(10) Install the upper radiator hose.
(11) Raise vehicle and support.
(12) Install the 2 lower bolts for the inner cooler mounting to radiator.
(13) Install the lower radiator hose.
(14) Install the underbody plate (skid plate), refer to the Body section for more information.
(15) Lower vehicle.
(16) Install ambient temperature sensor.
(17) Install the upper radiator crossmember.
(18) Install the hood seal, refer to the Body section for more information.
(19) Install the front grill, refer to the Body section for more information.
(20) Connect the negative battery cable.
(21) Fill radiator, refer to the Cooling section for more information.

INSTALLATION - 2.0/2.4L

(1) Reinstall starter motor into vehicle lower engine compartment.
(2) Install starter motor mounting bolts and torque to 54 N·m (40 ft. lbs.).
(3) Connect starter motor wiring. Torque solenoid battery cable nut to 10 N·m (90 in. lbs.).
(4) Install Engine Structural Collar. Refer to Engine, Structural Collar Removal and Installation.

CAUTION:
The torque procedure for the structural collar must be followed, as damage to the oil pan or collar could occur.

(5) Lower vehicle from hoist.
(6) Reconnect battery negative cable.
(7) Reinstall air cleaner box cover.
(8) Verify operation of vehicle and systems.
(9) Close hood and remove from hoist.

INSTALLATION - STARTER 2.4L TURBO

(1) Install starter (Fig. 17).
(2) Install the lower starter bolt and tighten bolt to 54 N·m (40 ft. lbs.).
(3) Connect the positive battery cable and tighten nut to 10 N·m (90 in. lbs.).
(4) Connect and lock the solenoid electrical connector.
(5) Install the Structural Collar, refer to the Engine, Structural Collar Removal and Installation section (Fig. 16).
(6) Locate the power steering lines.
(7) Install the studs that hold the power steering lines and tighten to 61 N·m (45 ft. lbs.).
(8) Tighten nuts that hold the inner cooler lower tube.
(9) Install the inner cooler lower hose to the inner cooler and tighten clamp (Fig. 14).

STARTER MOTOR (Continued)

(10) Lower vehicle.

(11) Pushing the inner cooler hose up and out of the way and install the upper starter bolt and ground wire (Fig. 12) and tighten bolt to 54 N·m (40 ft. lbs.).

(12) Install the air cleaner box.

(13) Tighten air cleaner hose clamp

(14) Connect the negative battery cable.

REAR WINDOW DEFOGGER GRID
STANDARD PROCEDURE
GRID LINE AND TERMINAL REPAIR 5

HEATED GLASS

DESCRIPTION

CAUTION: Grid lines can be damaged or scraped off with sharp instruments. Care should be taken in cleaning glass or removing foreign materials, decals or stickers. Normal glass cleaning solvents or hot water used with rags or toweling is recommended.

The rear window defogger system, also known as electrical backlight (EBL), consists of two vertical bus bars and a series of grid lines fired onto the inside surface of the rear window.

The EBL system is turned ON or OFF by a control switch and a timing circuit, which are combined into a single push-button switch located on the accessory switch bezel (Fig. 1) at the center of the instrument panel (Refer to 8 - ELECTRICAL/HEATED GLASS/ DEFOGGER SWITCH - DESCRIPTION).

Circuit protection is provided by a fuse located in the power distribution center (PDC) for the heated grid circuit, and by a fuse in the junction block (JB) for the control circuit.

OPERATION

The electric backlight (EBL) system is controlled by a momentary switch located in the accessory switch bezel on the instrument panel. When the defogger switch for the EBL system is pressed to the On position, current is directed to the rear defogger grid lines and the heated power mirrors (if equipped). The heated grid lines heat the glass to help clear the rear window and side mirror surfaces of fog or frost.

An amber indicator in the defogger switch will illuminate to indicate when the EBL system is turned on. The rear window defogger switch contains the EBL system control circuitry including the timer logic and the defogger relay.

NOTE: The EBL system turns off automatically after 10 minutes of initial operation. Each following activation cycle of the EBL system will last five minutes.

The EBL system will be automatically turned off after a programmed time interval of about ten minutes. After the initial time interval has expired, if the defogger switch is turned on again during the same ignition cycle, the EBL system will automatically turn off after about five minutes.

HEATED GLASS (Continued)

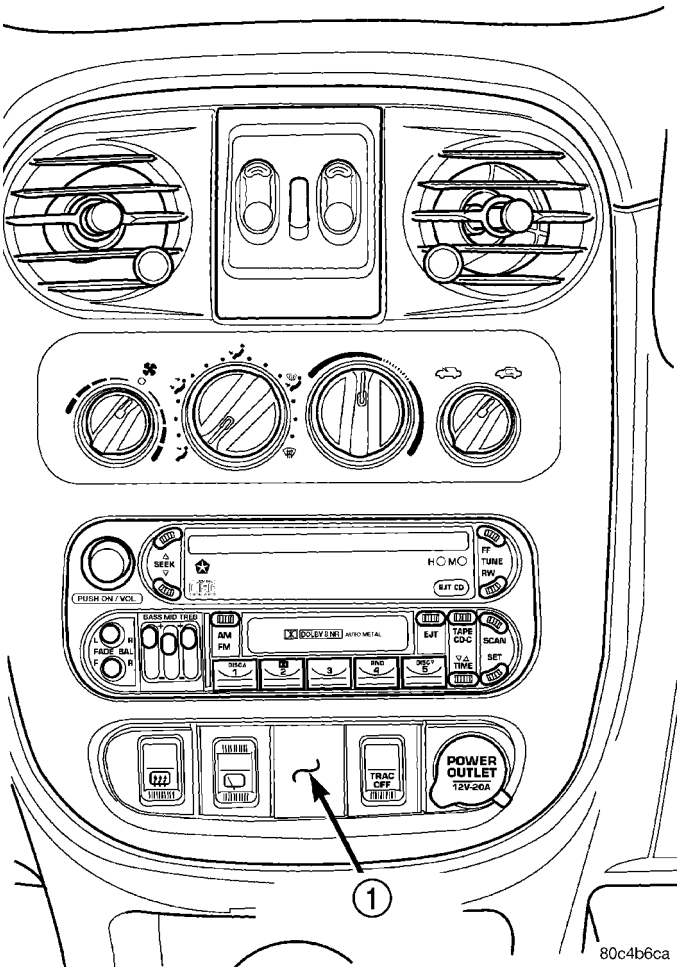

Fig. 1 Rear Window Defogger Switch

1 - ACCESSORY SWITCH BEZEL

The EBL system will automatically shut off if the ignition switch is turned to the Off position, or it can be turned off manually by depressing the defogger switch a second time.

DIAGNOSIS AND TESTING

REAR WINDOW DEFOGGER SYSTEM

NOTE: Illumination of the defogger switch indicator lamp means that there is electrical current available at the output of the rear window defogger logic circuitry, but does not confirm that the electrical current is reaching the rear glass heating grid lines.

NOTE: For circuit descriptions and diagrams of the rear window defogger system, refer to 8W - WIRING DIAGRAM INFORMATION.

Operation of the electrical backlight (EBL) system can be confirmed by the following:

(1) Turn the ignition switch to the On position. Set the defogger switch in the On position. The rear window defogger operation can be checked by feeling the rear window glass. A distinct difference in temperature between the grid lines and the adjacent clear glass can be detected within three to four minutes of operation.

(2) If a temperature difference is not detected, use a 12-volt DC voltmeter and contact the rear glass heating grid terminal B with the negative lead, and terminal A with the positive lead (Fig. 2). The voltmeter should read battery voltage. If the voltmeter does not read battery voltage, check the following:

- Confirm that the ignition switch is in the On position.
- Make sure that the rear glass heating grid feed wire and ground wire are connected to the terminals. Confirm that the ground wire has continuity to ground.
- Check the circuit fuse located in the power distribution center (PDC) and the control circuit fuse in the junction block (JB). The fuses must be tight in their receptacles and all electrical connections must be secure.

(3) When the above steps have been completed and the rear glass heating grid is still inoperative, one or more of the following is faulty:

- Rear window defogger switch.
- Rear window defogger grid lines (all grid lines would have to be broken, or the power feed or ground wire disconnected, for the entire heating grid to be inoperative).

(4) If broken defogger grid lines are suspected, use a 12-volt DC voltmeter and contact terminal B with the negative lead and each rear glass heating grid line at it's mid-point with the positive lead. The voltmeter should read approximately 6 volts at each grid line mid-point C. If the voltmeter does not read approximately 6 volts, repair the open grid line(s) (Refer to 8 - ELECTRICAL/HEATED GLASS/REAR WINDOW DEFOGGER GRID - STANDARD PROCEDURE).

9 - MID-POINT “C”

REAR WINDOW DEFOGGER SWITCH

DESCRIPTION

The switch for the EBL system contains the control and timing circuitry. The rear window defogger switch is located in the accessory switch bezel (Fig. 3) on the instrument panel.

When the rear window defogger switch is turned to the ON position, current is directed to the rear defogger grid lines and the heated power mirrors (if equipped). The heated grid lines heat the glass to help clear the surface of fog or frost.

OPERATION

Depressing the rear window defogger switch energizes the integral rear window defogger relay, which provides electrical current to the rear window defogger grid and the outside rear view mirror heating grids (when equipped). An amber indicator lamp in the defogger switch illuminates to indicate when the EBL system is On.

The rear window defogger switch and indicator lamp cannot be repaired and, if faulty or damaged, the rear window defogger switch must be replaced.

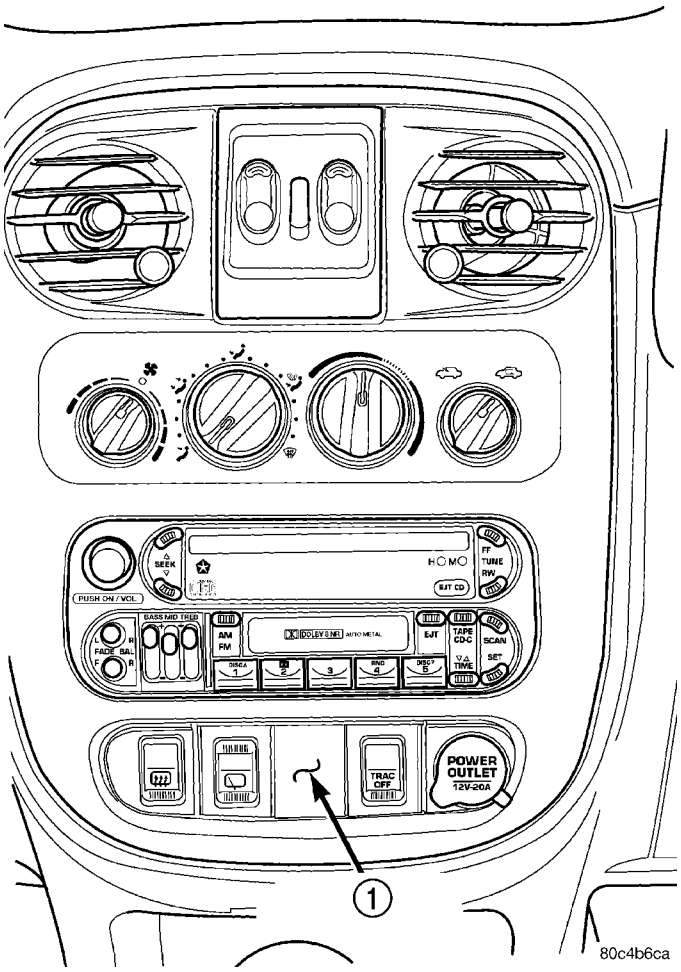

Fig. 3 Rear Window Defogger Switch

1 - ACCESSORY SWITCH BEZEL

DIAGNOSIS AND TESTING

REAR WINDOW DEFOGGER SWITCH

WARNING: On vehicles equipped with airbags, disable the airbag system before attempting any steering wheel, steering column, or instrument panel component diagnosis or service. Disconnect and isolate the battery negative (ground) cable, then wait two minutes for the airbag system capacitor to discharge before performing further diagnosis or service. This is the only sure way to disable the airbag system. Failure to take the proper precautions could result in an accidental airbag deployment and possible personal injury.

NOTE: The rear window defogger switch may be tested in the vehicle or out of the vehicle, on a bench.

REAR WINDOW DEFOGGER SWITCH (Continued)

NOTE: For circuit descriptions and diagrams of the rear window defogger system, refer to 8W - WIRING DIAGRAM INFORMATION.

IN-VEHICLE TESTING

(1) Remove the rear window defogger switch from the instrument panel, but leave the switch connected (Refer to 23 - BODY/INSTRUMENT PANEL/ACCESSORY SWITCH BEZEL - REMOVAL).

(2) Turn the ignition switch ON.

(3) Using a voltmeter, check for battery voltage at Pin 1 and 2 of the rear window defogger switch (Fig. 4).

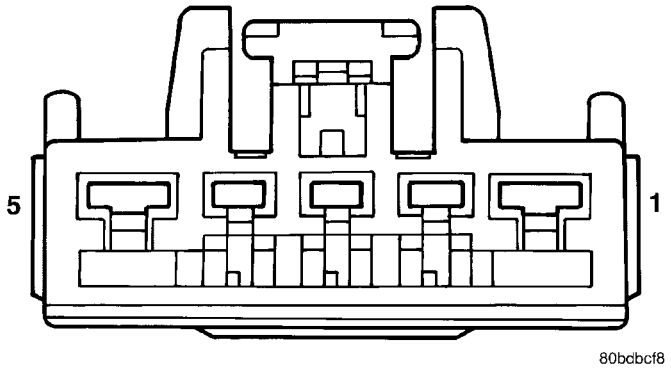

Fig. 4 Rear Window Defogger Switch Harness Connector

REAR WINDOW DEFOGGER SWITCH AND HARNESS CONNECTOR PIN CALL-OUT

PIN	FUNCTION
1	FUSED B+
2	FUSED IGNITION SWITCH OUTPUT (RUN)
3	GROUND
4	PANEL LAMPS DRIVER
5	PANEL LAMPS DRIVER

(a) If OK, go to Step 4.

(b) If NOT OK, check the 10 Amp fuse 6 in the fuse block and the 40 Amp fuse 8 in the power distribution center (PDC). If fuses are OK, check the wiring circuits. Refer to 8W - WIRING DIAGRAM INFORMATION.

(4) Check Pin 5, with switch in the ON position there should be battery voltage and no voltage in the OFF position.

(a) If OK, go to Step 5.

(b) If NOT OK, no voltage in the ON position or voltage in the OFF position. Replace the rear window defogger switch (Refer to 23 - BODY/INSTRUMENT PANEL/ACCESSORY SWITCH BEZEL - INSTALLATION).

(5) Press switch to ON position. The indicator lamp should come on and remain on for approximately 10 minutes. If the indicator lamp fails to light or no voltage is present, replace the rear window defogger switch (Refer to 23 - BODY/INSTRUMENT PANEL/ACCESSORY SWITCH BEZEL - INSTALLATION).

BENCH TESTING

(1) Remove the rear window defogger switch (Refer to 23 - BODY/INSTRUMENT PANEL/ACCESSORY SWITCH BEZEL - REMOVAL).

(2) With switch removed from vehicle, use a jumper wire and connect a 12 volt supply to Pin 1 and 2. Using a third jumper wire, ground Pin 3. Refer to (Fig. 5) and the Rear Window Defogger Switch and Harness Connector Pin Call-Out table.

(3) Follow the same procedures used for IN-VEHICLE TESTING, except for step Step 2.

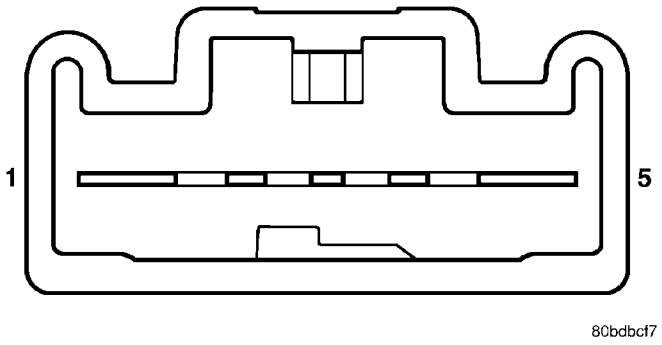

Fig. 5 Rear Window Defogger Switch Connector

REAR WINDOW DEFOGGER GRID

STANDARD PROCEDURE

GRID LINE AND TERMINAL REPAIR

REAR WINDOW DEFOGGER GRID LINE REPAIR

WARNING: Materials contained in the Repair Kit (Part Number 04549275) may cause skin or eye irritation. The kit contains epoxy resin and amine type hardener, which are harmful if swallowed. Avoid contact with the skin and eyes. For skin contact, wash the affected areas with soap and water. For contact with the eyes, flush with plenty of water. Do not take internally. If taken internally, induce vomiting and call a physician immediately. Use with adequate ventilation. Do not use near fire or flame. Contains flammable solvents. Keep out of the reach of children. Failure to follow the warnings could result in possible personal injury or death.

Repair of the rear glass heating grid lines and bus bars can be accomplished using the Mopar® Rear Window Defogger Repair Kit (Part Number 04549275) or equivalent.

(1) Mask the repair area with masking tape or use a template so that the conductive epoxy can be applied neatly (Fig. 6). Extend the epoxy application onto the grid line or the bus bar on each side of the break.

(2) Follow the instructions in the repair kit for preparing the damaged area.

(3) Remove the package separator clamp and mix the two conductive epoxy components thoroughly within the packaging. Fold the package in half and cut the center corner to dispense the epoxy.

(4) Apply the epoxy through the slit in the masking tape or template. Overlap both ends of the break by at least 19 millimeters (0.75 inch).

(5) Apply a thin layer of conductive epoxy to the terminal or bare wire end of the pigtail and place it in the proper location on the bus bar. To prevent the terminal or pigtail wire from moving while the epoxy is curing, it must be wedged or clamped.

(6) Carefully remove the masking tape or template.

CAUTION: Do not allow the glass surface to exceed 204° C (400° F) when using a heat gun, or the glass may fracture.

(7) Allow the epoxy to cure 24 hours at room temperature, or carefully use a heat gun for fifteen minutes. When using a heat gun, hold it approximately 25.4 centimeters (10 inches) from the repair and do not allow the glass surface to exceed 204° C (400° F).

(8) After the conductive epoxy is properly cured, check the operation of the rear window defogger glass heating grid.

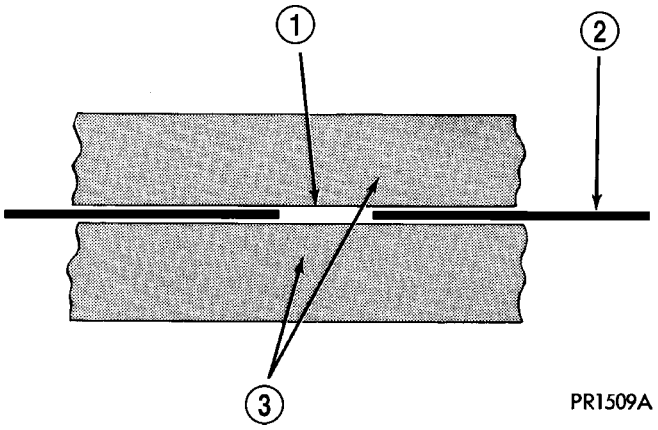

Fig. 6 Grid Line Repair

1 - BREAK
2 - GRID LINE
3 - MASKING TAPE

REAR WINDOW DEFOGGER GRID TERMINAL REPAIR - HARD TOP MODELS

WARNING: Materials contained in the Repair Kit (Part Number 04549275) may cause skin or eye irritation. The kit contains epoxy resin and amine type hardener, which are harmful if swallowed. Avoid contact with the skin and eyes. For skin contact, wash the affected areas with soap and water. For contact with the eyes, flush with plenty of water. Do not take internally. If taken internally, induce vomiting and call a physician immediately. Use with adequate ventilation. Do not use near fire or flame. Contains flammable solvents. Keep out of the reach of children. Failure to follow the warnings could result in possible personal injury or death.

Repair of the rear glass heating grid terminal(s) on hard top models can be accomplished using the Mopar® Rear Window Defogger Repair Kit (Part Number 04549275) or equivalent.

(1) If the grid terminal(s) is broken and a portion of the terminal is still attached to the heating grid, remove the portion of the clip remaining in the wire harness connector(s).

(2) Mask the areas so the conductive epoxy can be extended onto the adjacent grid line(s) as well as the bus bar.

(3) Apply a thin layer of conductive epoxy to the area where the terminal(s) where fastened and to the adjacent grid line(s).

REAR WINDOW DEFOGGER GRID (Continued)

NOTE: To prevent the terminal(s) from moving while the epoxy is curing, a wedge or clamp must be used.

(4) Apply a thin layer of conductive epoxy on the terminal(s) and properly orient the terminal(s) at the desired location(s).

(5) Carefully remove the masking tape.

CAUTION: Do not allow the glass surface to exceed 204° C (400° F) when using a heat gun, or the glass may fracture.

(6) Allow the epoxy to cure 24 hours at room temperature, or carefully use a heat gun for fifteen minutes. When using a heat gun, hold it approximately 25.4 centimeters (10 inches) from the repair and do not allow the glass surface to exceed 204° C (400° F).

NOTE: To ensure proper installation, do not attach the wire harness connector(s) to the terminal(s) until the epoxy is completely cured.

(7) After the conductive epoxy has properly cured, remove the wedge or clamp from the terminal(s), reconnect the wire harness connector(s) and verify operation of the rear window defogger.

REAR WINDOW DEFOGGER GRID TERMINAL REPAIR - CONVERTIBLE MODELS

CAUTION: Do not use a flame type solder gun or an electric solder gun rated greater than 500 watts or damage to the glass may occur.

If the rear window defogger grid terminal(s) on convertible models is damaged or separated from the rear window, the new grid terminal(s) must be securely fastened to the rear window defogger bus bar by soldering.

(1) If the grid terminal(s) is broken and a portion of the terminal is still attached to the heating grid, remove the portion of the clip remaining in the wire harness connector(s).

CAUTION: Do not allow the glass surface to exceed 204° C (400° F) when using a solder gun, or the glass may fracture.

(2) If the grid terminal(s) is broken and a portion of the terminal is still attached to the rear window defogger bus bar, apply heat with a solder gun to the portion of the terminal on the glass until the solder starts to flow. Remove the terminal and carefully smooth the solder on the bus bar.

NOTE: Wait five minutes for the glass to cool after applying heat with a solder gun before proceeding.

NOTE: Use care when cleaning the mating surfaces. Excessive abrasion may wear away the copper grid surface causing grid continuity to be lost.

(3) Clean the mating surfaces on the grid bus bar and the new terminal(s) with “000” Extra Fine Steel Wool or an equivalent.

NOTE: The terminal attaching clip(s) must face outboard. Failure to reorient the terminal(s) may result in an additional failure.

(4) Properly orient the new terminal(s) with the attaching clip facing outboard in the original location(s) on the grid bus bar and hold the terminal(s) with a metal pick or other suitable pointed tool.

CAUTION: Do not allow the glass surface to exceed 204° C (400° F) when using a solder gun, or the glass may fracture.

NOTE: New rear window defogger terminals are presoldered and fluxed. Do not reuse a terminal if it has been previously heated.

Place the solder gun onto the new terminal(s) and heat the terminal until the solder flows. Remove the solder gun and continue to hold the terminal in the correct position for an additional five seconds.

(5) Allow the solder to cool for ten minutes.

NOTE: To ensure proper installation, do not attach the wire harness connector(s) to the terminal(s) until the solder is completely cooled.

(6) After the solder has cooled, reconnect the wire harness connector(s) and verify operation of the rear window defogger.

HEATED MIRRORS

TABLE OF CONTENTS

	page
HEATED MIRRORS	
DESCRIPTION	7
OPERATION	7

HEATED MIRRORS

DESCRIPTION

The optional heated mirror system is controlled by the momentary rear window defogger switch on the accessory switch bezel (Fig. 1). An amber indicator lamp in the switch will illuminate to indicate when the rear window defogger (EBL) system is turned on.

The heated mirror system only operates in concert with the EBL system, and will be automatically shut off after a programmed time interval of about 10 minutes. After the initial time interval has expired, if the defogger switch is turned on again during the same ignition cycle, the heated mirror system will automatically shut off after about 5 minutes.

The heated mirror system will automatically shut off if the ignition switch is turned to the Off position, or it can be shut off manually by pressing the rear window defogger switch a second time.

OPERATION

When the rear window defogger switch is pressed, the rear window defogger (EBL) system becomes activated and an electric heater grid located behind the glass of each of the outside rear view mirrors is energized. When energized, each of these heater grids produce heat to help clear the outside rear view mirrors of ice, snow, or fog.

If the outside mirror heating grids are both inoperative, refer to DIAGNOSIS AND TESTING - REAR WINDOW DEFOGGER SYSTEM in his group. If only one of the outside mirror heating grids is inoperative, Refer to 8 - ELECTRICAL/POWER MIRRORS - DIAGNOSIS AND TESTING.

The heating grid behind each outside mirror glass cannot be repaired and, if faulty or damaged, the entire power mirror assembly must be replaced.

HEATED SEAT SYSTEM

DESCRIPTION

Individually controlled, electrically heated front seats are available as factory-installed equipment on this model. Vehicles with this option can be visually identified by the two separate heated seat switches mounted on each of the seat cushion side shields. The heated seat system allows the front seat driver and passenger to select from two different levels of supplemental electrical seat heating, or no seat heating to suit their individual comfort requirements.

WARNING: SOME VEHICLES ARE EQUIPPED WITH SEATBACK MOUNTED AIRBAGS (Fig. 1). BEFORE ATTEMPTING TO DIAGNOSE OR SERVICE ANY SEAT OR POWER SEAT SYSTEM COMPONENT YOU MUST FIRST DISCONNECT AND ISOLATE THE BATTERY NEGATIVE CABLE. THEN WAIT TWO MINUTES FOR THE SYSTEM CAPACITOR TO DISCHARGE BEFORE FURTHER SYSTEM SERVICE. THIS IS THE ONLY SURE WAY TO DISABLE THE AIRBAG SYSTEM. FAILURE TO DO SO COULD RESULT IN ACCIDENTAL AIRBAG DEPLOYMENT AND POSSIBLE PERSONAL INJURY.

The heated seat system for this vehicle includes the following major components, which are described in further detail later in this section:

- **Heated Seat Elements** - Four heated seat elements are used per vehicle, two for each front seat. One heating element in the seat back and one in the seat cushion. The heated seat sensor is integral to the seat cushion heating element. The heated seat elements are integral to the front seat and seat back cushions. Refer to heated seat elements later in this section for additional information.
- **Heated Seat Module** - One heated seat module is used per vehicle. The module is mounted under the driver seat cushion pan, near the forward edge of the seat. Refer to heated seat module in the electronic control modules section of the service manual for additional information.
- **Heated Seat Relay** - One heated seat relay is used per vehicle. The relay is located in the junction block and is responsible for distributing the voltage (B+) to the heated seat system.

HEATED SEAT SYSTEM (Continued)

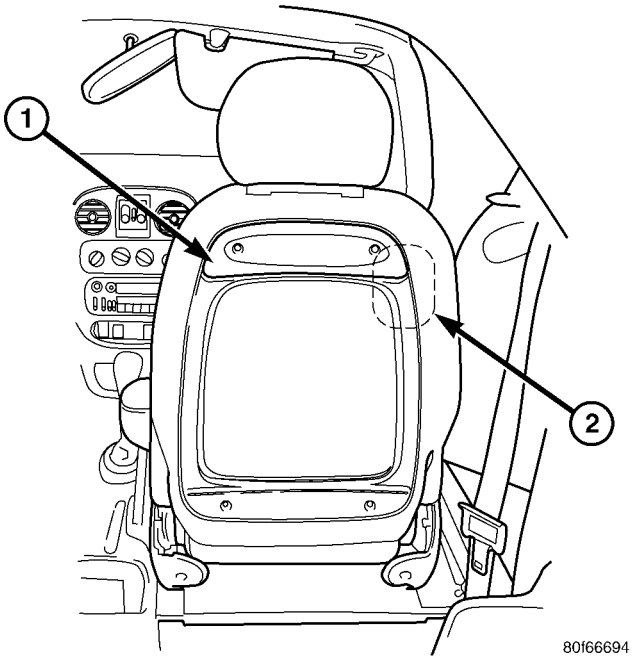

Fig. 1 Front Seats Equipped With Airbag

1 - FRONT SEAT BACK PANEL
2 - INTERNAL AIRBAG LOCATION

- **Heated Seat Sensors** - Two heated seat sensors are used per vehicle, one for each front seat. The heated seat sensors are integral to each of the heated seat element assemblies. Refer to heated seat sensor later in this section for additional information.
- **Heated Seat Switches** - Two heated seat switches are used per vehicle, one for each front seat. The switches are mounted to each of the outboard front seat cushion side shields. Refer to heated seat switches later in this section for additional information.

Hard wired circuitry connects the heated seat system components to each other through the electrical system of the vehicle. These hard wired circuits are integral to wire harnesses, which are routed throughout the vehicle and retained by many different methods. These circuits may be connected to each other, to the vehicle electrical system and to the heated seat system components through the use of a combination of soldered splices, splice block connectors and different types of wire harness terminal connectors. Refer to the appropriate wiring information. The wiring information includes wiring diagrams, proper wire and connector repair procedures, further details on wire harness routing and retention, as well as pin-out and location views for the various wire harness connectors, splices and grounds.

OPERATION

The heated seat system is designed to provide individually controlled, supplemental heat to the seat cushion and seat back surfaces of both front seats. Because this system converts electrical current to heat, the heated seat system can provide a measure of warm comfort almost immediately upon entering a cold vehicle, rather than having to wait for the engine coolant to reach sufficient temperature to deliver heat through the conventional heater system. This system allows each front seat occupant to individually select one of two comfort levels, Hi or Lo, or to turn the heater for their seat off.

The heated seat system components operate on battery current received through a fuse in the Junction Block (JB) on a fused ignition switch output (run-acc) circuit so that the system will only operate when the ignition switch is in the On or Accessory positions. The heated seat system will be turned Off automatically whenever the ignition switch is turned to any position except On or Accessory. Also, the heated seat system will not operate when the surface temperature of the seat cushion cover at either heated seat sensor is above the designed temperature set points of the system. The heated seat system has a self-diagnostic capability. When certain failures are detected within the heated seat system, the system will provide a visual indication of the failure by flashing the Light Emitting Diode (LED) indicator lamps located in the heated seat switches. See the owner's manual in the vehicle glove box for more information on the features, use and operation of the heated seat system.

DIAGNOSIS AND TESTING - HEATED SEAT SYSTEM

Refer to **Wiring Diagrams** for the appropriate wiring information. The wiring information includes wiring diagrams, proper wire and connector repair procedures, further details on wire harness routing and retention, as well as pin-out and location views for the various wire harness connectors, splices and grounds.

HEATED SEAT SYSTEM (Continued)

HEATED SEAT SYSTEM DIAGNOSIS		
CONDITION	POSSIBLE CAUSES	CORRECTION
NO HEATED SEAT SWITCH ILLUMINATION WITH IGNITION ON	1. Faulty fuse.	1. Check heated seat fuse in Junction Block (JB). Replace fuse, if required.
	2. Wiring faulty.	2. Check fused ignition switch output (run-acc) circuit from heated seat switch connector to ignition switch. Repair, if required.
	3. Ground faulty.	3. Check for ground at heated seat switch connector. Repair, if required.
	4. Faulty switch.	4. Refer to Heated Seat Switch for the proper switch diagnosis and testing procedures.
SEATS HEAT, BUT NO HEATED SEAT SWITCH INDICATORS	1. Wiring faulty.	1. Check LED driver circuit(s) from heated seat switch connector to heated seat module connector. Repair, if required.
	2. Faulty switch LED.	2. Replace switch with known good unit. If OK, discard faulty switch.
	3. Faulty module.	3. Refer to Heated Seat Module for the proper module diagnosis and testing procedures. Replace, if required.
SEATS DO NOT HEAT AND NO HEATED SEAT SWITCH INDICATORS	1. Faulty circuit breaker.	1. Check power seat circuit breaker in Junction Block (JB). Replace, if required.
	2. Faulty relay.	2. Refer to Heated Seat Relay for the proper relay diagnosis and testing procedures. Replace, if required.
	3. Faulty module.	3. Refer to Heated Seat Module for the proper module diagnosis and testing procedures. Replace, if required.
HEATED SEAT SWITCH INDICATORS FLASHING	1. Faulty sensor.	1. Refer to Heated Seat Sensor for the proper heated seat system self-diagnostic routine. Repair, as required.
	2. Faulty element.	2. Refer to Heated Seat Element for the proper heated seat system self-diagnostic routine. Repair, as required.

SELF-DIAGNOSTICS - HEATED SEAT SYSTEM

The heated seat system is capable of performing some self-diagnostics. The following table depicts the various failure modes which will be reported to the occupant via flashing of the heated seat switch Light-Emitting Diode (LED) indicators. Flashing LED indicators on the driver side switch indicate that a fault exists in the driver side of the system and, likewise, flashing LED indicators on the passenger side switch indicate a fault exists in the passenger side of the system. The LED indicators will flash at a rate of approximately one-half second on, and one-half second off for a duration of one minute. This process will repeat each time an attempt is made to turn the system on with the heated seat switches until the problem has been corrected.

DRIVER HEATED SEAT SWITCH

DESCRIPTION

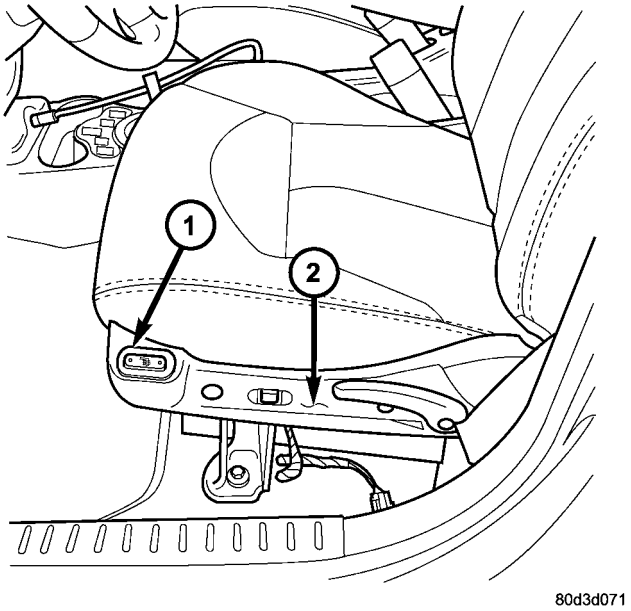

Fig. 2 PT Heated Seat Switch Location

1 - HEATED SEAT SWITCH
2 - SEAT CUSHION SIDE SHIELD

The heated seat switches are located on the outboard cushion side shield of the driver (Fig. 2) and passenger seats. The two, momentary rocker type switches provide a resistor multiplexed signal to the Heated Seat Module (HSM) through separate hard wired circuits. Each switch contains two light emitting diodes (LED), one for each High and Low setting to let the occupant know that the seat heater system is on.

The heated seat switches and their LED's cannot be repaired. If either switch is faulty or damaged the entire switch must be replaced.

OPERATION

There are three modes that can be selected with each of the heated seat switches: Off, Low, and High. When the front of the switch rocker is depressed, the High mode is selected and the high mode LED indicator illuminates. Depressing the front of the switch rocker a second time will turn the heated seat to Off. When the rear of the switch rocker is depressed, the Low mode is selected and the low mode LED indicator illuminates. Depressing the rear of the switch rocker a second time will also turn the heated seat to Off. In addition, the heated seats will automatically return to the Off mode anytime the vehicle ignition switch is turned Off.

Both switches provide separate resistor multiplexed hard wire inputs to the Heated Seat Module to indicate the selected mode. The Heated Seat Module responds to the heated seat switch status messages by controlling the output to the seat heater elements of the selected seat. The Low heat position set point is about 36° C (97° F), and the High heat position set point is about 41° C (105° F).

DIAGNOSIS AND TESTING - DRIVER HEATED SEAT SWITCH

For circuit description and diagrams, refer to **Wiring Diagrams**.

Inspect the Heated Seat Switches for apparent damage or sticking/binding and replace if required. Refer to Heated Seat Switch Removal and Installation in this section.

Using an ohmmeter, check the continuity between pin 4 and pin 6 of the switch. Measure the resistance between the two pins while depressing the appropriate button. Refer to (Fig. 3) and the Heated Seat Switch Pin Call-Out table. If the readings do not correspond to those in the Heated Seat Switch Continuity table, replace the heated seat switch.

REMOVAL

(1) Disconnect and isolate the negative battery cable remote terminal from the remote battery post.

(2) Remove the appropriate seat cushion side shield. Refer to the Body section of this manual for the procedure.

(3) Working from the underside of the switch, gently rock the switch back and forth out of its mounting location.

INSTALLATION

(1) Gently rock the switch back and forth in to its mounting location.

(2) Install the appropriate seat cushion side shield. Refer to the Body section of this manual for the procedure.

(3) Connect the remote negative battery cable.

HEATED SEAT ELEMENT

DESCRIPTION

The heated seat system includes two seat heating elements in each front seat, one for the seat cushion (Fig. 4) and the other for the seat back. All models use two carbon fiber mesh heating elements for each seat that are connected in parallel with the Heated Seat Module (HSM). The temperature sensor is a Negative Temperature Coefficient (NTC) thermistor. One temperature sensor is used for each seat, and it is located in the seat cushion heating element for all models.

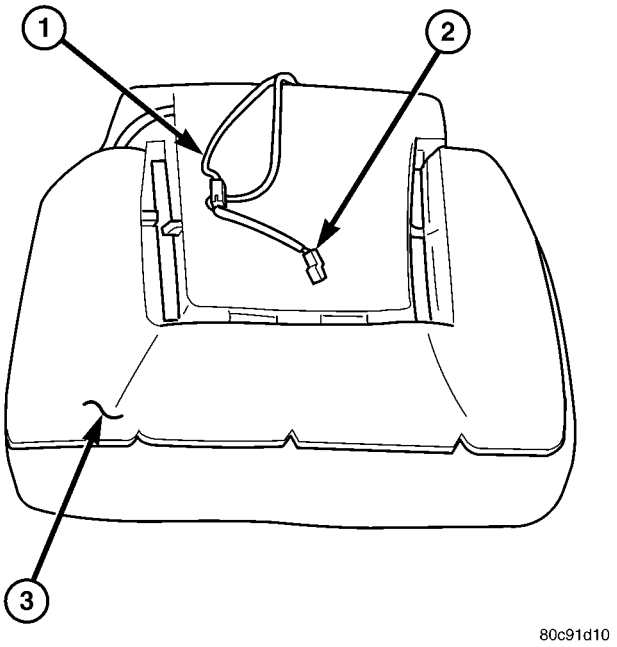

Fig. 4 Heated Seat Element - Typical

1 - SEAT BACK WIRE HARNESS
2 - HEATED SEAT WIRE HARNESS CONNECTOR
3 - HEATED SEAT CUSHION ELEMENT

The seat heating elements are glued onto the seat and seat back cushions. The heated seat elements and the temperature sensor cannot be adjusted or repaired and, if faulty or damaged a new service part must be installed. Refer to the procedure in this section.

HEATED SEAT ELEMENT (Continued)

OPERATION

The heated seat elements resist the flow of electrical current. When battery current is passed through the elements, the energy lost by the resistance of the elements is released in the form of heat. The temperature sensor is a NTC thermistor. The heated seat module supplies a five-volt current to one side of each sensor, and monitors the voltage drop through the sensor on a return circuit. When the temperature of the seat cushion cover rises, the resistance of the sensor decreases. The heated seat module uses this temperature sensor input to monitor the temperature of the seat, and regulates the current flow to the seat heating elements accordingly.

DIAGNOSIS AND TESTING - HEATED SEAT ELEMENT

For complete circuit diagrams, refer to **Wiring Diagrams**.

NOTE: When checking heated seat elements for continuity, be certain to move the heating element being checked. Moving the element, such as sitting in the seat will eliminate the possibility of an intermittent open in the element which would only be evident if the element was in a certain position. Failure to check the element in various positions could result in an incomplete test.

(1) Disconnect and isolate the battery negative cable. Disconnect the heated seat module wire harness connector. Check for continuity between the seat heater B+ driver circuit cavity and a good ground, preferably under the seat. There should be continuity, less than 7 ohms. If OK, go to Step 2. If not OK, replace the heating element assembly.

(2) Check for continuity between the seat heater B+ driver circuit cavity and the seat back frame. There should be **no** continuity. If OK, go to Diagnosis and Testing the heated Seat Module in the electronic control modules section of this service manual for additional diagnostics. If not OK, replace the element as required.

REMOVAL

Do not attempt to remove the heating element from the seat or seat back cushion. The original element is permanently attached to the seat cushions and cannot be removed without damaging the cushion. The service replacement (if available) heating elements are designed to be applied directly over the original seat heating elements.

(1) Disconnect and isolate the negative battery cable.

(2) Remove the appropriate seat cushion or seat back trim cover. Refer to the Body section of the service manual for the procedures.

(3) Disconnect the inoperative heated seat cushion or seat back element electrical connectors.

(4) Locate the wires leading from the inoperative heating element and cut them off flush with the edge of the original heating element.

INSTALLATION

(1) Peel off the adhesive backing on the back of the replacement heating element and stick directly over the original heating element (Fig. 5).

CAUTION: During the installation of the replacement heating element, be careful not to fold or crease the element assembly. Folds or creases will cause premature failure.

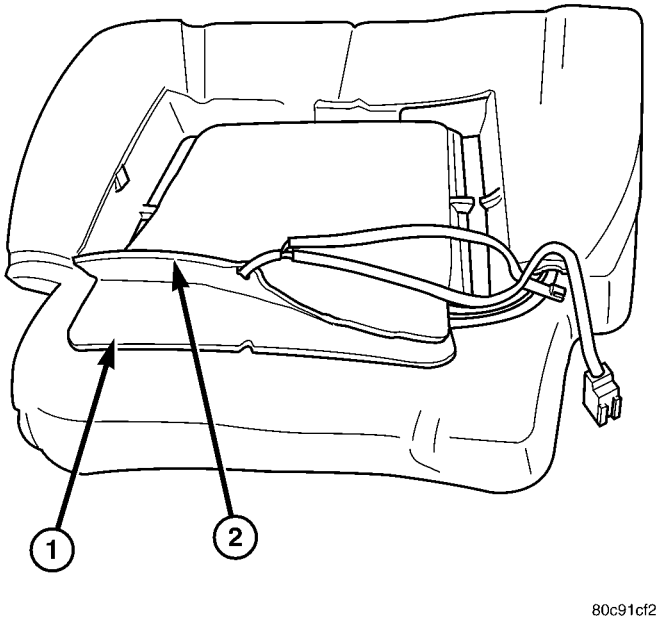

Fig. 5 Heated Seat Element Installation

1 - ORIGINAL (INOPERATIVE) HEATING ELEMENT
2 - REPLACEMENT HEATING ELEMENT

(2) Connect the new heating element electrical connectors (Fig. 6).

(3) Connect the negative battery cable.

(4) Verify heated seat system operation.

(5) Install the appropriate seat cushion or seat back trim cover. Make certain the seat wire harness is correctly routed through the seat and seat back. The excess wire between the cushion and back elements should be securely tucked between the rear of the cushion foam and the rear carpet flap of the trim cover.

HEATED SEAT ELEMENT (Continued)

HEATED SEAT RELAY

DESCRIPTION

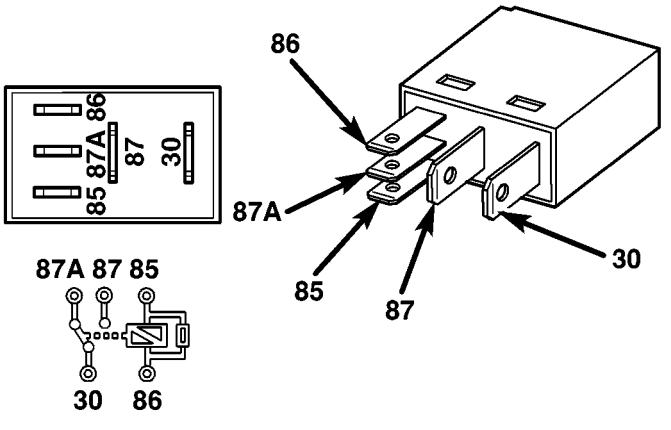

Fig. 7 ISO Micro Relay

30 - COMMON FEED
85 - COIL GROUND
86 - COIL BATTERY
87 - NORMALLY OPEN
87A - NORMALLY CLOSED

A micro-relay is a conventional International Standards Organization (ISO) micro relay (Fig. 7). Relays conforming to the ISO specifications have common physical dimensions, current capacities, terminal patterns, and terminal functions. The relay is contained within a small, rectangular, molded plastic housing and is connected to all of the required inputs and outputs by five integral male spade-type terminals that extend from the bottom of the relay base.

Relays cannot be adjusted or repaired and, if faulty or damaged, the unit must be replaced.

OPERATION

A micro-relay is an electromechanical switch that uses a low current input from one source to control a high current output to another device. The movable common feed contact point is held against the fixed normally closed contact point by spring pressure. When the relay coil is energized, an electromagnetic field is produced by the coil windings. This electromagnetic field draws the movable relay contact point away from the fixed normally closed contact point, and holds it against the fixed normally open contact point. When the relay coil is de-energized, spring pressure returns the movable contact point back against the fixed normally closed contact point. A resistor is connected in parallel with the relay coil in the relay, and helps to dissipate voltage spikes and electromagnetic interference that can be generated as the electromagnetic field of the relay coil collapses.

DIAGNOSIS AND TESTING - HEATED SEAT RELAY

(1) Remove the relay from its mounting location.

(2) A relay in the de-energized position should have continuity between terminals 87A and 30, and no continuity between terminals 87 and 30. If OK, go to Step 3. If not OK, replace the faulty relay.

(3) Resistance between terminals 85 and 86 (electromagnet) should be 67.5 - 82.5 ohms. If OK, go to Step 4. If not OK, replace the faulty relay.

(4) Connect a battery to terminals 85 and 86. There should now be continuity between terminals 30 and 87, and no continuity between terminals 87A and 30. If OK, relay is OK at this time. Refer to the appropriate diagnostic information for further testing.

Refer to the appropriate wiring information. The wiring information includes wiring diagrams, proper wire and connector repair procedures, details of wire harness routing and retention, connector pin-out information and location views for the various wire harness connectors, splices and grounds.

REMOVAL

(1) Remove the relay by grasping it firmly and pulling it straight out from its receptacle.

HEATED SEAT RELAY (Continued)

INSTALLATION

(1) Align the micro-relay terminals with the terminal cavities in the receptacle.

(2) Push firmly and evenly on the top of the relay until the terminals are fully seated in the terminal cavities in the receptacle.

HEATED SEAT SENSOR

DESCRIPTION

The heated seat temperature sensor is a Negative Temperature Coefficient (NTC) thermistor. One temperature sensor is used for each seat. The sensor is located in the seat cushion heating element for all models.

The heated seat sensor cannot be adjusted or repaired and if it is found to be faulty, the complete heated seat element must be replaced.

OPERATION

The temperature sensor is a NTC thermistor. The heated seat module supplies a five-volt current to one side of each sensor, and monitors the voltage drop through the sensor on a return circuit. When the temperature of the seat cushion cover rises, the resistance of the sensor decreases. The heated seat module uses this temperature sensor input to monitor the temperature of the seat, and regulates the current flow to the seat heating elements accordingly.

DIAGNOSIS AND TESTING - HEATED SEAT SENSOR

For complete circuit diagrams, refer to **Wiring Diagrams**.

NOTE: Any resistance values (ohms Ω) given in the following text are supplied using the automatic range generated by a FLUKE® automotive meter. If another type of measuring device is used the values generated may not be the same as the results shown here, or may have to be converted to the range used here.

(1) Position the driver seat in the full rearward position.

(2) Backprobe the heated seat module wire harness connector, do not disconnect. Disconnecting the module will disable the entire heated seat system. Using an voltmeter, check the voltage of the seat temperature sensor input cavity of the heated seat module wire harness connector. The seat sensor input voltage should be between 1.7 volts and 3.0 volts with the system ON. If OK, go to Step 3. If not OK, replace the faulty seat cushion heating element and sensor assembly.

(3) Test the seat wire harness between the heated seat module connector and the heated seat wire harness connector for shorted or open circuits. If OK, refer to **Diagnosis and Testing the Heated Seat Module** in Electronic Control Modules, for the proper heated seat module diagnosis and testing procedures. If not OK, repair the shorted or open heated seat wire harness as required.

REMOVAL

(1) For heated seat sensor replacement procedure (Refer to 8 - ELECTRICAL/HEATED SEATS/ HEATED SEAT ELEMENT - REMOVAL).

PASSENGER HEATED SEAT SWITCH

DESCRIPTION

The heated seat switches are located on the outboard cushion side shield of the driver and passenger seats. The two, momentary rocker type switches provide a resistor multiplexed signal to the Heated Seat Module (HSM) through separate hard wired circuits. Each switch contains two light emitting diodes (LED), one for each High and Low setting to let the occupant know that the seat heater system is on.

The heated seat switches and their LED's cannot be repaired. If either switch is faulty or damaged the entire switch must be replaced.

OPERATION

There are three modes that can be selected with each of the heated seat switches: Off, Low, and High. When the front of the switch rocker is depressed, the High mode is selected and the high mode LED indicator illuminates. Depressing the front of the switch rocker a second time will turn the heated seat to Off. When the rear of the switch rocker is depressed, the Low mode is selected and the low mode LED indicator illuminates. Depressing the rear of the switch rocker a second time will also turn the heated seat to Off. In addition, the heated seats will automatically return to the Off mode anytime the vehicle ignition switch is turned Off.

Both switches provide separate resistor multiplexed hard wire inputs to the Heated Seat Module to indicate the selected mode. The Heated Seat Module responds to the heated seat switch status messages by controlling the output to the seat heater elements of the selected seat. The Low heat position set point is about 36° C (97° F), and the High heat position set point is about 41° C (105° F).

PASSENGER HEATED SEAT SWITCH (Continued)

DIAGNOSIS AND TESTING - PASSENGER HEATED SEAT SWITCH

For circuit description and diagrams, refer to **Wiring Diagrams**.

Inspect the Heated Seat Switches for apparent damage or sticking/binding and replace as required. Refer to Heated Seat Switch Removal and Installation in this section.

Using an ohmmeter, check the continuity between pin 4 and pin 6 of the switch. Measure the resistance between the two pins, while depressing the appropriate buttons. Refer to (Fig. 8)and the Heated Seat Switch Pin Call-Out table. If the readings do not correspond to those in the Heated Seat Switch Continuity table, replace the heated seat switch.

REMOVAL

(1) Disconnect and isolate the negative battery cable remote terminal from the remote battery post.

(2) Remove the appropriate seat cushion side shield. Refer to the Body section of this manual for the procedure.

(3) Working from the underside of the switch, gently rock the switch back and forth out of its mounting location.

INSTALLATION

(1) Gently rock the switch back and forth in to its mounting location.

(2) Install the appropriate seat cushion side shield. Refer to the Body section of this manual for the procedure.

(3) Connect the remote negative battery cable.

HEATED SEAT MODULE

DESCRIPTION

One heated seat module is used per vehicle to control both front heated seats. The heated seat module (Fig. 9) is located on the driver seat cushion pan, where it is secured with two push-in type plastic fasteners. The module is encased within a small, rectangular, molded plastic housing with a single connector receptacle that allows it to be connected to all of the required inputs and outputs through the power seat wire harness.

The heated seat module is a electronic microprocessor controlled device that is designed to monitor the inputs and control the outputs of the heated seat system. The heated seat module is programmed to provide two levels of heating for each front seat. The Low temperature set point is about 36° C (97° F) and the High temperature set point is about 41° C (105° F). The heated seat module is also programmed to perform some self-diagnosis. If the module detects a shorted or open heating element or a NTC heated seat sensor out of range the module will flash the heated seat switch indicator LED's, to inform the mechanic or operator that a problem exists with the

HEATED SEAT MODULE (Continued)

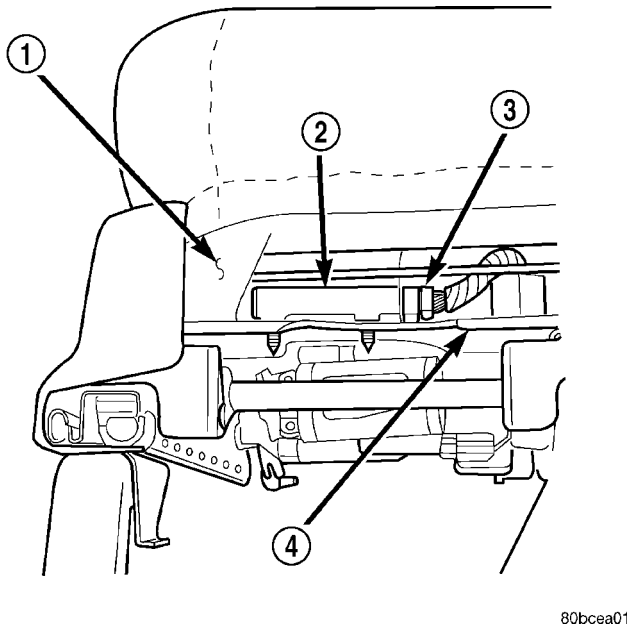

Fig. 9 Heated Seat Module Location - Typical

1 - SEAT CUSHION FRAME
2 - HEATED SEAT MODULE
3 - WIRE HARNESS CONNECTOR
4 - POWER SEAT TRACK FRONT BRACKET

heated seat system. Refer to heated seat system diagnosis and testing for additional information.

The heated seat module cannot be adjusted or repaired. If a module is damaged or faulty, the entire module must be replaced.

OPERATION

The heated seat module operates on battery current received through a fuse in the Junction Block (JB) on a fused ignition switch output (run-acc) circuit so that the heated seat system will only operate when the ignition switch is in the On or Accessory positions. The heated seat module is grounded at all times through a ground feed from a two wire take out and eyelet terminal connector of the power seat wire harness that is secured by a ground screw to the top of the seat crossmember under each front seat. Inputs to the heated seat module include a seat heater switch MUX circuit for each of the two heated seat switches, heated seat sensor inputs from the seat cushions of each front seat, and battery current from the power seat circuit breaker in the JB received through the energized heated seat relay on two heated seat relay output circuits. Outputs from the heated seat module include a battery voltage reference to the heated seat sensors on a sensor feed circuit, a battery current feed to the two heated seat element circuits on separate heated seat driver circuits, and separate Lo and Hi driver circuits for each of the heated seat switch Light-Emitting Diode (LED) indicator lamps.

When a driver or passenger heated seat switch request signal is received by the heated seat module, the module energizes the proper switch LED indicator lamp (Lo or Hi) by pulling the LED driver circuit to ground. This provides an indication to the vehicle operator that the heated seat system is operating and whether the Hi or Lo heat mode is selected. At the same time, the heated seat module energizes the heated seat sensor feed circuit and the sensor provides the module with a heat sense input indicating the surface temperature of the selected seat cushion. If the seat cushion surface temperature input is below the temperature set point for the selected heat mode, the heated seat module energizes an N-channel Field Effect Transistor (N-FET) within the module. The N-FET switches battery current to the heated seat elements in the selected seat cushion and back. When the heated seat sensor input indicates the correct temperature set point has been achieved, the heated seat module de-energizes the N-FET which switches off the battery current to the heated seat elements. The heated seat module will continue to cycle the N-FET as needed to maintain the selected temperature set point.

If the heated seat module detects a heated seat sensor value input that is out of range or a shorted or open heated seat element circuit, it will automatically de-energize the N-FET and switch off the battery current to the affected heated seat elements. The heated seat module will also notify the vehicle operator or the repair technician of this condition by flashing the Hi and/or Lo LED indicator lamps in the affected heated seat switch in a prescribed sequence as a self-diagnostic feedback. Refer to Diagnosis and Testing for the proper heated seat system diagnosis and testing procedures.

DIAGNOSIS AND TESTING - HEATED SEAT MODULE

Refer to the appropriate wiring information in **Wiring Diagrams**. The wiring information includes wiring diagrams, proper wire and connector repair procedures, further details on wire harness routing and retention, as well as pin-out and location views for the various wire harness connectors, splices and grounds.

(1) If a heated seat fails to heat and one or both of the LED indicator lamps on a heated seat switch flash, refer to **Heated Seat System Diagnosis and Testing**.

(2) Test the appropriate Heated Seat Switch, refer to the procedure in the Heated Seats section of this manual.

(3) Test the Heated Seat Sensor, refer to the procedure in the Heated Seats section of this manual.

HEATED SEAT MODULE (Continued)

(4) Test the Heated Seat Element, refer to the procedure in the Heated Seats section of this manual.

(5) Disconnect the heated seat module connector receptacle. Using an ohmmeter, check for continuity between the **ground circuit** cavity and a good ground. If OK, go to Step 6. If not OK, repair the open ground circuit to ground as required.

(6) Disconnect the heated seat module connector receptacle. Using an voltmeter, check for voltage on the **B+ circuit** cavity. If OK, go to Step 7. If not OK, repair the open B+ circuit as required.

(7) Replace the heated seat module with a known good module. Test operation of the heated seat system. If system works, OK repair complete. If system is still inoperative a short or open exists in the heated seat system wiring. Using Wiring Diagrams as a guide, check the individual circuits until the short or open is found.

REMOVAL

WARNING: THERE ARE MANY SHARP METAL EDGES ON THE SEAT CUSHION FRAME AND SEAT ADJUSTER RAILS UNDER THE SEAT. WHEN PERFORMING THIS SERVICE, A LONG-SLEEVED SHIRT AND GLOVES SHOULD BE WORN IN ORDER TO AVOID UNNECESSARY CUTS AND ABRASIONS TO EXPOSED SKIN.

(1) Move the driver power seat to its full up and full rear stop positions.

(2) Disconnect and isolate the battery negative cable.

(3) Working under the seat, release the two plastic push-in fasteners from either the module or the mounting holes in the power seat cushion pan (Fig. 10).

(4) Disconnect the power seat wire harness connector from the heated seat module connector receptacle.

(5) Remove the heated seat module from the power seat track.

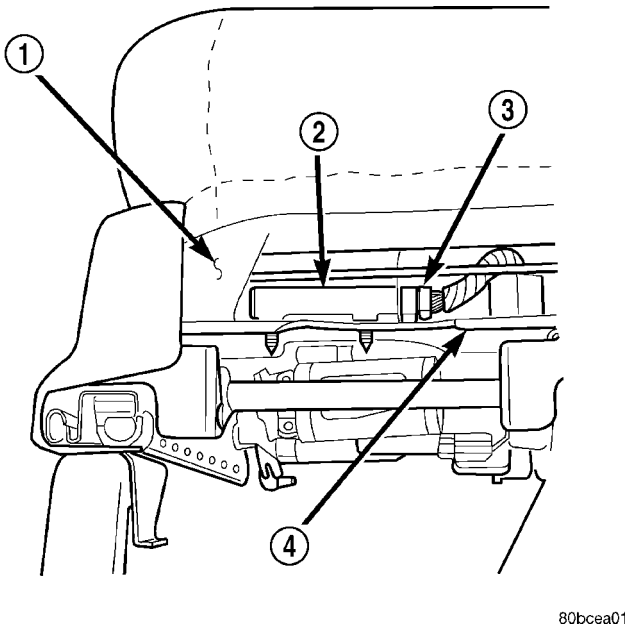

Fig. 10 Heated Seat Module Location- Typical

1 - SEAT CUSHION FRAME
2 - HEATED SEAT MODULE
3 - WIRE HARNESS CONNECTOR
4 - POWER SEAT TRACK FRONT BRACKET

INSTALLATION

(1) If the two plastic push-in fasteners for the heated seat module were damaged during removal, install new fasteners onto the heated seat module.

(2) Reconnect the power seat wire harness connector to the heated seat module connector receptacle. Be certain that the cavities in the power seat wire harness connector are aligned with the terminals in the heated seat module connector receptacle before pushing the connector firmly into place.

(3) Install the heated seat module on the power seat cushion pan.

(4) Reconnect the battery negative cable.

HORN SYSTEM

DESCRIPTION

A single note (domestic) or dual note (export) electric horn system is installed on this vehicle.

The horn system features electromagnetic horn(s). The horn system includes the following major components:

- **Horn** - The horn(s) are located on the right side frame rail.
- **Horn Relay** - The horn relay is located in the Junction Block (JB).
- **Horn Switch** - The horn switch is molded into the driver airbag.

OPERATION

The horn system operates on battery current received through a fuse in the Power Distribution Center (PDC). The horn system circuit is designed so that the system will remain operational, regardless of the ignition switch position.

DIAGNOSIS AND TESTING - HORN SYSTEM

HORN SYSTEM TEST TABLE

CONDITION	POSSIBLE CAUSE	CORRECTION
HORN SOUNDS CONTINUOUSLY. NOTE: IMMEDIATELY UNPLUG HORN AND RELAY IN THE JUNCTION BLOCK	1. INOPERATIVE HORN RELAY.	1. REPLACE RELAY, IF INOPERATIVE
	2. HORN CONTROL CIRCUIT TO RELAY SHORTED TO GROUND.	2. CHECK TERMINAL 65 IN PDC FOR CONTINUITY TO GROUND INDICATES: A. WIRING HARNESS SHORTED TO GROUND. B. FIND THE SHORT AND REPAIR AS NECESSARY.
	4. PINCHED HORN SWITCH WIRE UNDER DRIVER AIRBAG MODULE.	4. REPLACE DRIVER AIRBAG.
	5. INOPERATIVE HORN SWITCH	5. REPLACE DRIVER AIRBAG.

HORN SYSTEM (Continued)

CONDITION	POSSIBLE CAUSE	CORRECTION
HORN SOUND INTERMITTENTLY AS THE STEERING WHEEL IS TURNED.	1. HORN RELAY CONTROL CIRCUIT X3 IS SHORTED TO GROUND INSIDE STEERING WHEEL.	1. REMOVE DRIVER AIRBAG AND CHECK FOR RUBBING OR LOOSE WIRE/CONNECTOR, REPAIR AS NECESSARY.
	2. PINCHED HORN SWITCH WIRE UNDER DRIVER AIRBAG.	2. REPLACE DRIVER AIRBAG.
	3. INOPERATIVE HORN SWITCH.	3. REPLACE DRIVER AIRBAG.
HORN DOES NOT SOUND	1. CHECK FUSE 23 IN THE PDC.	1. REPLACE FUSE IF INOPERATIVE.
	2. NO VOLTAGE AT HORN RELAY TERMINALS 62 & 66 AND FUSE IS OK.	2. NO VOLTAGE, REPAIR PDC AS NECESSARY.
	3. OPEN CIRCUIT FROM TERMINAL 65 OF THE RELAY TO HORN SWITCH X3 CIRCUIT.	3. REPAIR CIRCUIT AS NECESSARY.
	4. INOPERATIVE OR DAMAGED HORN.	4. VOLTAGE AT HORN WHEN HORN SWITCH IS PRESSED, REPLACE HORN.
	5. INOPERATIVE HORN SWITCH	5. REPLACE DRIVER AIRBAG.
FUSE BLOWS WHEN HORN IS BLOWN	1. SHORT CIRCUIT IN HORN OR HORN WIRING	1. REMOVE HORN RELAY, CHECK FOR SHORTED HORN OR HORN WIRING. DISCONNECT HORN WIRE HARNESS TO ISOLATE SHORT AND REPAIR AS NECESSARY.
FUSE BLOWS WITHOUT BLOWING HORN NOTE: FOR WIRING REPAIRS REFER TO GROUP 8W, WIRE DIAGRAMS.	1. SHORT CIRCUIT	1. REMOVE RELAY, INSTALL NEW FUSE, IF FUSE DOES NOT BLOW REPLACE HORN RELAY. IF FUSE BLOWS WITH RELAY REMOVED, CHECK FOR SHORT TO GROUND WITH OHMMETER BETWEEN TERMINALS 62 & 66 AND THE FUSE TERMINAL. REPAIR AS NECESSARY.

HORN

DIAGNOSIS AND TESTING - HORN

(1) Disconnect wire connector at horn.

(2) Using a voltmeter, connect one lead to ground terminal and the other lead to the positive wire terminal.

(3) Depress the horn switch, battery voltage should be present.

(4) If no voltage,(Refer to 8 - ELECTRICAL/HORN - DIAGNOSIS AND TESTING). If voltage is OK, go to Step 5.

(5) Using ohmmeter, test ground wire for continuity to ground.

(6) If no ground repair as necessary.

(7) If wires test OK and horn does not sound, replace horn.

HORN (Continued)

REMOVAL

(1) Disconnect and isolate the battery negative cable.

(2) Remove the right front wheelhouse splash shield.

(3) Disconnect the harness connector.

(4) Remove the fastener securing the horn assembly to the vehicle (Fig. 1).

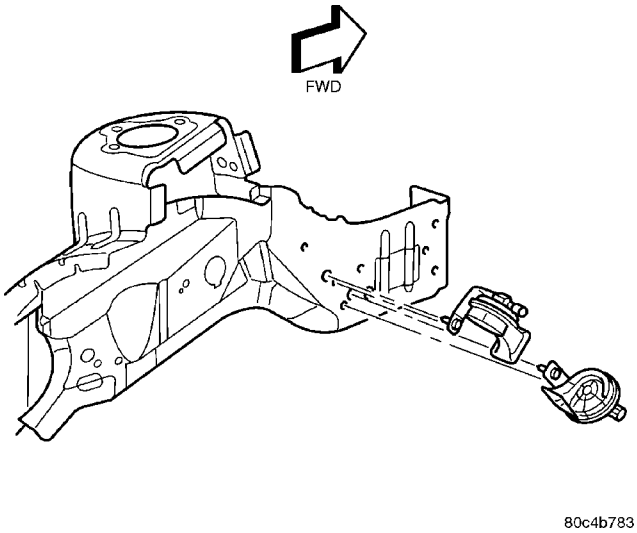

Fig. 1 HORN MOUNTING (EXPORT SHOWN)

INSTALLATION

(1) Install the fastener securing the horn assembly to the vehicle.

(2) Connect the harness connector.

(3) Install the right front wheelhouse splash shield.

(4) Connect the battery negative cable.

HORN RELAY

REMOVAL

(1) Disconnect and isolate the battery negative cable.

(2) Remove cover from Power Distribution Center (PDC).

(3) Using special tool C-4817, grip the relay by the sides and pull upward with an even effort (Fig. 2).

INSTALLATION

(1) Align relay with Power Distribution Center (PDC) and press into position.

(2) Install cover to PDC.

(3) Connect battery negative cable.

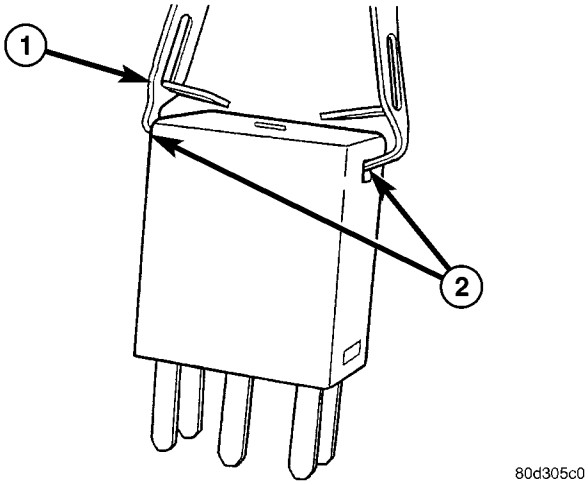

Fig. 2 RELAY REMOVAL

1 - SPECIAL TOOL C-4817
2 - RELAY

HORN SWITCH

DESCRIPTION

WARNING:
ON VEHICLES EQUIPPED WITH AN AIRBAG, REFER TO RESTRAINT SYSTEMS FOR WARNINGS AND CAUTIONS BEFORE SERVICING THE HORN SWITCH.

The horn switch is mounted inside the driver airbag. The horn switch is serviced with the driver airbag (Refer to 8 - ELECTRICAL/RESTRAINTS/ DRIVER AIRBAG - REMOVAL).

OPERATION

When the Driver Airbag Cover is pressed, the horn switch makes contact to ground. The ground signal is carried to the horn relay and the horn sounds. The horn switch grounds to the airbag housing.

REMOVAL

WARNING:
ON VEHICLES EQUIPPED WITH AN AIRBAG, REFER TO RESTRAINT SYSTEMS FOR WARNINGS AND CAUTIONS BEFORE SERVICING THE HORN SWITCH.

The horn switch is serviced with the driver airbag (Refer to 8 - ELECTRICAL/RESTRAINTS/DRIVER AIRBAG - REMOVAL).

IGNITION CONTROL

DESCRIPTION - IGNITION SYSTEM

NOTE: All engines use a fixed ignition timing system. Basic ignition timing is not adjustable. All spark advance is determined by the Powertrain Control Module (PCM).

The ignition system used on these engines is referred to as the Direct Ignition System (DIS). The system's four main components are the coils, crankshaft position sensor, spark plugs, and camshaft position sensor. If equipped with the coil on plug ignition system it utilizes an ignition coil for every cylinder and is mounted directly over the each spark plug.

OPERATION - IGNITION SYSTEM

The crankshaft position sensor and camshaft position sensor are hall effect devices. The camshaft position sensor and crankshaft position sensor generate pulses that are inputs to the PCM. The PCM determines engine position from these sensors. The PCM calculates injector sequence and ignition timing from crankshaft & camshaft position. For a description of both sensors, refer to Camshaft Position Sensor and Crankshaft Position Sensor.

PROTECTIVE SLEEVE

AUTO SHUT DOWN RELAY

DESCRIPTION

The relay is located in the Power Distribution Center (PDC). For the location of the relay within the PDC, refer to the PDC cover for location. Check electrical terminals for corrosion and repair as necessary

OPERATION

The engine switched battery (NGC vehicles) informs the PCM when the ASD relay energizes. A 12 volt signal at this input indicates to the PCM that the ASD has been activated. This input is also used to power certain drivers on NGC vehicles.

When energized, the ASD relay on NGC vehicles provides power to operate the injectors, ignition coil, generator field, O2 sensor heaters (both upstream and downstream), evaporative purge solenoid, EGR solenoid (if equipped) wastegate solenoid (if equipped), and NVLD solenoid (if equipped).

The ASD relay also provides a sense circuit to the PCM for diagnostic purposes. If the PCM does not receive 12 volts from this input after grounding the control side of the ASD relay, it sets a Diagnostic Trouble Code (DTC). The PCM energizes the ASD any time there is an engine speed that exceeds a predetermined value (typically about 50 rpm). The ASD relay can also be energized after the engine has been turned off to perform an O2 sensor heater test, if vehicle is equipped with OBD II diagnostics.

As mentioned earlier, the PCM energizes the ASD relay during an O2 sensor heater test. On NGC vehicles it checks the O2 heater upon vehicle start. The PCM still operates internally to perform several checks, including monitoring the O2 sensor heaters.

CAMSHAFT POSITION SENSOR

DESCRIPTION

On 2.0/2.4L engines the camshaft position sensor is mounted to the rear of the cylinder head (Fig. 1), (Fig. 2),.

OPERATION

The PCM sends approximately 5 volts to the Hall-effect sensor. This voltage is required to operate the Hall-effect chip and the electronics inside the sensor. The input to the PCM occurs on a 5 volt output reference circuit. A ground for the sensor is provided through the sensor return circuit. The PCM identifies camshaft position by registering the change from 5 to 0 volts, as signaled from the Camshaft Position sensor (Fig. 3).

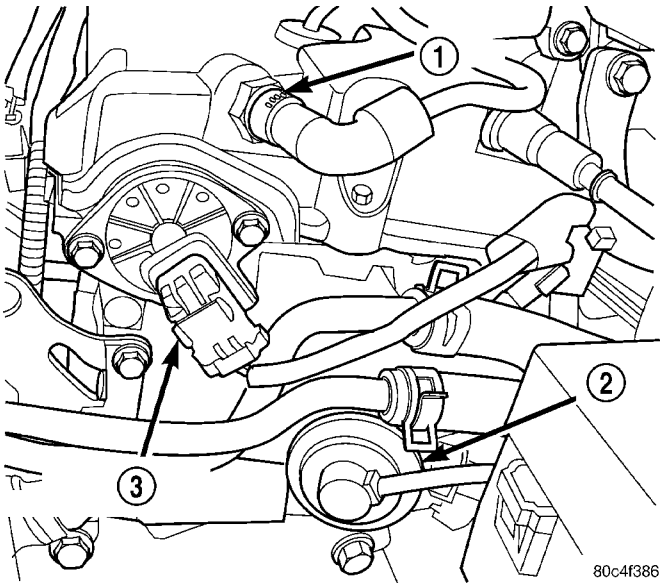

Fig. 1 Camshaft Position Sensor -2.0/2.4L DOHC

1 - PCV VALVE
2 - EGR VALVE
3 - CAMSHAFT POSITION SENSOR

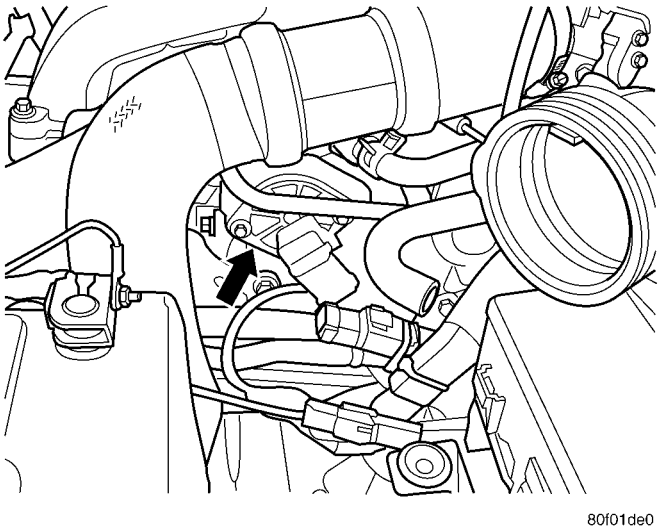

Fig. 2 CAMSHAFT POSITION SENSOR - 2.4L TURBO

On 2.0/2.4L engines a target magnet attaches to the rear of the camshaft and indexes to the correct position. The target magnet has fourteen different poles arranged in an asymmetrical pattern. As the target magnet rotates, the camshaft position sensor senses the change in polarity (Fig. 4).

The PCM determines fuel injection synchronization and cylinder identification from inputs provided by the camshaft position sensor (Fig. 1) and crankshaft position sensor. From the two inputs, the PCM determines crankshaft position.

CAMSHAFT POSITION SENSOR (Continued)

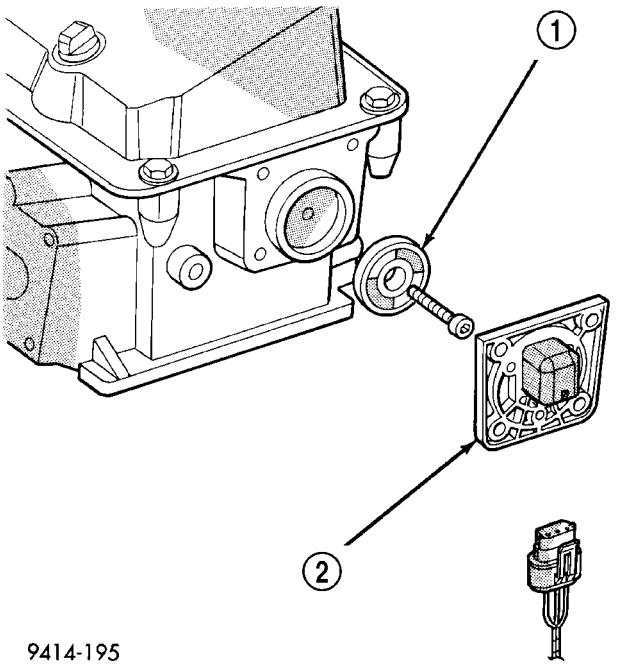

Fig. 3 Target Magnet - Typical

1 - CAM MAGNET/TARGET
2 - CAMSHAFT POSITION SENSOR

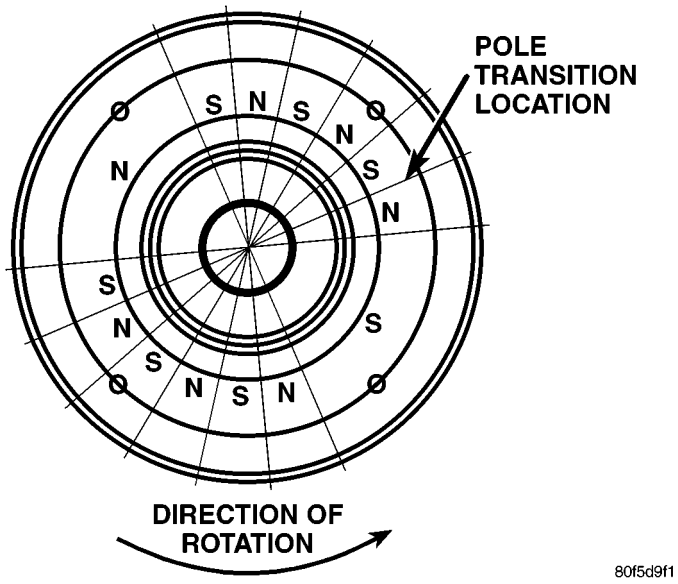

Fig. 4 Target Magnet Polarity - NGC

1 - TARGET MAGNET

The sensor input switches from high (5 volts) to low (0.30 volts) as the target magnet rotates. When the north pole of the target magnet passes under the sensor, the output switches high. The sensor output switches low when the south pole of the target magnet passes underneath.

REMOVAL

REMOVAL - 2.0/2.4L

(1) Remove the air cleaner lid, disconnect the inlet air temperature sensor and makeup air hose.

(2) Remove the negative battery cable.

(3) Disconnect electrical connector from camshaft position sensor.

(4) Remove camshaft position sensor mounting screws. Remove sensor.

(5) Loosen screw attaching target magnet to rear of camshaft (Fig. 5).

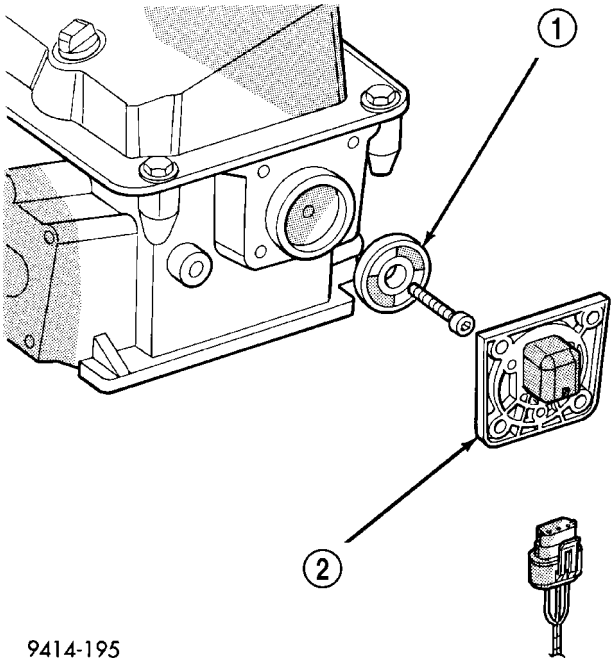

Fig. 5 Target Magnet Removal/Installation

1 - CAM MAGNET/TARGET
2 - CAMSHAFT POSITION SENSOR

REMOVAL - 1.6L

(1) Disconnect the negative battery cable.

(2) Relocate the power steering return hose.

(3) Disconnect the electrical connector from the camshaft sensor.

(4) Remove 1 screws from sensor.

(5) Remove sensor (Fig. 6).

CAMSHAFT POSITION SENSOR (Continued)

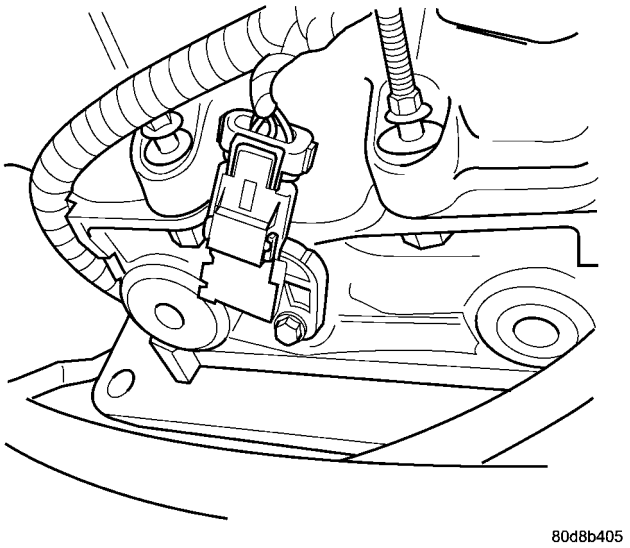

Fig. 6 CAMSHAFT SENSOR LOCATION

INSTALLATION

INSTALLATION - 2.0/2.4L

The target magnet has locating dowels that fit into machined locating holes in the end of the camshaft (Fig. 7).

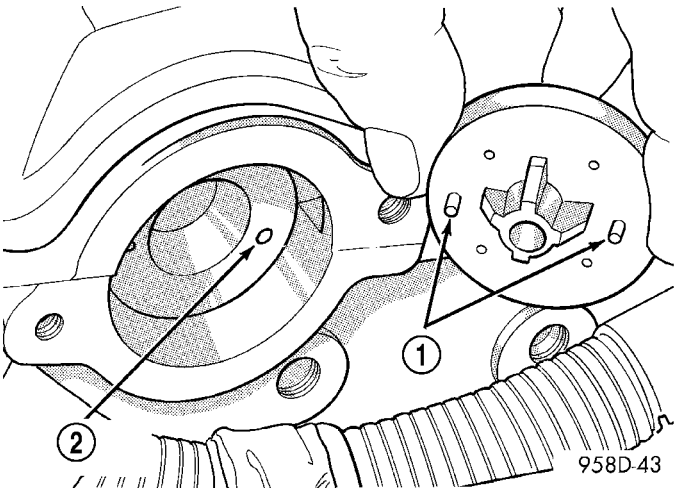

Fig. 7 Target Magnet Installation

1 - LOCATING DOWELS
2 - LOCATING HOLES (2)

(1) Install target magnet in end of camshaft. Tighten mounting screw to 3.6 N·m (32 ±5 in. lbs.) torque. Over torquing could cause cracks in magnet. If magnet cracks replace it.

(2) Install camshaft position sensor. Tighten sensor mounting screws to 9 N·m (80 ±15 in. lbs.) torque.

(3) Carefully attach electrical connector to camshaft position sensor. Installation at an angle may damage the sensor pins.

(4) Install the negative battery cable.

(5) Install the air cleaner lid, connect the inlet air temperature sensor and makeup air hose.

INSTALLATION - 1.6L

(1) Install sensor to cylinder head (Fig. 6).
(2) Tighten screws to 9 N·m (80 in. lbs.).
(3) Connect the electrical connector to the sensor.
(4) Relocate the power steering return line.
(5) Connect the negative battery cable

IGNITION COIL

DESCRIPTION

WARNING: THE DIRECT IGNITION SYSTEM GENERATES APPROXIMATELY 40,000 VOLTS. PERSONAL INJURY COULD RESULT FROM CONTACT WITH THIS SYSTEM.

The coil pack consists of 2 coils molded together. The coil pack is mounted on the valve cover (Fig. 8) or (Fig. 9).

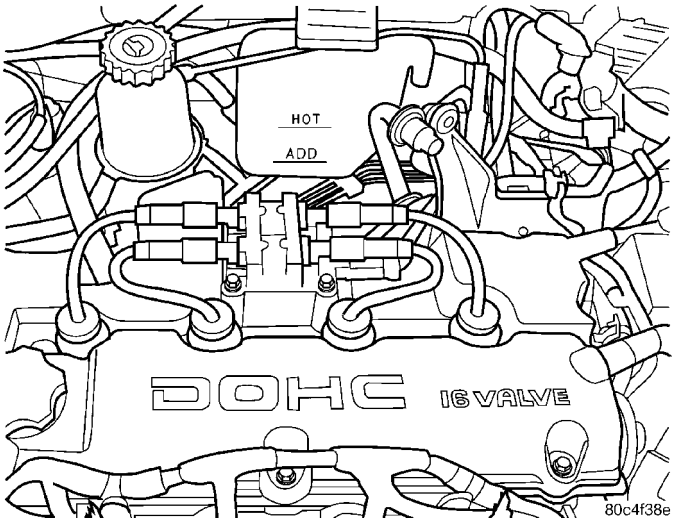

Fig. 8 Ignition Coil Pack—2.0/2.4L

OPERATION

WARNING: THE DIRECT IGNITION SYSTEM GENERATES APPROXIMATELY 40,000 VOLTS. PERSONAL INJURY COULD RESULT FROM CONTACT WITH THIS SYSTEM.

High tension leads route to each cylinder from the coil. The coil fires two spark plugs every power stroke. One plug is the cylinder under compression, the other cylinder fires on the exhaust stroke. Coil number one fires cylinders 1 and 4. Coil number two fires cylinders 2 and 3. The PCM determines which of the coils to charge and fire at the correct time.

IGNITION COIL (Continued)

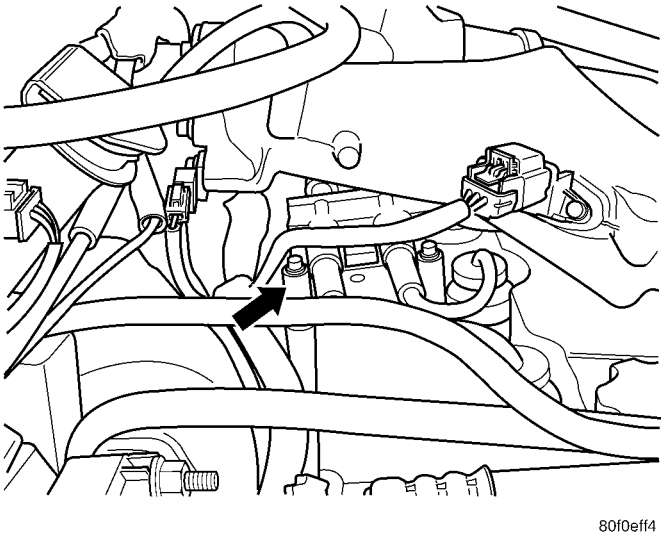

Fig. 9 IGNITION COIL LOCATION - 2.4L TURBO

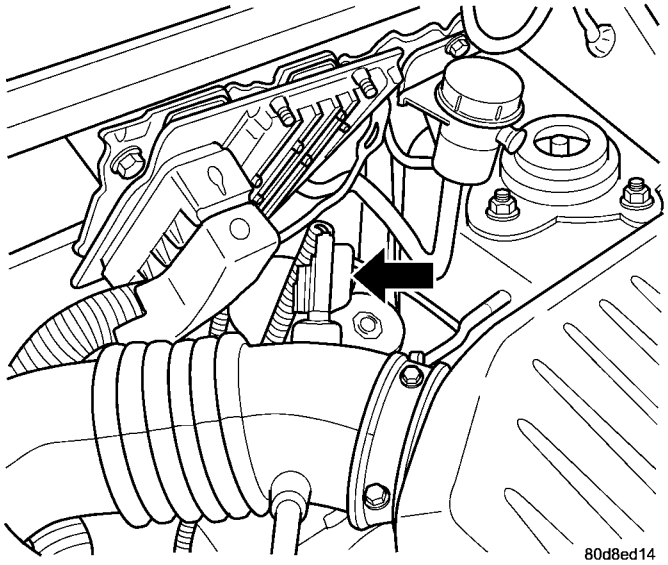

Fig. 10 INLET AIR TEMP. SENSOR

The Auto Shutdown (ASD) relay provides battery voltage to the ignition coil. The PCM provides a ground contact (circuit) for energizing the coil. When the PCM breaks the contact, the energy in the coil primary transfers to the secondary causing the spark. The PCM will de-energize the ASD relay if it does not receive the crankshaft position sensor and camshaft position sensor inputs.

REMOVAL

REMOVAL - 1.6L

NOTE: The 1.6L is attached with a rubber isolator system. Care must be exercised in retaining all the pieces and reinstalling in the order they where removed.

(1) Remove air cleaner assembly cover and disconnect the inlet air temperature sensor (Fig. 10).
(2) Disconnect the negative battery cable.
(3) Disconnect the electrical connector at the throttle body.
(4) Remove the purge hose from throttle body.
(5) Remove the 4 bolts from the upper to lower manifold (Fig. 11).

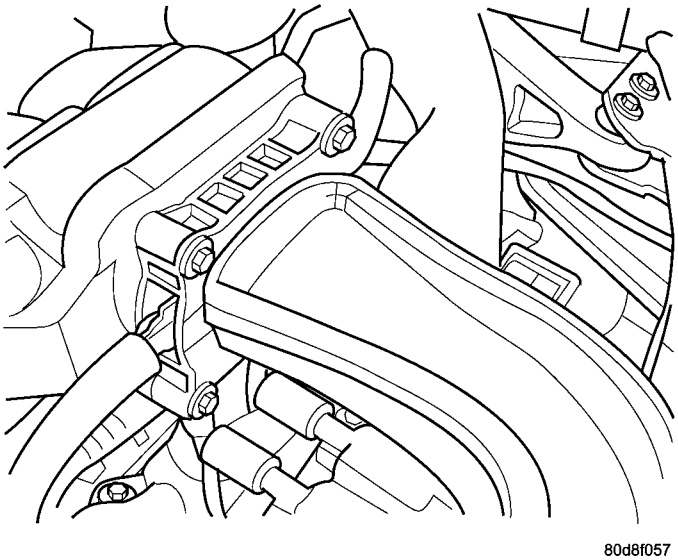

Fig. 11 UPPER MANIFOLD BOLTS

IGNITION COIL (Continued)

(6) Remove the 2 bolts to the upper manifold to struts (Fig. 12) and (Fig. 13).

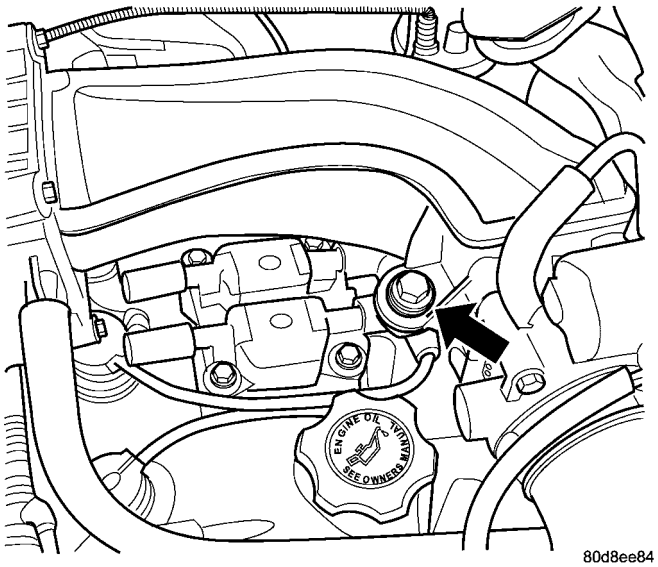

Fig. 12 FRONT STRUT BOLTS UPPER INTAKE

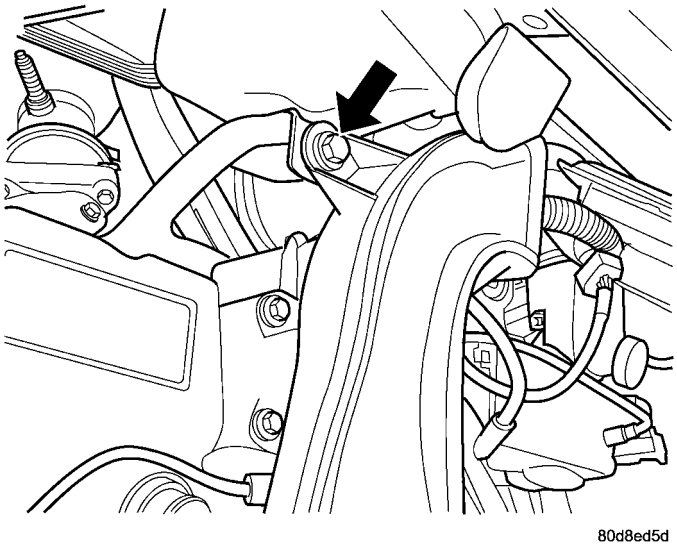

Fig. 13 REAR STRUT BOLTS UPPER INTAKE

(7) Remove the PCV hose and the brake booster hose from the upper manifold

(8) Remove the 4 bolts from the ignition coil (Fig. 14).

(9) Remove the spark plug cables from the ignition coil.

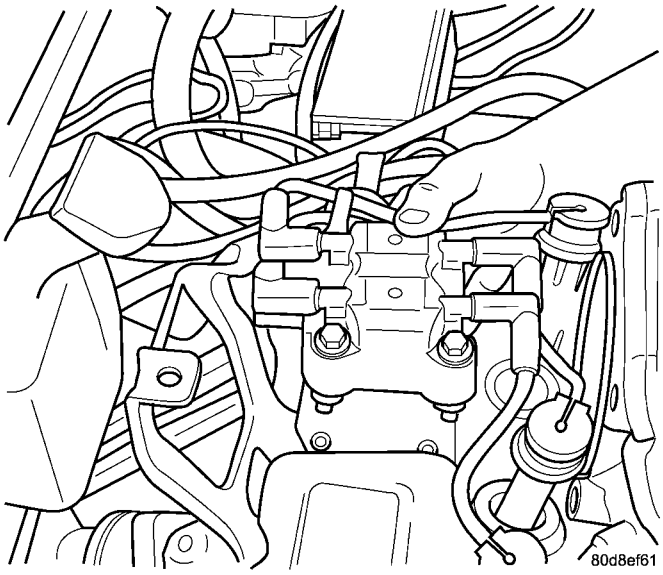

Fig. 14 IGNITION COIL

REMOVAL - 2.0/2.4L

The electronic ignition coil pack attaches directly to the valve cover (Fig. 15).

(1) Remove the negative battery cable.

(2) Disconnect electrical connector from coil pack.

(3) Remove coil pack mounting nuts.

(4) Remove coil pack.

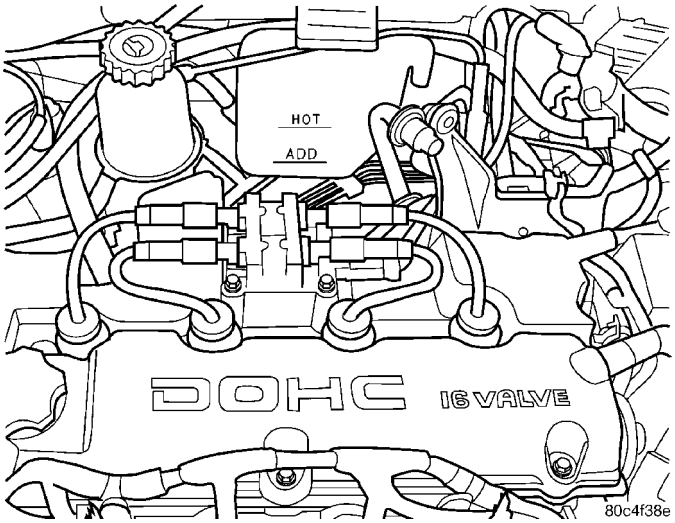

Fig. 15 Electronic Ignition Coil Pack—2.4L

IGNITION COIL (Continued)

REMOVAL - 2.4L TURBO

(1) Disconnect the negative battery cable.
(2) Remove the throttle control shield (Fig. 16).

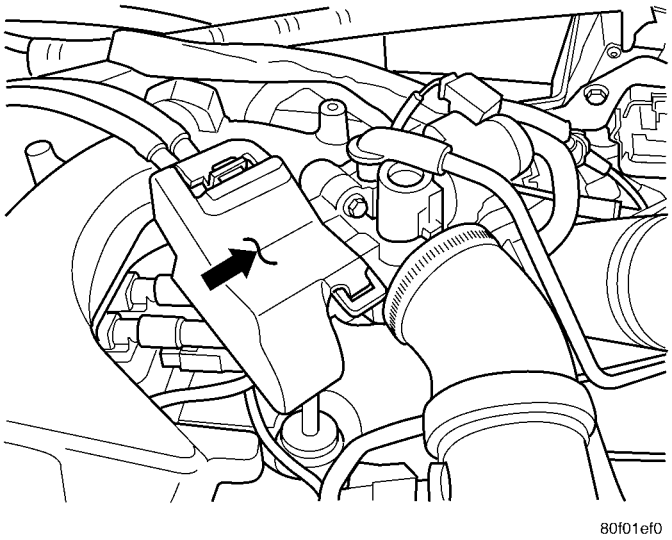

Fig. 16 THROTTLE CONTROL SHIELD

(3) Remove the throttle cables from the throttle body lever (Fig. 17).

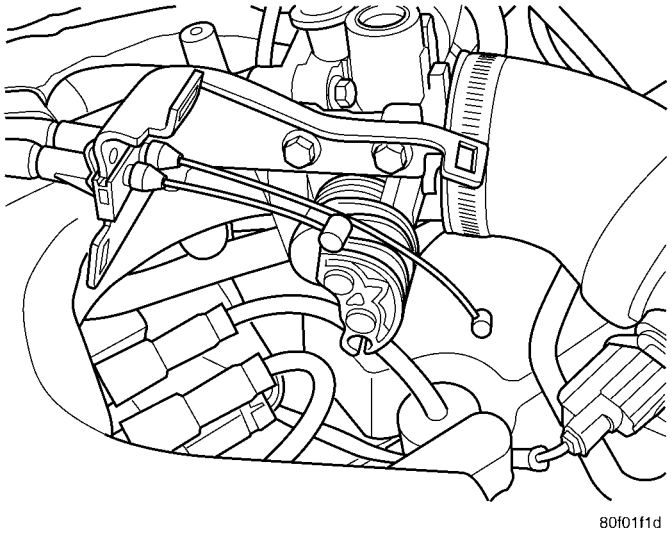

Fig. 17 THROTTLE CABLES

(4) Remove the throttle cable bracket and relocate (Fig. 18).

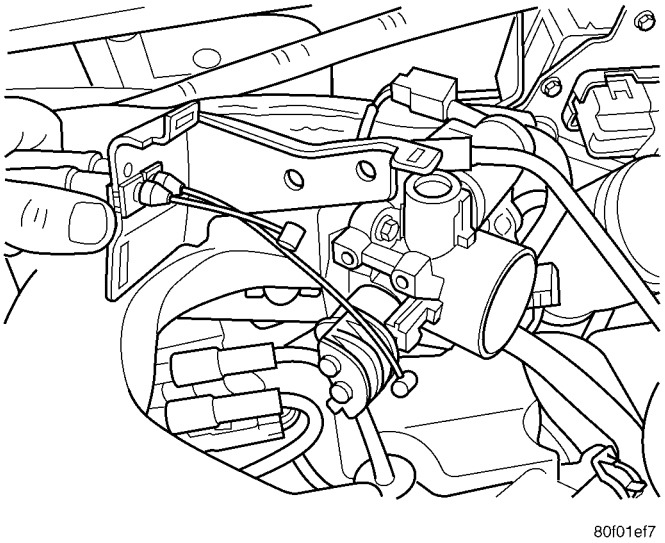

Fig. 18 THROTTLE CABLE BRACKET

(5) Remove the spark plug cables from the ignition coil.
(6) Unlock and disconnect the electrical connector from the ignition coil.
(7) Remove bolts from ignition coil. Twist coil to remove 2 of the bolts (Fig. 19) from the coil before removing it from vehicle.

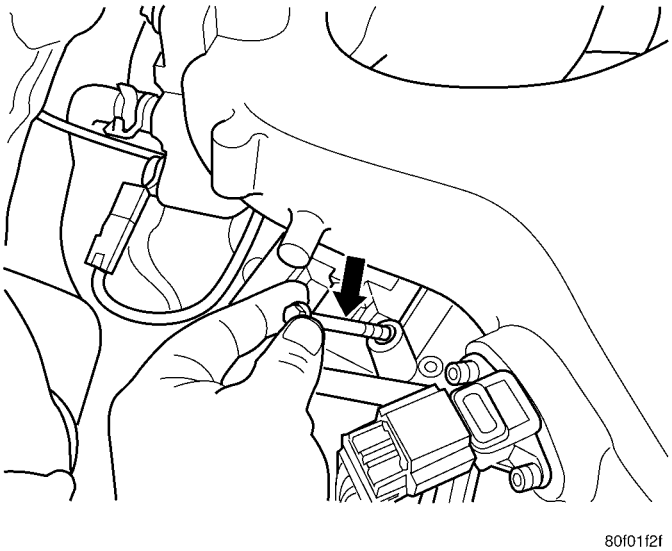

Fig. 19 IGNITION COIL BOLT

IGNITION COIL (Continued)

(8) Pull coil up (Fig. 20) and out by the throttle body side of the intake manifold (Fig. 21).

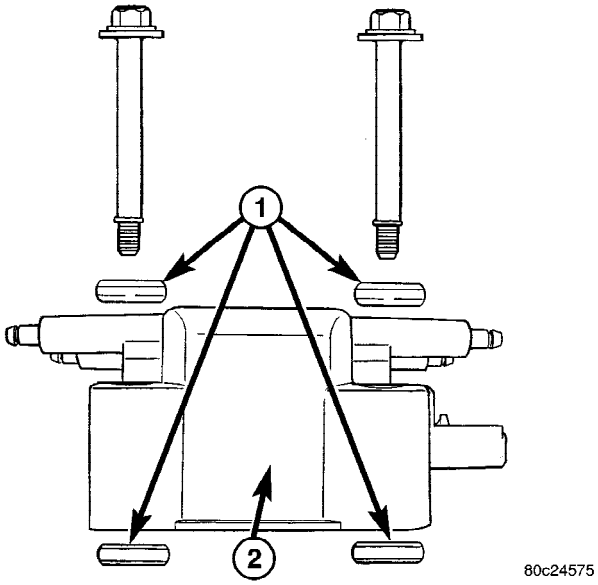

Fig. 22 RUBBER INSULATORS AND COIL

1 - Rubber Insulators
2 - Coil

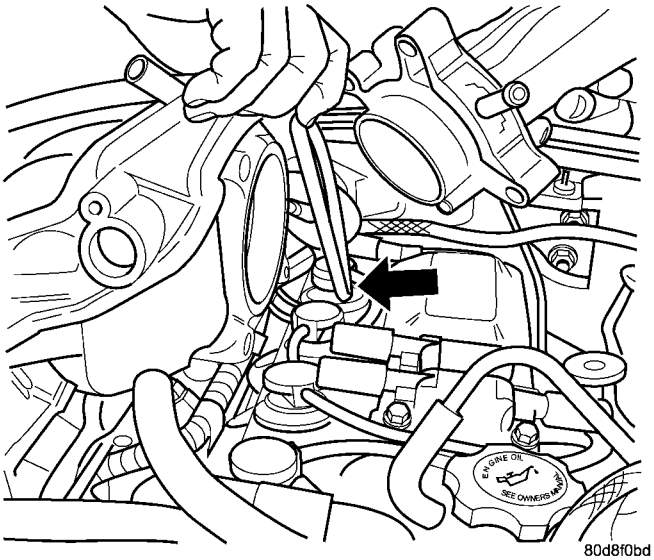

Fig. 23 UPPER INTAKE GASKET

INSTALLATION

INSTALLATION - 1.6L

(1) Install coil and insulators (Fig. 22).

(2) Tighten bolts to 12 N·m (105 ±20 in. lbs.).

(3) Install gasket to upper intake manifold (Fig. 23) and (Fig. 24).

(4) Install the 4 bolts from the upper to lower manifold (Fig. 11).

(5) Install the 2 bolts to the upper manifold to struts (Fig. 12) and (Fig. 13).

(6) Install the PCV hose and the brake booster hose to the upper manifold

(7) Install the purge hose to throttle body.

(8) Connect the electrical connector to throttle body.

(9) Connect the negative battery cable.

(10) Install air cleaner assembly cover and connect the inlet air temperature sensor (Fig. 10).

INSTALLATION- 2.0/2.4L

The electronic ignition coil pack attaches directly to the valve cover (Fig. 15).

(1) Install coil pack on valve cover. Tighten the bolts to 11.8 N·m (105 ±20 in. lbs.).

IGNITION COIL (Continued)

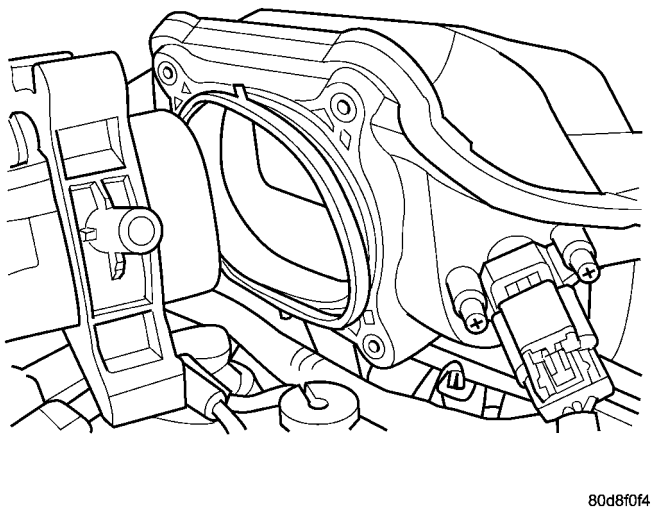

Fig. 24 UPPER INTAKE GASKET INPLACE

(2) Transfer spark plug cables to new coil pack. The coil pack towers are numbered with the cylinder identification. Be sure the ignition cables snap onto the towers.

(3) Install the negative battery cable.

INSTALLATION - 2.4L TURBO

(1) Install the coil on throttle body side of the intake manifold (Fig. 21), rotate down past the throttle body to the valve cover (Fig. 20).

(2) Connect and lock the electrical connector to the ignition coil.

(3) Install bolts to ignition coil. Twist coil to install 2 of the bolts (Fig. 19) to the coil after installing it to vehicle.

(4) Install the spark plug cables to the ignition coil.

(5) Install the throttle cable bracket (Fig. 18).

(6) Install the throttle cables to the throttle body lever (Fig. 17).

(7) Install the throttle control shield (Fig. 16).

(8) Connect the negative battery cable.

NOTE: Check and make sure that throttle body and attachments will not contact ignition cables.

IGNITION COIL CAPACITOR

REMOVAL - 2.4L TURBO

(1) Disconnect the negative battery cable.

(2) Remove the electrical connector from the ignition coil capacitor (Fig. 25).

(3) Remove mounting bolt and remove capacitor (Fig. 25).

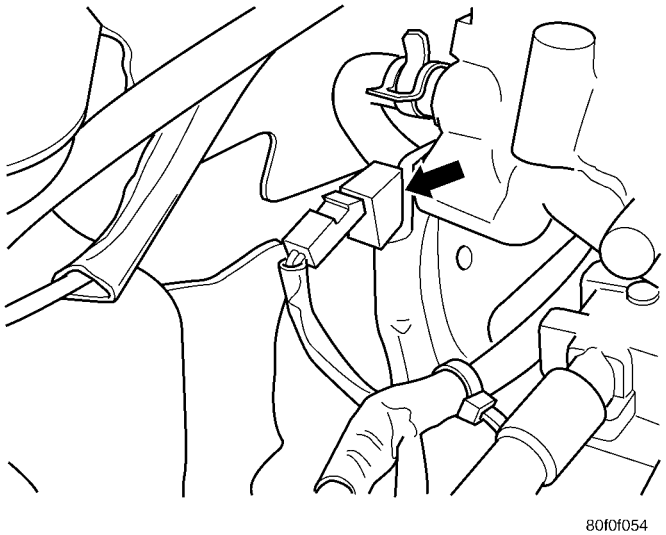

Fig. 25 COIL CAPACITOR - 2.4L TURBO

INSTALLATION - 2.4L TURBO

(1) Install coil capacitor and mounting bolt and tighten to 11.8 N·m (105 in. lbs.).

(2) Connect the electrical connector.

(3) Connect the negative battery cable.

KNOCK SENSOR

DESCRIPTION

The knock sensor is bolted to the cylinder block. The knock sensor is designed to detect engine vibration that is caused by detonation or preignition.

OPERATION

When the knock sensor detects a knock in one of the cylinders, it sends an input signal to the PCM. In response, the PCM retards ignition timing for all cylinders by a scheduled amount.

Knock sensors contain a piezoelectric material which constantly vibrates and sends an input voltage (signal) to the PCM while the engine operates. As the intensity of the crystal's vibration increases, the knock sensor output voltage also increases.

The voltage signal produced by the knock sensor increases with the amplitude of vibration. The PCM receives as an input the knock sensor voltage signal. If the signal rises above a predetermined level, the PCM will store that value in memory and retard ignition timing to reduce engine knock. If the knock sensor voltage exceeds a preset value, the PCM retards ignition timing for all cylinders. It is not a selective cylinder retard.

The PCM ignores knock sensor input during engine idle conditions. Once the engine speed exceeds a specified value, knock retard is allowed.

KNOCK SENSOR (Continued)

Knock retard uses its own short term and long term memory program.

Long term memory stores previous detonation information in its battery-backed RAM. The maximum authority that long term memory has over timing retard can be calibrated.

Short term memory is allowed to retard timing up to a preset amount under all operating conditions (as long as rpm is above the minimum rpm) except WOT. The PCM, using short term memory, can respond quickly to retard timing when engine knock is detected. Short term memory is lost any time the ignition key is turned off.

NOTE: Over or under tightening affects knock sensor performance, possibly causing improper spark control.

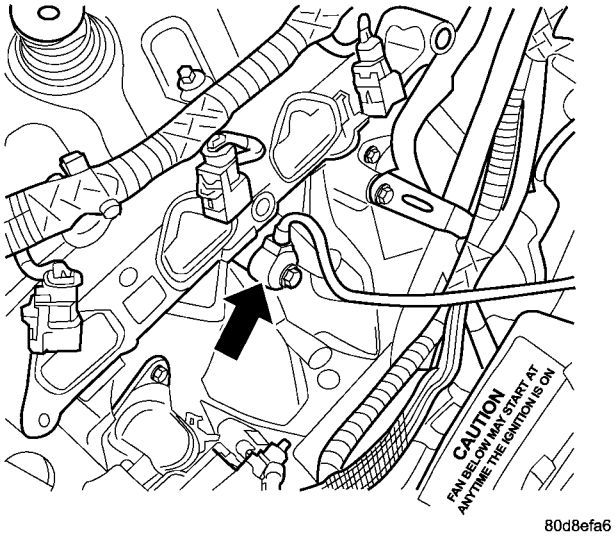

Fig. 27 KNOCK SENSOR

REMOVAL

REMOVAL - 1.6L

(1) Remove air cleaner assembly cover.

(2) Disconnect the negative battery cable.

(3) Disconnect the electrical connector for the sensor (Fig. 26) (Fig. 27).

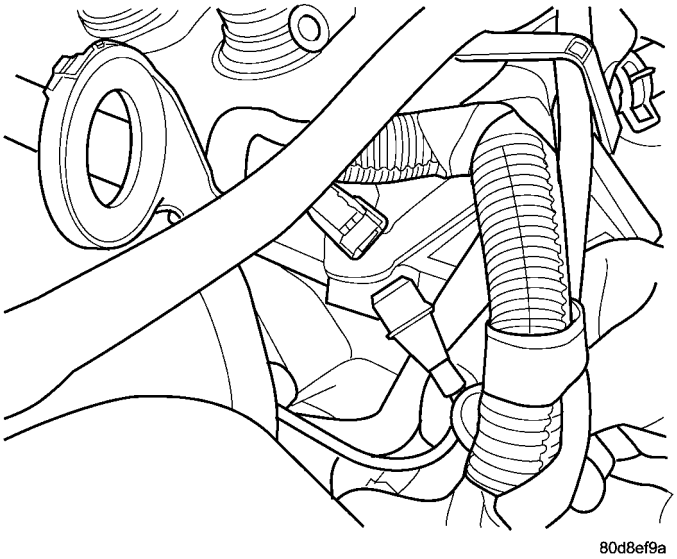

Fig. 26 WIRING CONNECTOR

(4) Remove knock sensor. The knock sensor is located under the intake manifold (Fig. 27).

REMOVAL - 2.0/2.4/2.4 TURBO/2.4L SRT-4

The knock sensor bolts into the side of the cylinder block in front of the starter under the intake manifold (Fig. 28).

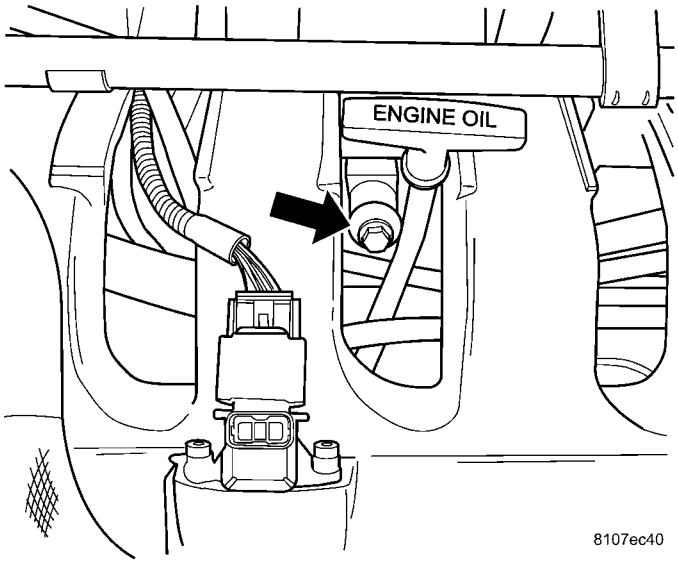

Fig. 28 KNOCK SENSOR LOCATION

KNOCK SENSOR (Continued)

(1) Disconnect the negative battery cable.
(2) Disconnect electrical connector from knock sensor (Fig. 29).

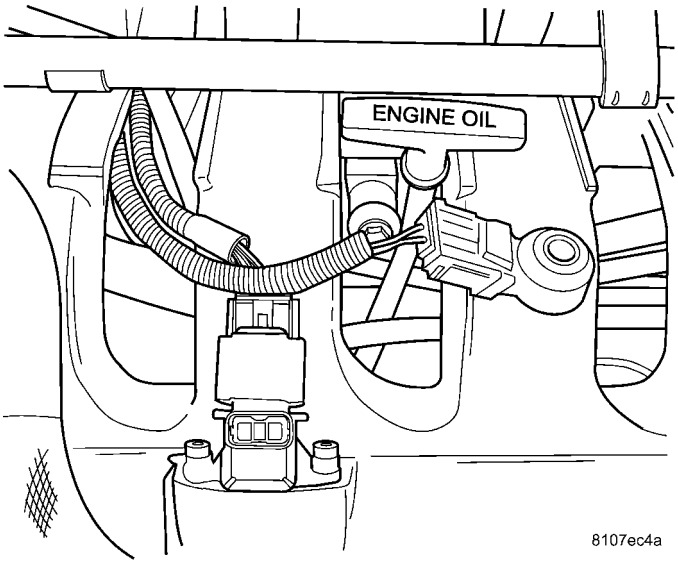

Fig. 29 KNOCK SENSOR REMOVED

(3) Remove the bolt holding the knock sensor
(4) Remove the knock sensor (Fig. 30).

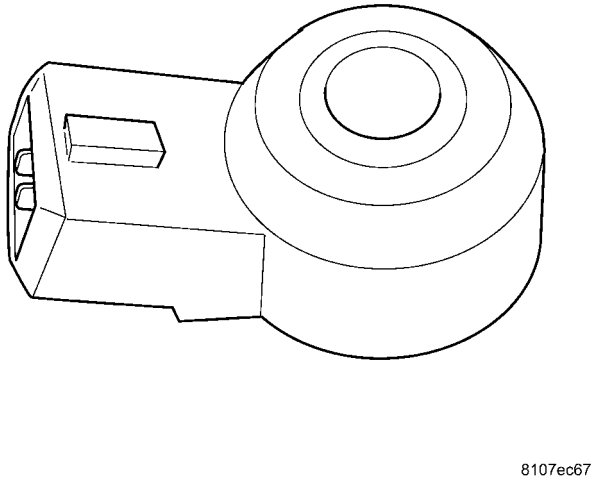

Fig. 30 KNOCK SENSOR

INSTALLATION

INSTALLATION - 1.6L

(1) Install the knock sensor (Fig. 27) Tighten knock sensor bolt to 22 N·m (195 in. lbs.) torque. **Over or under tightening effects knock sensor performance resulting in possible improper spark control.**.
(2) Connect the electrical connector for the sensor (Fig. 26).
(3) Connect the negative battery cable.
(4) Install air cleaner assembly cover.

INSTALLATION - 2.0/2.4/2.4 TURBO/2.4L SRT-4

The knock sensor bolts into the side of the cylinder block in front of the starter under the intake manifold.

(1) Install knock sensor (Fig. 30). Tighten knock sensor bolt to 22 N·m (195 in. lbs.) torque. **Over or under tightening effects knock sensor performance, possibly causing improper spark control.**
(2) Attach electrical connector to knock sensor (Fig. 29).
(3) Connect the negative battery cable.

SPARK PLUG

REMOVAL

REMOVAL - 1.6L

(1) Remove air cleaner assembly cover (Fig. 10).
(2) Disconnect the negative battery cable.
(3) Disconnect the electrical connector at the throttle body.
(4) Remove the purge hose from throttle body.
(5) Remove the 4 bolts from the upper to lower manifold (Fig. 11).
(6) Remove the 2 bolts to the upper manifold to struts (Fig. 12) and (Fig. 13).
(7) Remove the PCV hose and the brake booster hose from the upper manifold
(8) Remove the 4 bolts from the ignition coil.
(9) Remove the spark plug cables from the ignition coil.

SPARK PLUG (Continued)

Failure to route the cables properly could cause the radio to reproduce ignition noise, cross ignition of the spark plugs or short circuit the cables to ground.

REMOVE CABLES FROM COIL FIRST.

Always remove the spark plug cable by grasping the top of the spark plug insulator, turning the boot 1/2 turn and pulling straight up in a steady motion.

(10) Remove the spark plug using a quality socket with a rubber or foam insert and special tool # 8448 (Fig. 31) on the extension to keep from damaging the spark plug tubes in the cylinder head and valve cover.

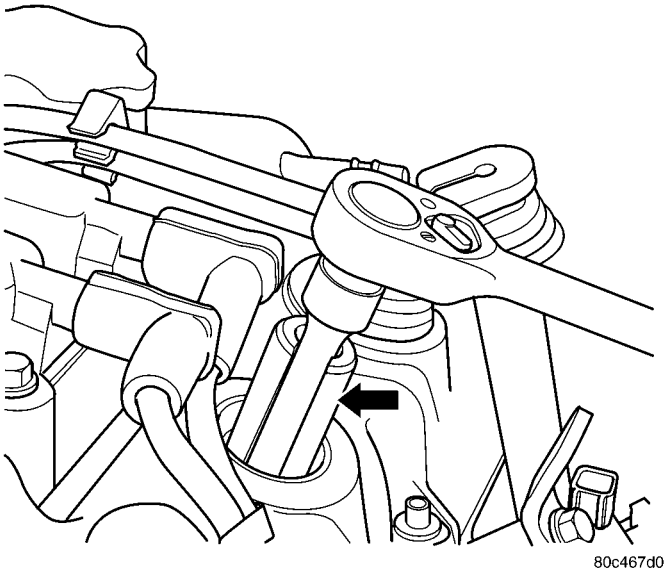

Fig. 31 SPECIAL TOOL # 8448

(11) Inspect the spark plug condition.

REMOVAL - 2.0/2.4L

Failure to route the cables properly could cause the radio to reproduce ignition noise, cross ignition of the spark plugs or short circuit the cables to ground.

NOTE: REMOVE cables from coil first before removing spark plug insulator.

Special care should be used when installing spark plugs in the 2.4L cylinder head spark plug wells. Be sure the plugs do not drop into the wells, damage to the electrodes can occur.

Always tighten spark plugs to the specified torque. Over tightening can cause distortion resulting in a change in the spark plug gap. Overtightening can also damage the cylinder head.

(1) Remove the air cleaner lid, disconnect the inlet air sensor and makeup air hose.

(2) Disconnect the negative battery cable.

(3) Remove the upper intake manifold, refer to the Engine section for more information.

(4) Disconnect the cable from the ignition coil first.

Always remove the spark plug cable by grasping the top of the spark plug insulator, rotate the boot 90° and pulling straight up in a steady motion.

(5) Remove the spark plug using a quality socket with a rubber or foam insert.

(6) Inspect the spark plug condition.

REMOVAL - 2.4L TURBO

Special care should be used when installing spark plugs in the 2.4L cylinder head spark plug wells. Be sure the plugs do not drop into the wells, damage to the electrodes can occur.

NOTE: REMOVE cables from the coil first before removing spark plug insulator.

(1) Disconnect the negative battery cable.

(2) Unlock and disconnect the MAP sensor electrical connector.

(3) Remove the throttle control shield.

(4) Disconnect the cable from the ignition coil first. Always remove the spark plug insulator, rotate the boot 90° and pulling straight up in a steady motion.

(5) Remove the spark plug using a quality socket with a rubber or foam insert (Fig. 32).

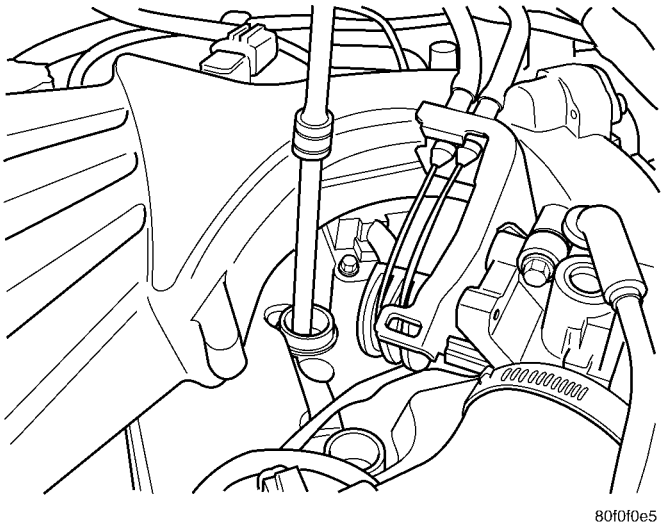

Fig. 32 SPARK PLUG REMOVAL/INSTALLATION - 2.4L TURBO

(6) Inspect the spark plug condition.

SPARK PLUG (Continued)

INSTALLATION

INSTALLATION - 1.6L

Failure to route the cables properly could cause the radio to reproduce ignition noise, cross ignition of the spark plugs or short circuit the cables to ground.

(1) To avoid cross threading, start the spark plug into the cylinder head by hand.

(2) Use special tool # 8448 to install and tighten the spark plug. Tighten spark plugs to 28 N·m (20 ft. lbs.) torque.

(3) Install spark plug insulators over spark plugs. Ensure the top of the spark plug insulator covers the upper end of the spark plug tube.

(4) Reconnect to cables to coil.

(5) Install the 4 bolts from the upper to lower manifold (Fig. 11).

(6) Install the 2 bolts to the upper manifold to struts (Fig. 12) and (Fig. 13).

(7) Install the PCV hose and the brake booster hose to the upper manifold

(8) Install the purge hose to throttle body.

(9) Connect the electrical connector to throttle body.

(10) Connect the negative battery cable.

(11) Install air cleaner assembly cover and inlet air temperature sensor (Fig. 10).

INSTALLATION - 2.0/2.4L

Failure to route the cables properly could cause the radio to reproduce ignition noise, cross ignition of the spark plugs or short circuit the cables to ground.

NOTE: REMOVE cables from coil first before removing spark plug insulator.

Special care should be used when installing spark plugs in the 2.4L cylinder head spark plug wells. Be sure the plugs do not drop into the wells, damage to the electrodes can occur.

Always tighten spark plugs to the specified torque. Over tightening can cause distortion resulting in a change in the spark plug gap. Overtightening can also damage the cylinder head.

(1) To avoid cross threading, start the spark plug into the cylinder head by hand.

WARNING: The tapered seat plugs for this application are torque-critical! It is imperative that 17.6 N·m +/- 2 (13 +/- 2 ft. lbs.) is NOT exceeded!

(2) Tighten spark plugs to 17.6 +/- 2 N·m (13 +/- 2 ft. lbs.) torque.

(3) Install spark plug insulators over spark plugs. Ensure the top of the spark plug insulator covers the upper end of the spark plug tube.

(4) Install spark plug cable to coil.

(5) Install the upper intake manifold, refer to the Engine section for more information

(6) Connect the negative battery cable.

(7) Install the air cleaner lid and connect the inlet air temperature sensor and makeup hose.

INSTALLATION - 2.4L TURBO

Special care should be used when installing spark plugs in the 2.4L cylinder head spark plug wells. Be sure the plugs do not drop into the wells, damage to the electrodes can occur.

NOTE: INSTALL cables to the spark plug first before installing them to the ignition coil.

(1) Install the spark plug using a quality socket with a rubber or foam insert. Tighten plus to N·m 17.6 ±2 (13 ±2 ft. lbs.). DO NOT OVER TIGHTEN, it is imperative that the torque is NOT EXCEEDED.

(2) Install the throttle control shield.

(3) Connect and lock the MAP sensor electrical connector.

(4) Connect the negative battery cable.

SPARK PLUG CABLE

DESCRIPTION

Spark Plug cables are sometimes referred to as secondary ignition wires. The wires transfer electrical current from the ignition coil pack to individual spark plugs at each cylinder. The resistive spark plug cables are of nonmetallic construction. The cables provide suppression of radio frequency emissions from the ignition system.

Check the spark plug cable connections for good contact at the coil, and spark plugs. Terminals should be fully seated. The insulators should be in good condition and should fit tightly on the coil, and spark plugs. Spark plug cables with insulators that are cracked or torn must be replaced.

Clean Spark Plug cables with a cloth moistened with a non-flammable solvent. Wipe the cables dry. Check for brittle or cracked insulation. The spark plug cables and spark plug boots are made from high temperature materials.

SPARK PLUG CABLE (Continued)

REMOVAL

REMOVAL - 1.6L

Failure to route the cables properly could cause the radio to reproduce ignition noise, cross ignition of the spark plugs or short circuit the cables to ground.

Remove spark plug cable from coil first.

Always remove the spark plug cable by grasping the top of the spark plug insulator, turning the boot 1/2 turn and pulling straight up in a steady motion.

REMOVAL - 2.0/2.4L

Failure to route the cables properly could cause the radio to reproduce ignition noise, cross ignition of the spark plugs or short circuit the cables to ground.

Remove spark plug cable from coil first.

Always remove the spark plug cable by grasping the top of the spark plug insulator, turning the boot 1/2 turn and pulling straight up in a steady motion.

INSTALLATION

INSTALLATION - 1.6L

Failure to route the cables properly could cause the radio to reproduce ignition noise, cross ignition of the spark plugs or short circuit the cables to ground. Install spark plug insulators over spark plugs. Ensure the top of the spark plug insulator covers the upper end of the spark plug tube, then connect the other end to coil pack.

INSTALLATION - 2.0/2.4L

Failure to route the cables properly could cause the radio to reproduce ignition noise, cross ignition of the spark plugs or short circuit the cables to ground. Install spark plug insulators over spark plugs. Ensure the top of the spark plug insulator covers the upper end of the spark plug tube, then connect the other end to coil pack.

INSTRUMENT CLUSTER

DESCRIPTION

The instrument cluster electronically drives the speedometer, odometer, fuel/temperature gauges, and tachometer. On the back of the cluster are two self-docking connectors, a 26-way and a 10-way.

All the indicators are located within the three gauges:

- Speedometer
- Tachometer
- Fuel/Temperature Gauge

This is a smart cluster and used to control many Body Control Module (BCM) functions.

The purpose of the instrument cluster gauges and indicator lamps is to keep the driver informed about the operating condition of the vehicle. If an abnormal condition occurs, the driver is informed by indicator lamp and a chime. The driver can seek service before damage occurs.

The instrument cluster has warning lamps and indicators for the following systems:

- Airbag
- Anti-lock Brakes (ABS) if equipped
- Brake Warning
- Charging System
- Electronic Throttle Control (ETC) (1.6L only)
- Engine Temperature
- Front Fog Lamps (if equipped)
- High Beam
- Liftgate Ajar
- Low Fuel
- Low Oil Pressure
- Malfunction Indicator Lamp (MIL) (Service Engine Soon)
- Rear Fog Lamps (Export)
- Seat Belt Warning
- Security System
- Trac-Off (if equipped)
- Wait To Start (Diesel Export Only)

The instrument cluster has a Vacuum Fluorescent (VF) display for the following systems:

- Cruise
- Door (ajar)
- Odometer
- Trac (if equipped)
- Trip
- PRNDL (Autostick Only)

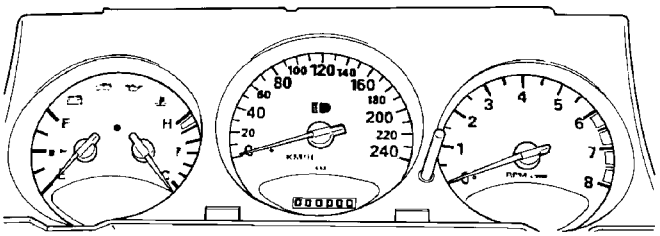
CHIME

The functions previously performed by the chime module are now part of the smart cluster. There is no serviceable part of the instrument cluster chime function. Replacement of the instrument cluster is necessary.

KEY IN IGNITION SWITCH

The Key-in switch is built into the ignition switch assembly. Should the Key-in switch require service, the ignition switch assembly must be replaced.

INSTRUMENT CLUSTER - EXPORT



80c41f77

Fig. 1 INSTRUMENT CLUSTER - EXPORT

INSTRUMENT CLUSTER (Continued)

The instrument cluster (Fig. 1) is referred to as an Electro-Mechanical Instrument Cluster (EMIC). Some of the features it controls are the gauges, courtesy lamps, chime control, Daytime Running Lamps (DRL) and cluster self diagnostics. The cluster sends and receives messages via the Programmable Communication Interface (PCI) data bus circuit (J1850). All instrument cluster indicators (Airbag, Seat belt, etc.) are LED's and are not replaceable, with the exception of the high beam indicator which is a bulb. The gauges are not serviced individually, thereby requiring complete replacement of the cluster if one indicator or gauge becomes defective.

OPERATION

The instrument cluster controls the courtesy lamps. It receives and sends messages to other modules via the PCI (J1850) bus circuit. It controls all the instrument illumination and the chime is also an integral part of the cluster.

All gauges are the analog type. When the ignition switch is moved to the OFF position, the cluster drives each gauge to its lowest position. The individual gauges are not serviceable and require complete replacement of the cluster if one or more gauges are inoperable.

The gauges are the magnetic air-core type. When the ignition switch is OFF, the gauge pointers should rest at or below the lowest graduation. The instrument cluster may be checked quickly by using the cluster self-diagnostics (Refer to 8 - ELECTRICAL/ INSTRUMENT CLUSTER - STANDARD PROCEDURE). After bulb check, (with the key in the RUN position and engine running) all MODULE warning indicators (if so equipped: Airbag, ABS, MIL, Charging System, ETC - Export only) should be extinguished. If any of these indicators stay ON, use the DRB III® scan tool to determine module faults. Also refer to the proper Body Diagnostic Procedures manual for cluster self-diagnostic results.

NOTE: If any of the gauge pointers are stuck on the wrong side of the pointer stop, perform one of the following:

- **Pull the M1 fuse in the fuseblock (refer to Wiring Diagrams for fuse locations) and key on. The gauge pointer will "sweep" the gauges and return all pointers to the correct side of the stop. Key OFF, reinsert the M1 fuse. The cluster will "sweep" the gauges one additional time. The cluster will "sweep" the gauges anytime there was a change in the state of the M1 fuse.**
- **Perform the instrument self-diagnostic check (Refer to 8 - ELECTRICAL/INSTRUMENT CLUSTER - STANDARD PROCEDURE). This will "sweep" all the pointers to the correct side of the pointer stop.**

One button is used to switch the display from trip to total mileage. Holding the button when the display is in the trip mode will reset the trip mileage. This button is also used to put the cluster in self-diagnostic mode (Refer to 8 - ELECTRICAL/INSTRUMENT CLUSTER - STANDARD PROCEDURE). Some of the indicators will come on briefly for a bulb check when the ignition is turned from OFF to ON. The LED's are non serviceable and if one or more warning indictor LED's are out, the entire cluster must be replaced.

In the event that the instrument cluster looses communication with all other modules on the PCI bus, the cluster will display "nobuS" in the VF display. The VF display also displays "Door", "Cruise", "Trac", and odometer trip or total.

If the cluster does not detect voltage on the M1 circuit, the message "FUSE" will alternate with the odometer/trip odometer. The lack of voltage can be due to the M1 Fused B(+) (IOD) fuse being open, or a circuit problem.

Indicator lamps use ON/OFF switch functions for operation, while gauges use a sending unit or sensor.

The instrument cluster will learn some features of the vehicle that it is installed in so swapping clusters from vehicle to vehicle is not recommended.

The features that are learned are:

- ABS
- Traction Control
- SKIM
- RKE
- Air Bags
- Cruise Control
- Lowest/Highest Fuel Level

INSTRUMENT CLUSTER - EXPORT

When the ignition key is ON, the instrument cluster indicator lamps will come on for a brief bulb check. The seat belt indicator lamp will remain ON until the (Driver) seat belt is fastened. The chime will sound for 6 seconds if the seat belt is unbuckled when the ignition is first turned ON. The export instrument cluster operates in the same manner as non-export clusters. Refer to the appropriate Body Diagnostic Procedures manual for complete diagnosis and testing of the instrument cluster.

INSTRUMENT CLUSTER (Continued)

DIAGNOSIS AND TESTING

DIAGNOSIS AND TESTING - INSTRUMENT CLUSTER WARNING/INDICATOR LAMPS

Every time the vehicle is switched to the START/RUN position, the cluster goes through a BULB CHECK. This tests most of the indicator lamps and Vacuum Fluorescent (VF) displays. If any of the lamps fail to light during the bulb check, refer to the proper Body Diagnostic Procedures manual. The lamps are not replaceable except for the high beam indicator and gauge illumination bulbs. None of these though will illuminate, along with the security indicator, during the bulb check at initial KEY ON.

To diagnose the cluster lamps first place the cluster in self-diagnostic mode. With the ignition switch in the OFF position, press the trip odometer reset button down. Simultaneously turn the ignition key to the ON position and release the trip reset button. Depending on optional equipment, the indicator lamps and VF displays should illuminate except for the fog lampm liftgate ajar, and any unlearned features.

DIAGNOSIS AND TESTING - MULTIPLE/INDIVIDUAL GAUGES INOPERATIVE

Test speedometer, tachometer and other gauges for malfunction using the following:

(1) First perform Cluster Self-Diagnostics (Refer to 8 - ELECTRICAL/INSTRUMENT CLUSTER - STANDARD PROCEDURE). If there is a response, watch for the effected gauge(s) for operation. Replace cluster as necessary. If there is no response to the cluster self-diagnostics, go to Step 2.

(2) Remove the cluster (Refer to 8 - ELECTRICAL/INSTRUMENT CLUSTER - REMOVAL).

(3) Check for ignition voltage at Pin 14 of the 26-way cluster wire harness connector. Refer to Wiring Diagrams for connector views. Check for battery voltage at Pin 4 of the 26-way connector. If no voltage, repair as necessary.

(4) Check Pin 1 and Pin 2 of the 26-way connector for continuity to ground. If no ground, repair as necessary.

(5) If the voltage and ground are OK, and the pins or the connectors are not distorted, replace the instrument cluster(Refer to 8 - ELECTRICAL/INSTRUMENT CLUSTER - REMOVAL).

(6) **Autostick clusters only** - In KEY UNLOCK/RUN/START there is B+ battery voltage at Pin 15 of the 26-way connector. Refer to Step 3.

INSTRUMENT CLUSTER (Continued)

STANDARD PROCEDURE - SELF-DIAGNOSTICS

To put the instrument cluster in Self-Diagnostic Mode, press the trip reset button down and then turn the ignition to the ON position simultaneously, then release the button. The gauges will increment to selected stops and all indicators will light with the exception of liftgate ajar and fog lamp indicators. The oil lamp will come on when the ignition is turned ON and the engine is OFF. Refer to the proper Body Diagnostic Procedures manual if one or more indicators don't light, or a gauge does not appear to be functioning correctly.

NOTE: If a vehicle/instrument cluster is received with the instrument cluster gauge pointers on the wrong side of the pointer stops, momentarily remove the M1 fuse, located in the Power Distribution Center (PDC) in the engine compartment, then replace. The gauge pointers should then step through the scales and then sweep back to the proper side of the pointer stops.

REMOVAL

CAUTION: DO NOT turn cluster upside down for longer than 30 minutes (preferably NEVER). This can result in dampening fluid within the gauge pointer assembly to leak causing permanent damage to the instrument cluster gauges.
DO NOT expose the instrument cluster to direct sunlight for extended periods of time. Any overexposure to direct sunlight permanently warps the internal mask of the instrument cluster, causing the pointers to stick. It is acceptable to store the instrument cluster on the floor of the vehicle, gauges facing up, out of direct sunlight.
DO NOT do an electrical "HOT SWAP" when replacing or testing clusters. Ensure that the ignition is OFF with the M1 fuse removed, or the battery negative cable is disconnected. Partial mating of the cluster connector circuits can damage and/or destroy the cluster microprocessor if power is available.
DO NOT swap clusters between vehicles. The instrument cluster has learned information stored in its microprocessor for Airbags, Anti-Lock Brakes, Traction Control, Cruise, and Smart Key Immobilizer. Swapping clusters between cars, may result in the improper illumination of cluster indicators associated with the above features.

(1) Open hood.
(2) Disconnect and isolate the battery negative cable.
(3) Remove the instrument cluster bezel. Refer to Body, Instrument Panel, Instrument Cluster Bezel, Removal.
(4) Remove four screws to the instrument cluster (Fig. 2) and pull straight back to release off of self-docking connectors (Fig. 3).

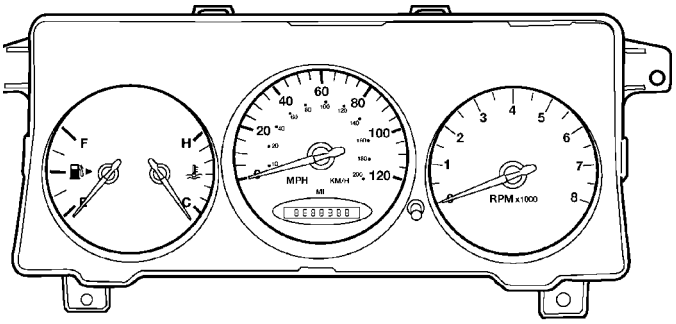

Fig. 2 INSTRUMENT CLUSTER

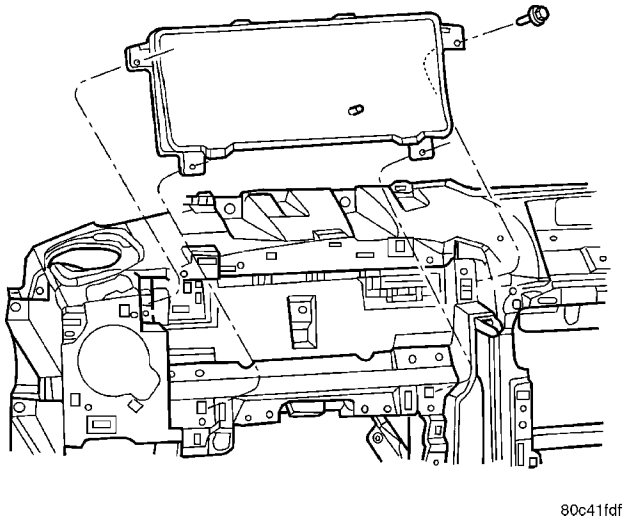

Fig. 3 INSTRUMENT CLUSTER REMOVE/INSTALL

INSTRUMENT CLUSTER (Continued)

INSTALLATION

CAUTION: DO NOT turn cluster upside down for longer than 30 minutes (preferably NEVER). This can result in dampening fluid within the gauge pointer assembly to leak causing permanent damage to the instrument cluster gauges.
DO NOT expose the instrument cluster to direct sunlight for extended periods of time. Any overexposure to direct sunlight permanently warps the internal mask of the instrument cluster, causing the pointers to stick. It is acceptable to store the instrument cluster on the floor of the vehicle, gauges facing up, out of direct sunlight.
DO NOT do an electrical "HOT SWAP" when replacing or testing clusters. Ensure that the ignition is OFF with the M1 fuse removed, or the battery negative cable is disconnected. Partial mating of the cluster connector circuits can damage and/or destroy the cluster microprocessor if power is available.
DO NOT swap clusters between vehicles. The instrument cluster has learned information stored in its microprocessor for Airbags, Anti-Lock Brakes, Traction Control, Cruise, and Smart Key Immobilizer. Swapping clusters between cars, may result in the improper illumination of cluster indicators associated with the above features.

(1) Align the cluster over the self-docking connectors and push firmly into place until seated.
(2) Install four screws to the instrument cluster (Fig. 2)and pull straight back to release off of self-docking connectors (Fig. 3).
(3) Install the instrument cluster bezel. Refer to Body, Instrument Panel, Instrument Cluster Bezel, Installation.
(4) Connect the battery negative cable.
(5) Close hood.
(6) Verify vehicle and system operation.

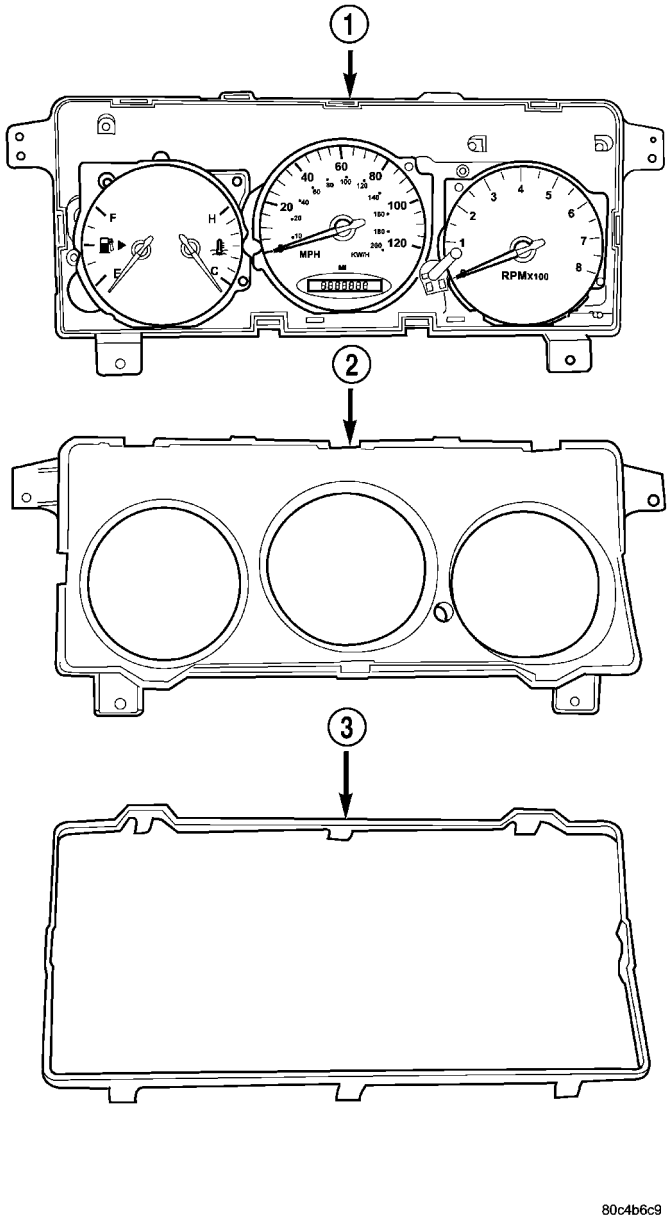

Fig. 4 INSTRUMENT CLUSTER BREAKDOWN

1 - CLUSTER
2 - MASK
3 - LENS

CLUSTER MASK/LENS

REMOVAL

(1) Remove instrument cluster (Refer to 8 - ELECTRICAL/INSTRUMENT CLUSTER - REMOVAL).
(2) To separate the mask/lens from the cluster housing, depress the locking tabs, starting at one point and working all the way around the cluster, and then pull up on the mask/lens (Fig. 4).

INSTALLATION

(1) To install new mask/lens, just place in position and snap together.
(2) Install instrument cluster (Refer to 8 - ELECTRICAL/INSTRUMENT CLUSTER - INSTALLATION).

BACK-UP LAMP UNIT (Continued)

(2) Remove back up lamp assembly.

(3) Remove the bulb socket from the lamp housing by rotating the socket counter-clockwise until the socket is free of the housing.

INSTALLATION

(1) Install the bulb socket into the lamp housing by rotating the socket clockwise until fully seated.

(2) Place back-up lamp assembly into position.

(3) Test lamp operation

(4) Install screws attaching back-up lamp unit to fascia.

BRAKE LAMP SWITCH

DESCRIPTION

The brake lamp switch is located under the instrument panel, at the brake pedal arm (Fig. 2). It has three internal switches controlling various functions of the vehicle. It's main function is to control operation of the vehicle's brake lamps. Other functions include speed control deactivation, brake sense for the antilock brake system and brake sense for the brake transmission shift interlock.

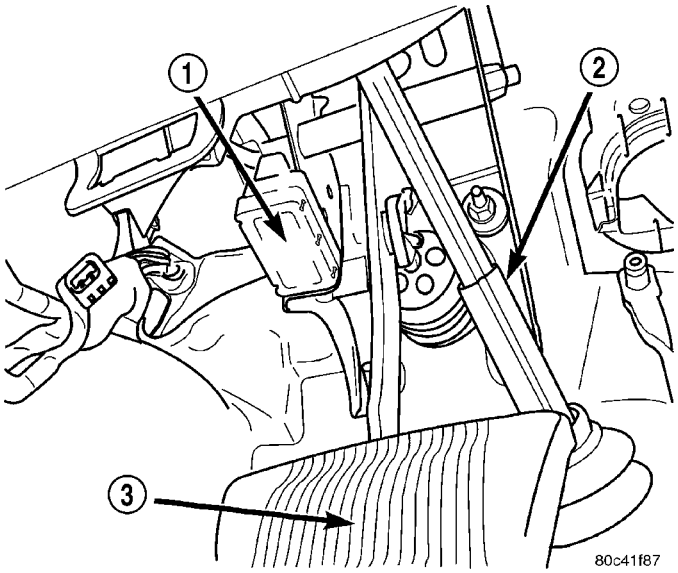

Fig. 2 BRAKE LAMP SWITCH

1 - BRAKE LAMP SWITCH
2 - STEERING COLUMN COUPLER
3 - BRAKE PEDAL

CAUTION: The switch can only be adjusted once. That is during initial installation of the switch. If the switch is not adjusted properly or has been removed for some service, a new switch must be installed and adjusted.

OPERATION

When the brake pedal is pressed, the plunger on the outside of the brake lamp switch extends outward. This action opens or closes the contacts of the three switches inside the brake lamp switch.

With the brake pedal pressed down (plunger extended), the switch for terminals 1 and 2 is closed completing the circuit. The switch for terminals 3 and 4 is open and so is the switch for 5 and 6.

When the brake pedal is released (plunger pushed in), the three switches assume the opposite positions. The switch for terminals 1 and 2 is now open while the other two switches are now closed, completing their circuits.

DIAGNOSIS AND TESTING - BRAKE LAMP SWITCH

NOTE: Before proceeding with this diagnostic test, verify the adjustment lever on the back of the switch is in the adjusted position. If the lever is in the non-adjusted (diagonal) position it may have never been adjusted. For adjustment, (Refer to 8 - ELECTRICAL/LAMPS/LIGHTING - EXTERIOR/BRAKE LAMP SWITCH - INSTALLATION).

If the electrical circuit has been tested and the brake lamp switch is suspected of being faulty, it can be tested using the following method.

(1) Remove the switch from the vehicle (Refer to 8 - ELECTRICAL/LAMPS/LIGHTING - EXTERIOR/BRAKE LAMP SWITCH - REMOVAL).

(2) With the switch in the released position (plunger extended), use an ohmmeter to test each of the three internal switches as shown (Fig. 3). You should achieve the results as listed in the figure.

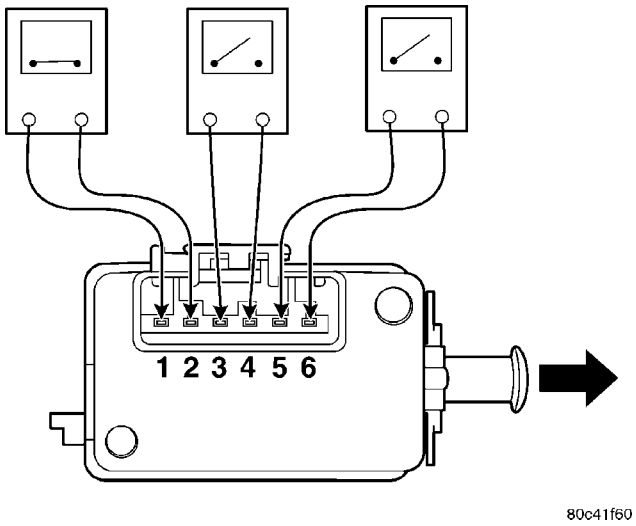

Fig. 3 SWITCH TEST - RELEASED POSITION

BRAKE LAMP SWITCH (Continued)

(3) Gently push the plunger on the brake lamp switch in until it stops.

(4) With the switch in this depressed position (plunger pushed in), use an ohmmeter to test each of the three internal switches as shown (Fig. 4). You should achieve the results as listed in the figure.

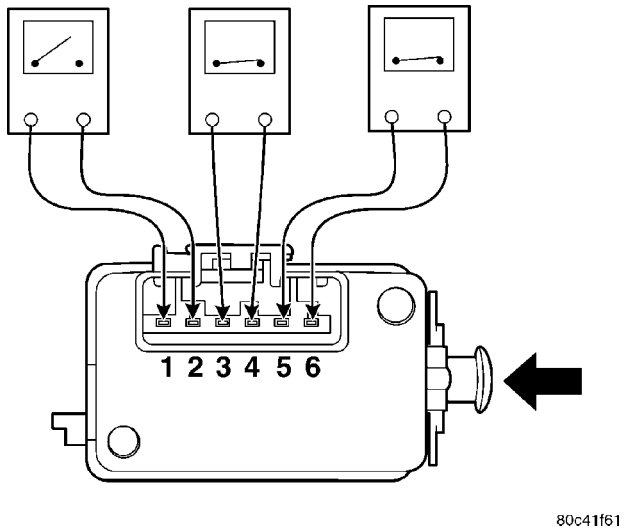

Fig. 4 SWITCH TEST - DEPRESSED POSITION

If you do not achieve the results as listed in both figures, the switch is faulty and must be replaced. Refer to Removal And Installation in this section.

If the switch is found to be operating properly, it may be misadjusted. Do not reinstall the switch, replace it (Refer to 8 - ELECTRICAL/LAMPS/LIGHTING - EXTERIOR/BRAKE LAMP SWITCH - INSTALLATION).

CAUTION: The switch can only be adjusted once. That is during initial installation of the switch. If the switch is not adjusted properly or has been removed for any reason, a new switch must be installed and adjusted.

REMOVAL

(1) Unclip the air cleaner cover (two clips) and move the cover aside.

(2) Disconnect and isolate the battery negative cable from its post on the battery.

(3) Remove the silencer pad below the knee blocker.

(4) Fold down and remove the knee blocker below the steering column.

(5) Remove the brake lamp switch from its bracket by rotating the switch in a counterclockwise direction approximately 30 degrees, then pulling the switch rearward.

(6) Disconnect the wiring harness connector.

(7) Discard the brake lamp switch. **It must not be reused.**

INSTALLATION

CAUTION: Do not reuse the original brake lamp switch. The switch can only be adjusted once. That is during initial installation of the switch. If the switch is not adjusted properly or has been removed for some service, a new switch must be installed and adjusted.

(1) Obtain NEW brake lamp switch. The adjustment lever on the new switch should be at a 45° angle from the wiring connector. **If the adjustment lever is parallel with the wiring connector, the switch has been pre-set and must be scrapped. DO NOT ATTEMPT TO RESET (OR RE-ADJUST) THE BRAKE LAMP SWITCH.**

(2) Connect the wiring harness to the connector on the switch.

(3) Mount and adjust the NEW brake lamp switch using the following steps:

(a) Install the switch in its bracket by aligning the index tab on the switch with the notch in the mounting bracket.

(b) When the switch body is fully seated in its bracket, rotate the switch clockwise approximately 30° to lock the switch into place.

(c) With the brake pedal in the fully released position, move the adjustment lever on the brake lamp switch from the 45° angled non-adjusted position, clockwise as shown, until it is parallel with the wiring connector (Fig. 5). The brake lamp switch is now properly adjusted to the vehicle.

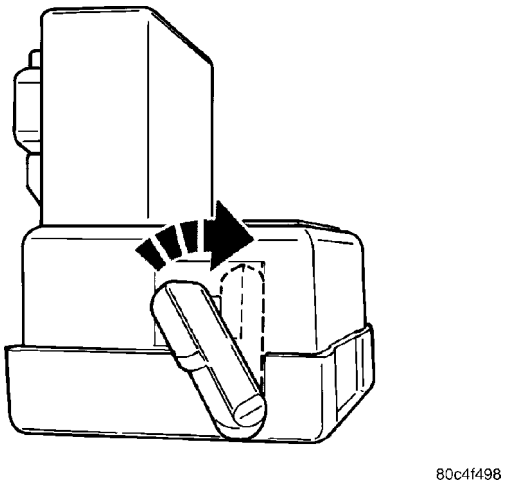

Fig. 5 Adjustment Lever Movement

(4) Install the knee blocker.

(5) Install the silencer pad below the knee blocker.

(6) Reconnect the battery negative terminal.

(7) Reinstall the air cleaner cover (two clips).

(8) Check the stop lamps to verify they are operating properly and not staying on when the pedal is in the released position.

BRAKE LAMP SWITCH (Continued)

(9) Road test the vehicle to ensure proper operation of the brakes (including ABS) and speed control (if equipped).

CENTER HIGH MOUNTED STOP LAMP

REMOVAL

(1) Open liftgate.
(2) Remove liftgate CHMSL cover (Fig. 6).
(3) Unsnap and remove the CHMSL lens from the lamp housing.
(4) Pull bulb(s) from the lamp housing.

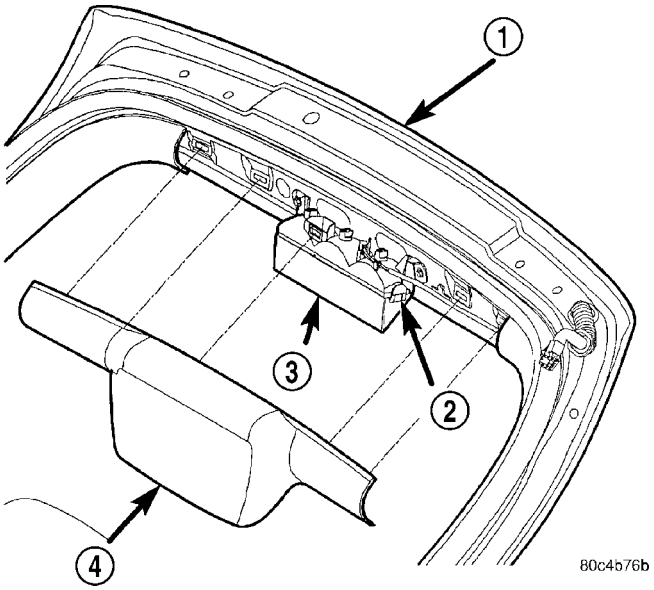

Fig. 6 CENTER HIGH MOUNTED STOP LAMP AND COVER

1 - LIFTGATE
2 - SNAP
3 - CHMSL LAMP
4 - CHMSL COVER

INSTALLATION

(1) Install bulb(s) into the lamp housing (Fig. 6).
(2) Snap the CHMSL lens onto the lamp housing.
(3) Test operation of lamps.
(4) Install liftgate CHMSL cover.
(5) Close liftgate.

CENTER HIGH MOUNTED STOP LAMP UNIT

REMOVAL

(1) Open liftgate.
(2) Remove liftgate CHMSL cover (Fig. 6).
(3) Disconnect the wire harness from the CHMSL.
(4) Remove screws attaching the CHMSL unit (Fig. 7).

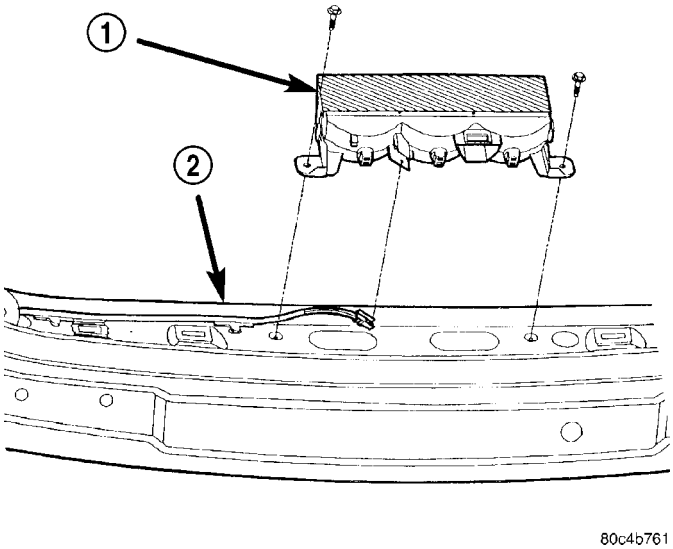

Fig. 7 CENTER HIGH MOUNTED STOP LAMP UNIT

1 - CHMSL LAMP
2 - LIFTGATE

(5) Remove the CHMSL unit from vehicle.

INSTALLATION

(1) Engage the wire harness connector to the CHMSL.
(2) Instal screws attaching the CHMSL unit (Fig. 7).
(3) Test operation of lamps.
(4) Install liftgate CHMSL cover.
(5) Close liftgate.

CENTER HIGH MOUNTED STOP LAMP UNIT - PT27

REMOVAL

(1) Open hood.
(2) Disconnect and isolate the battery negative cable.
(3) Open decklid.
(4) Remove the decklid trim panel (Refer to 23 - BODY/DECKLID/HATCH/LIFTGATE/TAILGATE/ TRIM PANEL - REMOVAL).
(5) Disconnect the Center High Mounted Stop Lamp (CHMSL) Unit electrical connector (Fig. 8).
(6) Remove the two retaining nuts to the CHMSL Unit (Fig. 9) and (Fig. 10).
(7) Remove CHMSL Unit from decklid.

INSTALLATION

(1) Position Center High Mounted Stop Lamp (CHMSL) Unit onto decklid.

CENTER HIGH MOUNTED STOP LAMP UNIT - PT27 (Continued)

COMBINATION FLASHER

DESCRIPTION

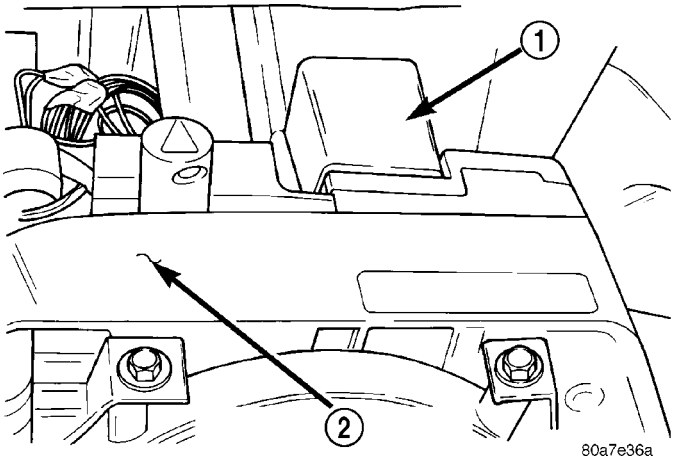

Fig. 11 COMBINATION FLASHER

1 - COMBINATION FLASHER
2 - MULTI-FUNCTION SWITCH

The turn signal flasher and the hazard warning flasher are combined into one unit called a Combination Flasher (combo-flasher). The combo-flasher is a smart relay located on the back of the multi-function switch (Fig. 11). The combo-flasher is black in color and has a dampener material wrapped on it.

OPERATION

The combo-flasher controls the flashing of the hazard warning system and the turn signal system. Constant battery voltage is supplied to the flasher so that it can perform the hazard warning function, and

COMBINATION FLASHER (Continued)

ignition switched battery voltage is supplied for the turn signal function. However, when the flasher is idle no current is drawn through the module. The unit does not become active until it is provided a signal ground from the turn signal switch or hazard warning switch. An inoperative bulb or incomplete turn signal circuit will cause the flasher rate to double. Typical flash rate is about ninety flashes per minute. When a bulb is burnt out, or when a circuit for a lamp is open, the turn signal flash rate will increase to a minimum of 180 flashes per minute. However, an open lamp circuit or burnt out bulb does not change the hazard warning flash rate.

Turn signal inputs that actuate the combination flasher are low current grounds, each drawing a maximum of 300 milliamperes. The turn signal inputs are provided to the flasher through the multi-function switch on the steering column. The hazard warning signal input is a low current ground drawing a maximum of 600 milliamperes. The hazard warning input can be provided through the multi-function switch on the steering column.

REMOVAL

The flasher is mounted to the back side of the multi-function switch (Fig. 11). The flasher is serviced separately from the multi-function switch.

(1) Open hood.

(2) Disconnect and isolate the battery negative cable.

(3) Remove the upper steering column shroud.

(4) The flasher can be removed by pulling it toward the instrument cluster (forward) (Fig. 11).

INSTALLATION

The flasher is mounted to the back side of the multi-function switch (Fig. 11). The flasher is serviced separately from the multi-function switch.

(1) Align the combo-flasher tabs and push into place (Fig. 11).

(2) Install the upper steering column shroud.

(3) Connect the battery negative cable.

(4) Close hood.

(5) Verify vehicle and system operation.

DAYTIME RUNNING LAMP MODULE

DESCRIPTION

Vehicles built for use in Canada are equipped with a Daytime Running Lamp (DRL) system. Turn signal lamp circuitry always comes from the multi-function switch, and goes to the cluster connector, into the cluster, then back out to the front turn signal switch lamps.

OPERATION

The Canadian cluster provides steady illumination of the front turn signal when the ignition switch is in the ON position. The DRL function may be inhibited by activating the turn signals, the hazard flashers, the headlamp switch, or park brake.

FOG LAMP

DIAGNOSIS AND TESTING - FOG LAMP

FOG LAMP DIAGNOSIS

CONDITION	POSSIBLE CAUSES	CORRECTION
FOG LAMPS ARE DIM WITH ENGINE IDLING OR IGNITION TURNED OFF.	1. Loose or corroded battery cables.	1. Clean and secure battery cable clamps and posts.
	2. Loose or worn generator drive belt.	2. Adjust or replace generator drive belt.
	3. Charging system output too low.	3. Test and repair charging system. Refer to Charging System.
	4. Battery has insufficient charge.	4. Test battery state - of - charge. Refer to Battery.
	5. Battery is sulfated or shorted.	5. Load test battery. Refer to Battery.
	6. Poor lighting circuit Z1-ground.	6. Test for voltage drop across Z1-ground locations. Refer to Wiring Diagnosis.

FOG LAMP (Continued)

CONDITION	POSSIBLE CAUSES	CORRECTION
FOG LAMP BULBS BURN OUT FREQUENTLY.	1. Charging system output too high.	1. Test and repair charging system. Refer to Charging System.
	2. Loose or corroded terminals or splices in circuit.	2. Inspect and repair all connectors and splices. Refer to Wiring Diagnosis.
FOG LAMPS ARE DIM WITH ENGINE RUNNING ABOVE IDLE.	1. Charging system output too low.	1. Test and repair charging system. Refer to Charging System.
	2. Poor lighting circuit Z1-ground.	2. Test for voltage drop across Z1-ground locations. Refer to Wiring Diagnosis.
	3. High resistance in fog lamp circuit.	3. Test amperage draw of fog lamp circuit.
FOG LAMPS FLASH RANDOMLY.	1. Poor lighting circuit Z1-ground.	1. Test for voltage drop across Wiring Diagnosis.
	2. High resistance in fog lamp circuit.	2. Test amperage draw of fog lamp circuit.
	3. Faulty fog lamp switch.	3. Replace fog lamp switch.
	4. Loose or corroded terminals or splices in circuit.	4. Inspect and repair all connectors and splices. Refer to Wiring Diagnosis.
FOG LAMPS DO NOT ILLUMINATE	1. Blown fuse for fog lamp.	1. Replace fuse. Refer to Wiring Diagnosis.
	2. No Z1-ground at fog lamps.	2. Repair circuit ground. Refer to Wiring Diagnosis.
	3. Faulty fog lamp switch.	3. Replace fog lamp switch.
	4. Broken connector terminal or wire splice in fog lamp circuit.	4. Repair connector terminal or wire splice.
	5. Defective or burned out bulb.	5. Replace bulb.

REMOVAL

(1) Reach behind the lower splash shield to gain access to the rear of the fog lamp (Fig. 12).
(2) Disconnect wire connector from fog lamp.
(3) Remove bulb from lamp.

INSTALLATION

CAUTION: Do not touch the glass of halogen bulbs with fingers or other possibly oily surface, reduced bulb life will result.

(1) Install bulb into lamp (Fig. 12).
(2) Connect wire connector to the fog lamp. Test operation of lamp.
(3) Install splash shield attaching fasteners.

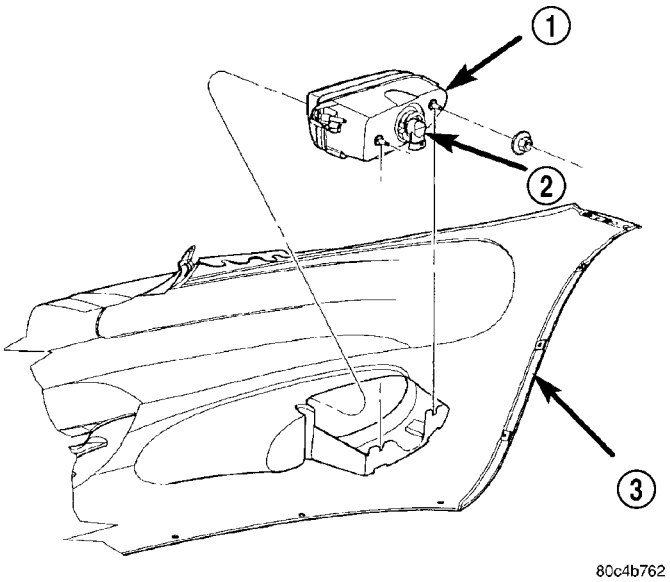

Fig. 12 FOG LAMP

1 - FOG LAMP ADAPTER
2 - FOG LAMP BULB
3 - FRONT FASCIA

FOG LAMP UNIT

STANDARD PROCEDURE - FOG LAMP UNIT ALIGNMENT

Prepare an alignment screen (Refer to 8 - ELECTRICAL/LAMPS/LIGHTING - EXTERIOR/HEADLAMP UNIT - STANDARD PROCEDURE) and read the Alignment Screen Preparation paragraph. Turn on the headlamp switch to the parking lamps only position and actuate the fog lamp switch. A properly aligned fog lamp will project a pattern on the alignment screen with the top of the cut-off line 10 cm (4 in.) below the fog lamp center line and straight ahead with the vehicle 25 feet from the alignment screen.

To adjust fog lamp unit alignment, rotate the alignment screw located on the side of the fog lamp unit from the cooling opening in the fascia, just inboard of the fog lamp opening, to achieve the specified pattern position (Fig. 13).

REMOVAL

(1) Remove fasteners attaching lower splash shield to gain access to the rear of the fog lamp (Fig. 12).

(2) Disconnect wire connector from fog lamp.

(3) Remove nuts attaching fog lamp to fascia.

(4) Remove lamp from fascia. The lower horn may need to be removed for easier fog lamp unit removal.

(5) Remove the two fasteners attaching the outboard end of the fascia to the fender.

(6) Rotate fog lamp unit forward, up, and out.

INSTALLATION

CAUTION: Do not touch the glass of halogen bulbs with fingers or other possibly oily surface, reduced bulb life will result.

(1) Rotate fog lamp unit into position.

(2) Place fog lamp unit into position.

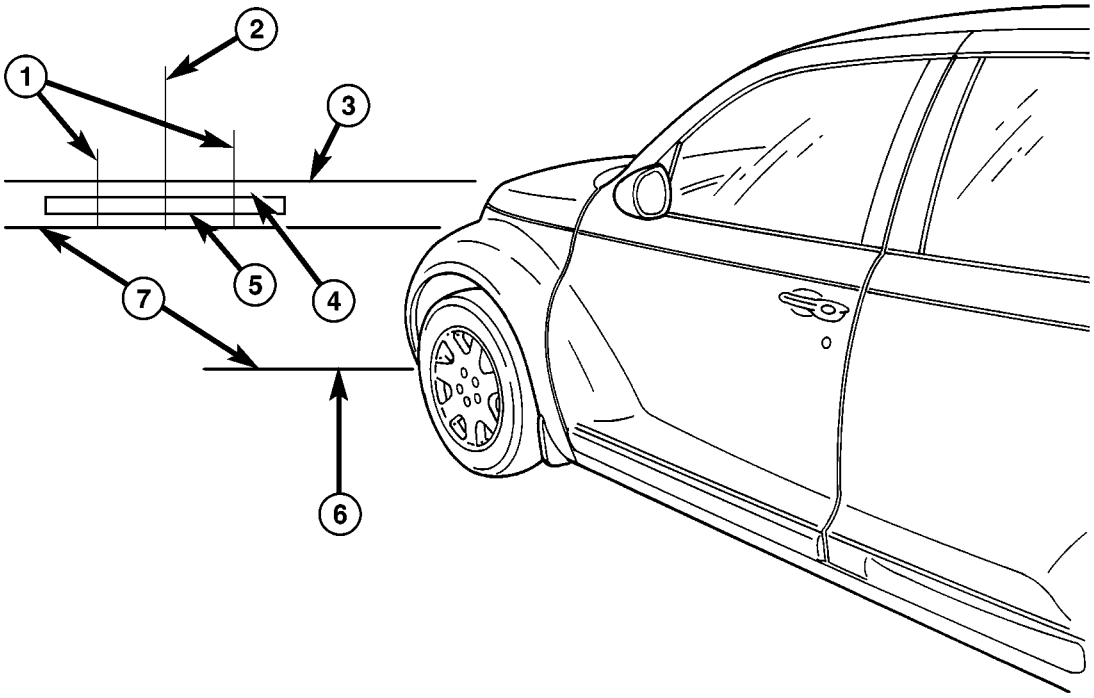
(3) Ensure that the three locating tabs molded into the fog lamp adapter are seated in the three matching fascia slots.

(4) Install nuts attaching fog lamp to fascia.

(5) Connect wire connector to the fog lamp.

(6) Install horn if removed.

(7) Install two fasteners to hold the outboard end of the fascia to the fender.



80d8b54c

Fig. 13 FOG LAMP UNIT ALIGNMENT SCREEN

HEADLAMP

DIAGNOSIS AND TESTING - HEADLAMPS

Always begin any diagnosis by testing all of the fuses and circuit breakers in the system. Refer to Wiring Diagrams.

HEADLAMP DIAGNOSIS

CONDITION	POSSIBLE CAUSES	CORRECTION
HEADLAMPS ARE DIM WITH ENGINE IDLING OR IGNITION TURNED OFF.	1. Loose or corroded battery cables.	1. Clean and secure battery cable clamps and posts.
	2. Loose or worn generator drive belt.	2. Adjust or replace generator drive belt.
	3. Charging system output too low.	3. Test and repair charging system. Refer to Charging System.
	4. Battery has insufficient charge.	4. Test battery state - of - charge. Refer to Battery.
	5. Battery is sulfated or shorted.	5. Load test battery. Refer to Battery.
	6. Poor lighting circuit Z1 - ground.	6. Test for voltage drop across Z1 - ground locations. Refer to Wiring Diagrams.
	7. Both headlamp bulbs defective.	7. Replace both headlamp bulbs.
HEADLAMP BULBS BURN OUT FREQUENTLY.	1. Charging system output too high.	1. Test and repair charging system. Refer to Charging System.
	2. Loose or corroded terminals or splices in circuit.	2. Inspect and repair all connectors and splices. Refer to Wiring Diagrams.
HEADLAMPS ARE DIM WITH ENGINE RUNNING EVEN ABOVE IDLE.*	1. Charging system output too low.	1. Test and repair charging system. Refer to Charging Systems.
	2. Poor lighting circuit Z1 - ground.	2. Test for voltage drop across Z1 - ground locations. Refer to Wiring Diagrams.
	3. High resistance in headlamp circuit.	3. Test amperage draw of headlamp circuit.
	4. Both headlamp bulbs defective.	4. Replace both headlamp bulbs.
HEADLAMPS FLASH RANDOMLY.	1. Poor lighting circuit Z1 - ground.	1. Test for voltage drop across Z1 - ground locations. Refer to Wiring Diagrams.
	2. High resistance in headlamp circuit.	2. Test amperage draw of headlamp circuit. Should not exceed 30 amps.
	3. Faulty headlamps switch circuit breaker.	3. Replace headlamp switch.
	4. Loose or corroded terminals or splices in circuit.	4. Inspect and repair all connectors and splices. Refer to Wiring Diagrams.

HEADLAMP (Continued)

CONDITION	POSSIBLE CAUSES	CORRECTION
HEADLAMPS DO NOT ILLUMINATE.	1. No voltage to headlamps.	1. Repair open headlamp circuit. Refer to Wiring Diagrams.
	2. No Z1 - ground at headlamps.	2. Repair circuit ground. Refer to Wiring Diagrams.
	3. Faulty headlamp switch.	3. Replace headlamp switch.
	4. Faulty headlamp dimmer (multi-function) switch.	4. Replace multi-function switch.
	5. Broken connector terminal or wire splice in headlamp circuit.	5. Repair connector terminal or wire splice.
(DRL EQUIPPED VEHICLES) HEADLAMPS STAY ON WITH KEY REMOVED.	Failed DRL module.	Replace DRL module.
*Canada vehicles must have lamps ON.		

REMOVAL

(1) Remove headlamp access cover in splash shield (Fig. 14).

(2) Rotate socket counterclockwise one quarter turn.

(3) Remove bulb and socket from headlamp housing.

(4) Disconnect wire connector from back of headlamp high or low beam bulb.

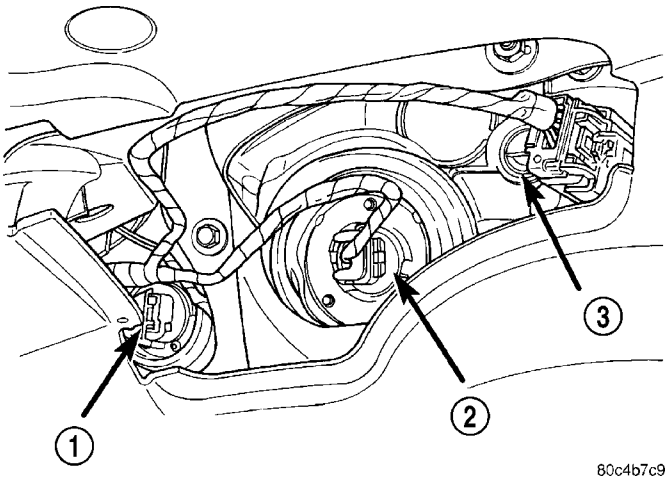

Fig. 14 HEADLAMP BULB ACCESS

1 - HIGH BEAM LAMP
2 - LOW BEAM LAMP
3 - PARK/TURN SIGNAL LAMP

INSTALLATION

CAUTION: Do not touch the glass of halogen bulbs with fingers or other possibly oily surface, reduced bulb life will result.

(1) Connect wire connector to the back of headlamp high or low beam bulb.

(2) Install bulb into headlamp housing (Fig. 14)

(3) Rotate socket clockwise one quarter turn.

(4) Test operation of lamps.

(5) Install headlamp access cover into splash shield.

HEADLAMP UNIT

STANDARD PROCEDURE - HEADLAMP UNIT ALIGNMENT

ALIGNMENT SCREEN PREPARATION

(1) Position vehicle on a level surface perpendicular to a flat wall 7.62 meters (25 ft.) away from front of headlamp lens.

(2) If necessary, tape a line on the floor 7.62 meters (25 ft.) away from and parallel to the wall (Fig. 15).

HEADLAMP UNIT (Continued)

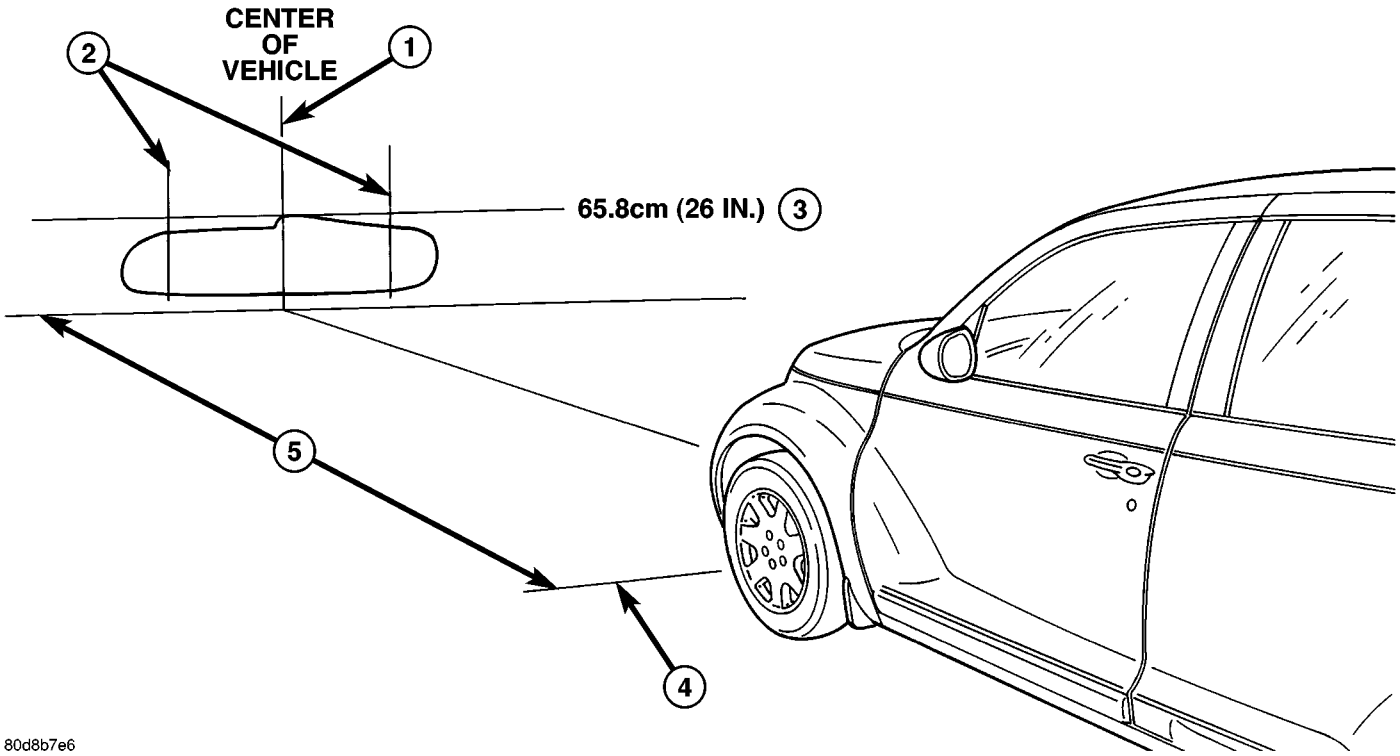

Fig. 15 HEADLAMP UNIT ALIGNMENT SCREEN

1 - CENTER OF VEHICLE
2 - CENTER OF HEADLAMPS
3 - 65.8cm (26 IN.) OR HEIGHT OF LOW BEAM DOT ON FOG LAMP UNIT LENS
4 - FRONT OF HEADLAMP
5 - 7.62 METERS (25 FT.)

(3) From the floor up 65.8 Centimeters (26 in.), tape a vertical line on the wall at the center line of the vehicle. Sight along the center line of the vehicle (from rear of vehicle forward) to verify accuracy of the line placement.

(4) Rock vehicle side-to-side three times to allow suspension to stabilize.

(5) Jounce front suspension three times by pushing downward on front bumper and releasing.

(6) A small dot is molded into each headlamp lens signifying the center of the low-beam headlamp. Measure the distance from the center of the headlamp to the floor. Transfer measurement to the alignment screen (with tape). Use this line for up/down adjustment reference.

HEADLAMP UNIT ALIGNMENT

The headlamp low beam pattern has a distinct horizontal cutoff line which is used to visually align the headlamps. A properly aimed headlamp will have the top of the horizontal cut off line of the low beam pattern aligned with the horizontal line on the wall (Fig. 15). The high beams on a vehicle with aero headlamps cannot be aligned. The high beam pattern should be correct when the low beams are aligned properly.

To adjust headlamp unit alignment, rotate alignment screw to achieve the specified low beam hot spot pattern.

HEADLAMP UNIT (Continued)

REMOVAL

(1) Raise vehicle on a hoist.
(2) Remove wheel and tire.
(3) Remove splash shield as necessary to access headlamp housing.
(4) Remove grille.
(5) Remove the two fascia bolts from behind the grille (Fig. 16) and (Fig. 17).
(6) Remove fasteners attaching fender to fascia on the side being worked on.
(7) Remove the three fasteners holding the lower fascia to the lower radiator crossmember.
(8) Remove four nuts attaching headlamp housing (Fig. 18).
(9) Remove headlamp housing by lowering the fascia as necessary (Fig. 19) and (Fig. 20).
(10) Disconnect wire connector.

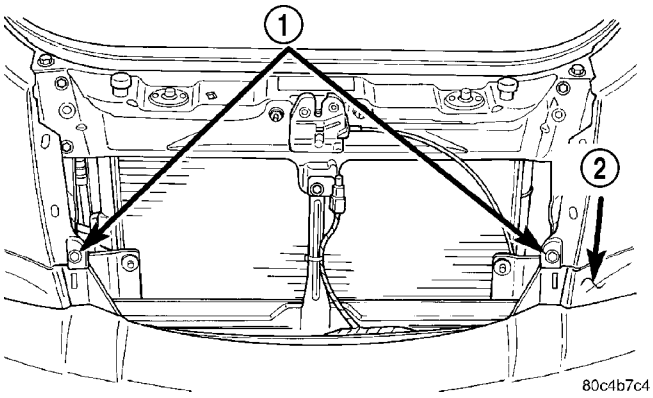

Fig. 16 FASCIA CENTER ATTACHING POINT

1 - ATTACHING POINTS
2 - FRONT FASCIA

INSTALLATION

CAUTION: Do not touch the glass of halogen bulbs with fingers or other possibly oily surface, reduced bulb life will result.

(1) Connect wire connectors to the back of headlamp housing.
(2) Place headlamp housing in to position, lower fascia as necessary to install headlamp housing in to position (Fig. 20) and (Fig. 19). Tilt headlamp unit to opening as necessary.

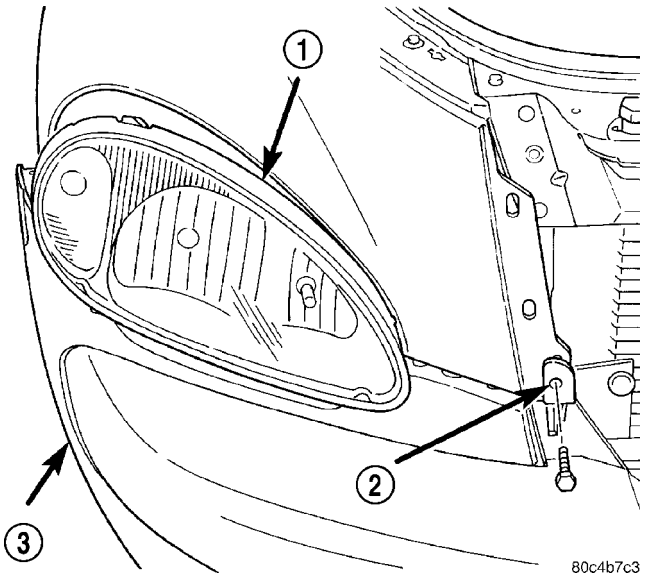

Fig. 17 LOOSENING THE FASCIA

2 - FRONT SIDE MARKER/PARK/TURN SIGNAL LAMP
3 - MOUNTING HOLES
4 - HEADLAMP HOUSING
5 - LOW BEAM CONNECTOR
6 - MOUNTING HOLE
7 - HIGH BEAM CONNECTOR

(3) Install nut(s) attaching headlamp housing (Fig. 18).
(4) Test lamp operation.
(5) Install fasteners attaching fender to fascia on the side being work on.
(6) Install the two fascia bolts from behind the grille (Fig. 16) and (Fig. 17).
(7) Install three fasteners to hold the lower fascia to the lower radiator crossmember.
(8) Install grille.
(9) Install splash shield as necessary to access headlamp housing.
(10) Install wheel and tire.
(11) Lower vehicle.

HEADLAMP SWITCH

DESCRIPTION

The headlamp switch is integral to the left stalk of the multi-function switch (Fig. 22), on the steering column, behind the steering wheel. A knob on the end of the left control stalk controls all of the exterior lighting functions.

OPERATION

Turn the end of the control lever to the first detent for parking light operation and for headlamp operation, to the second detent. To activate the front fog lights, turn ON the parking lights or the low beam headlights and pull out the end of the control lever.

The headlamp switch is part of the multi-function switch (Refer to 8 - ELECTRICAL/LAMPS/LIGHTING - EXTERIOR/MULTI-FUNCTION SWITCH - DIAGNOSIS AND TESTING). The headlamp switch cannot be repaired. If found defective, it must be replaced.

LICENSE PLATE LAMP

REMOVAL

(1) Remove screws attaching license plate lamp to rear bumper (Fig. 21).
(2) Remove lamp from bumper.
(3) Remove bulb socket from lamp housing.
(4) Pull bulb from socket.

LICENSE PLATE LAMP (Continued)

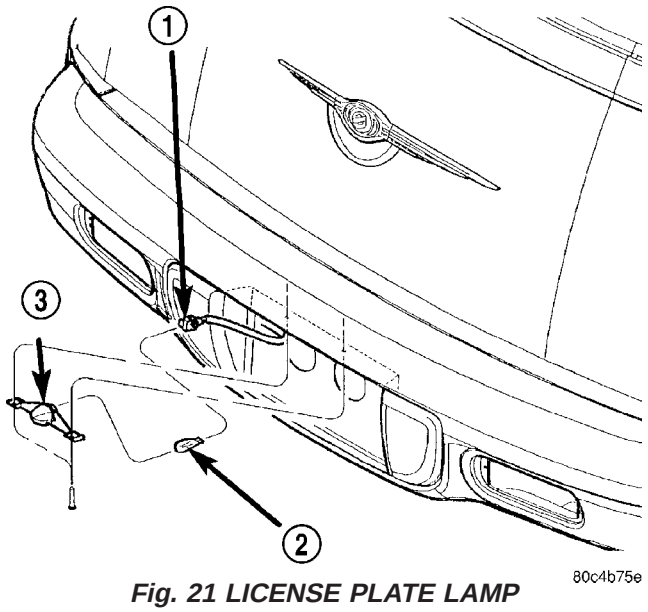

Fig. 21 LICENSE PLATE LAMP

1 - CONNECTOR
2 - BULB
3 - LICENSE PLATE LAMP

INSTALLATION

(1) Install bulb into socket (Fig. 21).
(2) Install bulb socket into lamp.
(3) Place lamp in position.
(4) Install screws attaching license plate lamp to rear bumper.

LICENSE PLATE LAMP UNIT

REMOVAL

(1) Remove screws attaching license plate lamp to rear bumper (Fig. 21).
(2) Remove lamp from bumper.
(3) Disconnect wire connector and bulb.

INSTALLATION

(1) Connect wire connector and bulb (Fig. 21).
(2) Place lamp in position.
(3) Install screws attaching license plate lamp to rear bumper.

MULTI-FUNCTION SWITCH

DESCRIPTION

MULTI-FUNCTION SWITCH

The turn signals are part of the multi-function switch which contains (Fig. 22):

- Electrical circuitry for turn signals
- Hazard warning switch
- Headlamp switch
- Fog Lamp Switch
- Headlamp beam select switch
- Optical Horn
- Instrument Panel Lamp Dimmer/Interior Lamp Switch

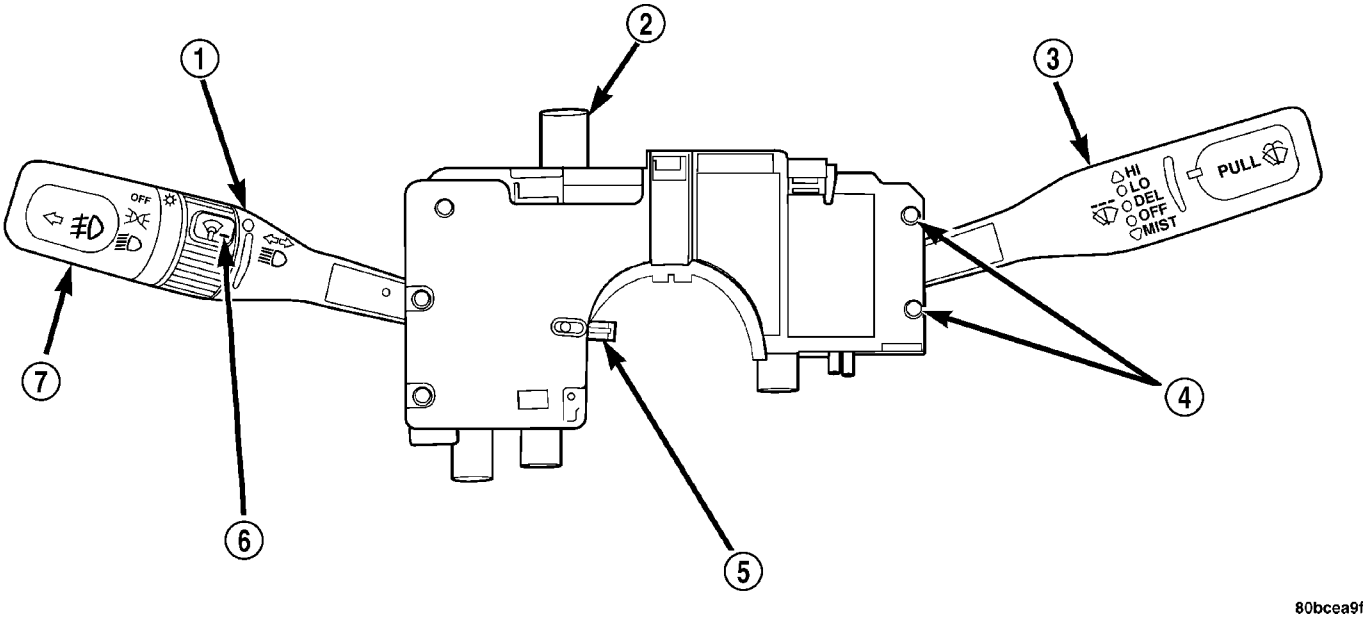

Fig. 22 MULTI-FUNCTION SWITCH

1 - TURN SIGNAL CONTROL STALK
2 - HAZARD WARNING SWITCH
3 - WINDSHIELD WIPER/WASHER CONTROL
4 - WINDSHIELD WIPER/WASHER SWITCH RETAINING SCREWS
5 - CANCELLING CAM
6 - PANEL DIMMER/INTERIOR LIGHT SWITCH
7 - EXTERIOR LIGHTING CONTROL/FOG LAMP

MULTI-FUNCTION SWITCH (Continued)

- Combination Flasher

The integrated turn signal switch assembly is mounted to the left hand side of the steering column.

HAZARD WARNING SYSTEM

The hazard warning system is actuated by a push button located in the multi-function switch (Fig. 22) on the top of the steering column between the steering wheel and the instrument panel. The hazard switch is identified with a double triangle on front of the button.

The hazard warning system allows the vehicle operator to provide the drivers of other vehicles in near proximity an optical indication that the vehicle is disabled or is an obstacle to traffic flow. Unlike the turn signal system, the hazard warning system has battery current at all times, regardless of ignition switch position.

OPERATION

MULTI-FUNCTION SWITCH

When the driver wishes to signal his intentions to change direction of travel, he moves the lever upward to cause the right signals to flash and downward to cause the left signals to flash. After completion of a turn the system is deactivated automatically. As the steering wheel returns to the straight ahead position, a canceling cam molded to the clockspring mechanism comes in contact with the cancel actuator on the turn signal multi-function switch assembly. The cam lobe, pushing on the cancel actuator, returns the switch to the off position.

If only momentary signaling such as indication of a lane change is desired, the switch is actuated to a left or right intermediate detent position. In this position the signal lamps flash as described above, but the switch returns to the OFF position as soon as the lever is released.

When the system is activated, one of two indicator lamps mounted in the instrument cluster flashes in unison with the turn signal lamps, indicating to the driver that the system is operating.

HAZARD WARNING SYSTEM

When the hazard warning system is activated, the combination flasher will cause both the right and left side turn signal indicator lamps, front park/turn signal lamps, front side marker lamps and rear turn signal lamps to flash on and off. If the exterior lamps are turned off, the front park/turn signal lamps and the front side marker lamps will flash in unison. If the exterior lamps are turned on, the front park/turn signal lamps and the side marker lamps will flash alternately.

DIAGNOSIS AND TESTING - MULTI-FUNCTION SWITCH

FLASHER DIAGNOSIS

Should any function of the multi-function switch fail, the entire switch assembly must be replaced (Refer to 8 - ELECTRICAL/LAMPS/LIGHTING - EXTERIOR/MULTI-FUNCTION SWITCH - REMOVAL).

TURN SIGNAL AND FLASHER DIAGNOSIS

CONDITION	POSSIBLE CAUSES	CORRECTION
TURN SIGNAL FLASHES AT TWICE THE NORMAL RATE.	(1) FAULTY EXTERNAL LAMP.	(1) REPLACE LAMP.
	(2) POOR GROUND AT LAMP.	(2) CHECK AND/OR REPAIR WIRING.
	(3) OPEN CIRCUIT IN WIRING TO EXTERNAL LAMP.	(3) REPAIR WIRING HARNESS. CHECK CONNECTORS.
	(4) FAULTY CONTACT IN SWITCH.	(4) REPLACE MULTI FUNCTION SWITCH.
INDICATOR LAMP ILLUMINATED BRIGHTLY, EXTERNAL LAMP GLOWS DIMLY AT A RAPID RATE.	(1) LOOSE OR CORRODED EXTERNAL LAMP CONNECTION.	(1) REPLACE SOCKET CONNECTION.
	(2) POOR GROUND CIRCUIT AT EXTERNAL LAMP.	(2) REPAIR WIRING HARNESS. CHECK CONNECTORS.
	(3) OPEN INSTRUMENT CLUSTER.	(3) REPLACE INSTRUMENT CLUSTER.

MULTI-FUNCTION SWITCH (Continued)

CONDITION	POSSIBLE CAUSES	CORRECTION
HAZARD WARNING SYSTEM DOES NOT FLASH.	(1) FAULTY FUSE.	(1) REPLACE FUSE.
	(2) FAULTY FLASHER.	(2) REPLACE FLASHER.
	(3) OPEN CIRCUIT IN FEED WIRE TO SWITCH.	(3) REPAIR WIRING HARNESS, CHECK CONNECTORS.
	(4) FAULTY CONTACT IN SWITCH.	(4) REPLACE MULTI FUNCTION SWITCH.
	(5) OPEN OR GROUNDED CIRCUIT IN WIRING TO EXTERNAL LAMPS.	(5) REPAIR WIRING HARNESS.
INDICATOR LAMP ILLUMINATES BRIGHTLY, EXTERNAL LAMP DOES NOT LIGHT.	(1) OPEN CIRCUIT IN WIRE TO EXTERNAL LAMP.	(1) REPAIR WIRING HARNESS.
	(2) BURNED OUT LAMP.	(2) REPLACE LAMP.
SYSTEM DOES NOT FLASH ON EITHER SIDE.	(1) FAULTY FUSE.	(1) REPLACE FUSE.
	(2) FAULTY FLASHER UNIT.	(2) REPLACE FLASHER.
	(3) LOOSE BULKHEAD CONNECTOR.	(3) TIGHTEN CONNECTOR.
	(4) LOOSE OR FAULTY REAR WIRING HARNESS OR TERMINALS.	(4) REPAIR WIRING HARNESS.
	(5) OPEN CIRCUIT TO FLASHER UNIT.	(5) CHECK CONNECTORS, REPAIR WIRING HARNESS.
	(6) OPEN CIRCUIT IN FEED WIRE TO TURN SIGNAL SWITCH.	(6) CHECK CONNECTORS, REPAIR WIRING HARNESS.
	(7) FAULTY SWITCH CONNECTION IN SWITCH.	(7) REPLACE MULTI FUNCTION SWITCH.
	(8) OPEN OR GROUNDED CIRCUIT IN WIRING TO EXTERNAL LAMPS.	(8) REPAIR WIRING HARNESS.
SYSTEM DOES NOT CANCEL AFTER COMPLETION OF THE TURN.	(1) BROKEN CANCELLING FINGER ON SWITCH.	(1) REPLACE MULTI FUNCTION SWITCH.
	(2) BROKEN OR MISSING CANCELLING CAM ON CLOCKSPRING.	(2) REPLACE CLOCKSPRING.
EXTERNAL LAMPS OPERATE PROPERLY, NO INDICATOR LAMP OPERATION.	(1) FAULTY INDICATOR LAMP IN INSTRUMENT CLUSTER.	(1) REPLACE LAMP.
	(2) OPEN CIRCUIT OR WIRING.	(2) REPAIR WIRING HARNESS.

MULTI-FUNCTION SWITCH (Continued)

SWITCH DIAGNOSIS

(1) Disconnect and isolate the battery negative cable (Fig. 23).

(2) Remove the upper and lower steering column shrouds.

(3) Disconnect the switch connector.

Using an ohmmeter, test for continuity between the terminals of the switch as shown in the MULTI-FUNCTION SWITCH CONTINUITY TEST table for diagnosis. Refer to (Fig. 24), (Fig. 25), and (Fig. 26) for connector terminal locations.

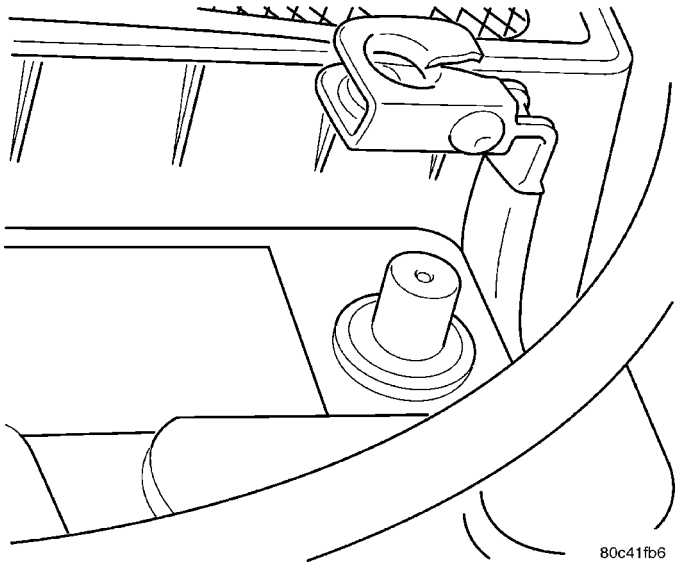

Fig. 23 BATTERY NEGATIVE CABLE REMOVE/ INSTALL

MULTI-FUNCTION SWITCH (Continued)

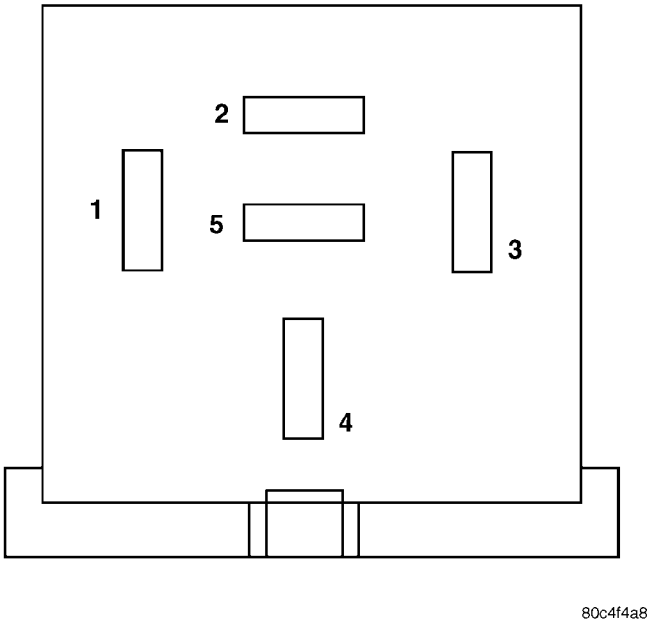

Fig. 24 COMBINATION FLASHER CONNECTOR (A)

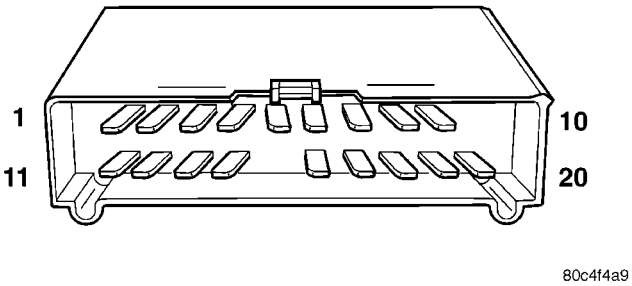

Fig. 25 MULTI-FUNCTION SWITCH CONNECTOR (B)

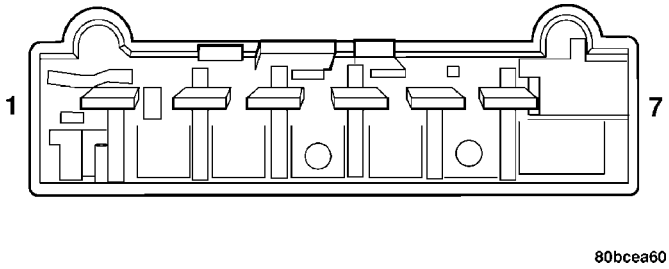

Fig. 26 WINDSHIELD WIPER/WASHER SWITCH CONNECTOR (C)

REMOVAL

(1) Open hood.

(2) Disconnect and isolate the battery negative cable (Fig. 23).

(3) Remove both upper and lower steering column shrouds.

(4) Disconnect both posi-lock harness connectors at the rear of the multi-function switch (Fig. 27)

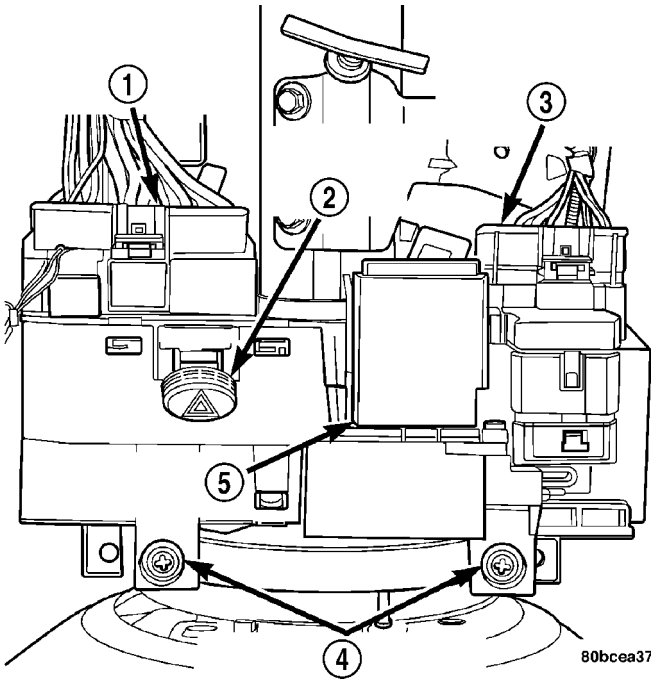

Fig. 27 MULTI-FUNCTION SWITCH REMOVE/ INSTALL

1 - MULTI-FUNCTION SWITCH CONNECTOR
2 - HAZARD/WARNING SWITCH
3 - WINDSHIELD WIPER/WASHER SWITCH CONNECTOR
4 - MOUNTING SCREWS
5 - COMBINATION FLASHER

(5) Remove multi-function switch mounting screws (Fig. 27) and remove switch from vehicle.

INSTALLATION

NOTE:
If replacing the multi-function switch, the combination flasher and windshield wiper/washer switch must be transferred to new multi-function switch. Remove the two torx screws retaining the wiper/ washer switch, place next to the new multi-function switch and install two screws.

(1) Place switch into place and install mounting screws (Fig. 27). Torque multi-function switch to column retaining screws to 3 N·m (27 in. lbs.).

(2) Connect both posi-lock harness connectors at the rear of the multi-function switch (Fig. 27)

(3) Install both upper and lower steering column shrouds.

(4) Connect the battery negative cable (Fig. 23).

(5) Close hood.

(6) Verify vehicle and system operation.

PARK/TURN SIGNAL LAMP

REMOVAL

(1) Remove headlamp access cover in splash shield (Fig. 28).

(2) Rotate socket counterclockwise one quarter turn.

(3) Remove bulb and socket from headlamp unit.

(4) Disconnect wire connector from back of front side marker/park/turn signal lamp.

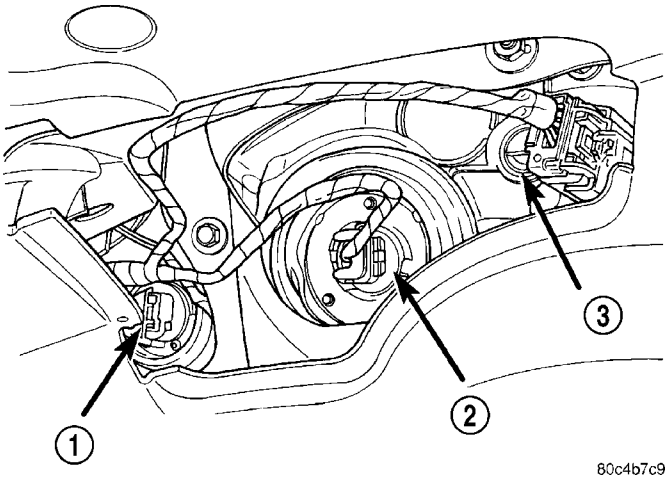

Fig. 28 HEADLAMP ACCESS

1 - HIGH BEAM LAMP
2 - LOW BEAM LAMP
3 - PARK/TURN SIGNAL LAMP

INSTALLATION

(1) Connect wire connector to the back of front side marker/park/turn signal lamp.

(2) Install bulb into headlamp unit (Fig. 28)

(3) Rotate socket clockwise one quarter turn.

(4) Test operation of lamps.

(5) Install headlamp access cover into splash shield.

REAR FOG LAMP SWITCH - EXPORT

DESCRIPTION

The rear fog lamp switch is incorporated into the multi-function switch (Fig. 29).

OPERATION

The multi-function switch contains the added circuitry for the operation of the rear fog lamp switch. While in the front fog lights position, rotate the end of the left control stalk past the headlights position to activate the rear fog lights. (Refer to 8 - ELECTRICAL/LAMPS/LIGHTING - EXTERIOR/MULTI-FUNCTION SWITCH - DIAGNOSIS AND TESTING) for rear fog lamp diagnosis.

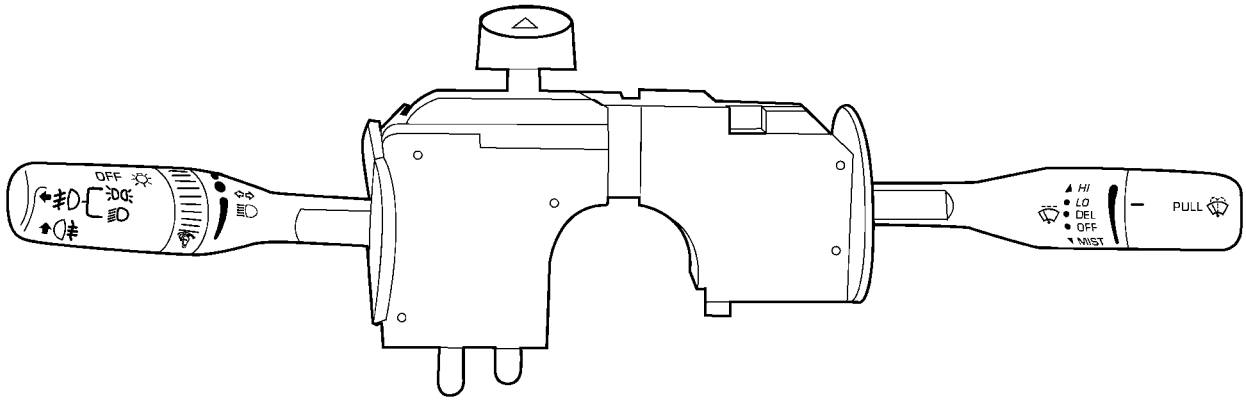

Fig. 29 MULTI-FUNCTION SWITCH WITH REAR FOG LAMP - EXPORT

TAIL LAMP

REMOVAL

(1) Remove screw attaching tail lamp assembly to the aperture panel (Fig. 30).

(2) Slide the lamp assembly down in the sheet metal opening.

(3) Remove the lamp assembly from vehicle.

(4) Remove bulb socket(s) from tail lamp housing.

(5) Pull bulb(s) from socket(s).

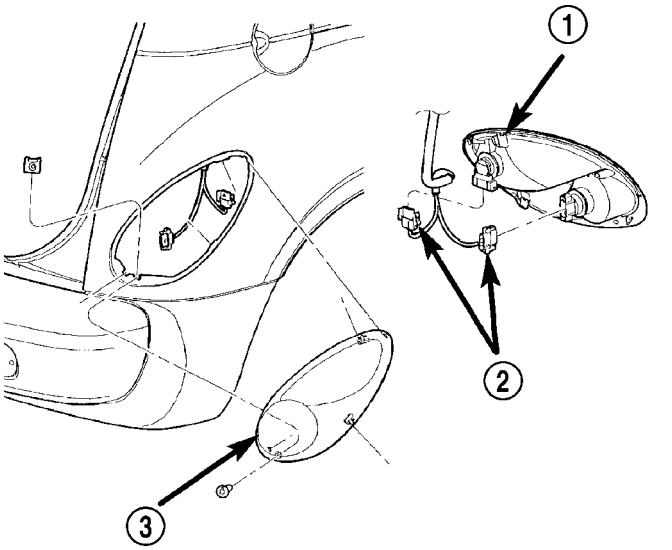

Fig. 30 TAIL AND STOP LAMPS

1 - TAIL LAMP HOUSING
2 - WIRE CONNECTORS
3 - BOTTOM LOCATOR

INSTALLATION

(1) Push bulb(s) into the bulb socket(s).

(2) Install bulb socket(s) into tail lamp assembly. Rotate the socket clockwise until fully seated.

(3) Test operation of lamps.

(4) Align the tail lamp assembly to the sheet metal opening.

(5) Insert the lower positioning tab into the slot and then rotate the lamp forward until the retaining clips snap into position.

(6) Slide the lamp assembly upwards within the opening.

(7) Install tail lamp attaching screw.

TAIL LAMP UNIT

REMOVAL

(1) Remove screw attaching tail lamp assembly to the aperture panel (Fig. 30).

(2) Slide the lamp assembly downward in the sheet metal opening.

(3) Remove the lamp assembly from the vehicle.

(4) Remove the bulb sockets from the lamp assembly by rotating the sockets counter-clockwise until free of the assembly.

INSTALLATION

(1) Install the bulb sockets to the lamp assembly by rotating the sockets clockwise until fully seated.

(2) Test operation of lamps.

(3) Align the tail lamp assembly to the sheet metal opening.

(4) Insert the lower positioning tab on the lamp assembly into the matching slot and rotate the lamp forward until the retaining clips snap into position.

(5) Slide the assembly upwards within the sheet metal opening.

(6) Install the screw to hold tail lamp assembly to the aperture panel.

All the interior bulbs utilize a brass or glass wedge base. Bulbs with aluminum bases are not approved and should not be used.

CENTER CONSOLE FLOOD LAMP

REMOVAL

(1) Open hood.
(2) Disconnect and isolate the battery negative cable.
(3) Insert a small screwdriver into notch by clip (Fig. 1)and gently pry out unit.
(4) Slide back rear cover to expose bulb.
(5) Replace bulb.

INSTALLATION

(1) Insert new bulb.
(2) Gently secure bulb back into slot.

NOTE: When installing the retainer, ensure that the forward tabs are inserted properly into the slots in the instrument panel.

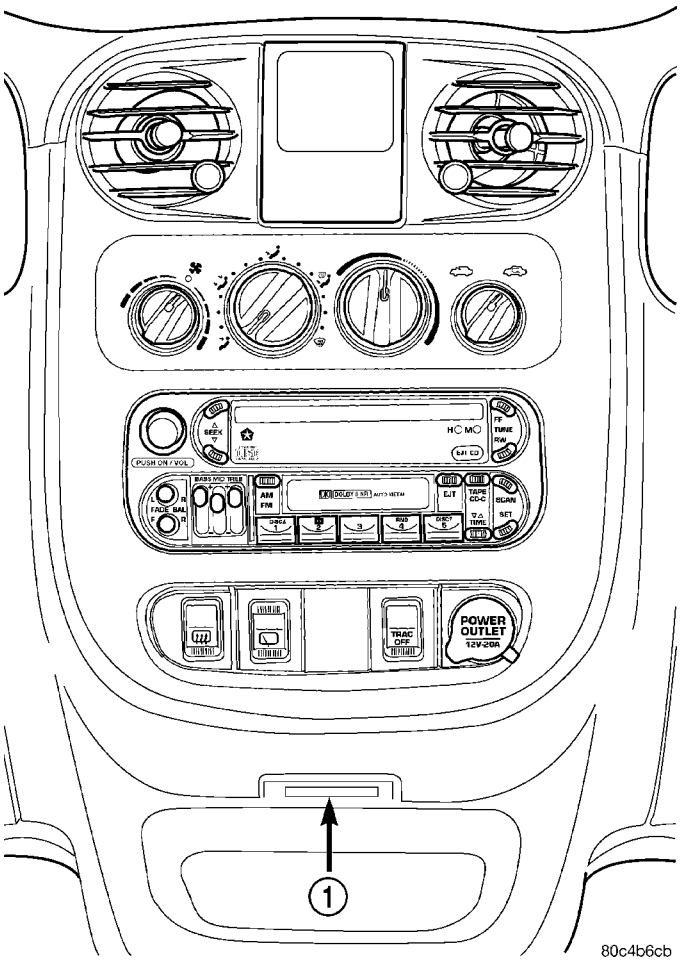

Fig. 1 CENTER CONSOLE FLOOD LAMP LOCATION

1 - CENTER CONSOLE FLOOD LAMP

(3) Connect the battery negative cable.
(4) Close hood.
(5) Verify vehicle and system operation.

CENTER CONSOLE FLOOD LAMP HOUSING

REMOVAL

(1) Using a flat blade tool, remove console flood lamp from the lower center console (Fig. 2).
(2) Disconnect wire connector.
(3) Remove console flood lamp housing.

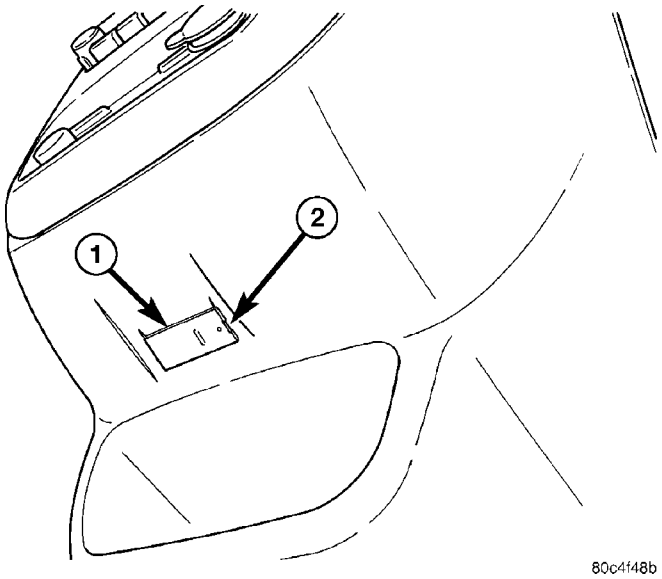

Fig. 2 LOWER INSTRUMENT PANEL CENTER STACK

1 - CONSOLE FLOOD LAMP
2 - INSERT SMALL FLAT TOOL

INSTALLATION

(1) Place console flood lamp housing near opening and connect the wire connector (Fig. 2).
(2) Test lamp.
(3) Place console flood lamp into position and apply hand pressure to snap lamp into position.

COURTESY/READING LAMP

REMOVAL

(1) Insert a trim stick between the lamp bezel and courtesy/readinglamp lens.
(2) Carefully swing down one side the lamp lens.
(3) Remove bulb from lamp socket.

INSTALLATION

(1) Push bulb in socket and snap into place.
(2) Position lens on lamp and snap into place.

DOME LAMP

REMOVAL

(1) Insert a trim stick between the lamp unit and the lens.
(2) Carefully swing down one side the lamp lens.
(3) Remove lamp from lamp unit socket.

INSTALLATION

(1) Push lamp in socket and snap into place.
(2) Position lens on lamp unit and snap into place.

DOME LAMP - PT27

REMOVAL

(1) Open hood.
(2) Disconnect and isolate the battery negative cable.
(3) Using a trim stick (special tool #C-4755) or equivalent, gently pry off the dome lamp cover from the sport bar (Fig. 3).

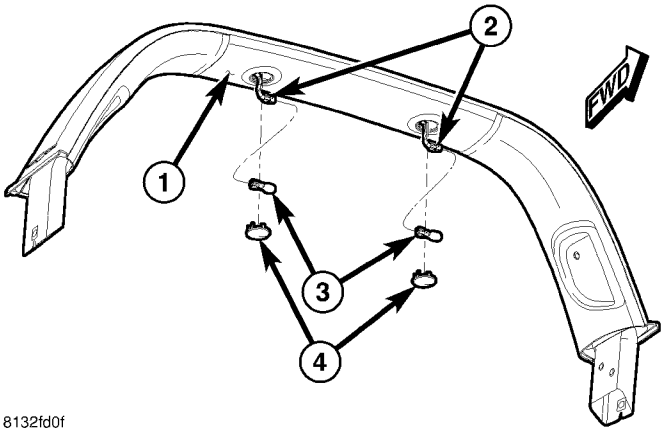

Fig. 3 DOME LAMPS - REMOVE/INSTALL

1 - SPORT BAR CENTER MOULDING
2 - DOME LAMP ELECTRICAL CONNECTORS
3 - DOME LAMPS
4 - DOME LAMPS COVERS

(4) Disconnect the dome lamp from the connector (Fig. 3).
(5) Remove lamp from vehicle.

INSTALLATION

(1) Remove lamp from vehicle.
(2) Connect the dome lamp to the connector (Fig. 3).
(3) Position the dome lamp cover on the sport bar (Fig. 3) and firmly push on cover to snap into place. The lens must be orientated correctly for proper fit.
(4) Connect the battery negative cable.
(5) Open hood.
(6) Verify vehicle and system operation.

DOME LAMP UNIT

REMOVAL

(1) Insert a trim stick between the dome lamp unit bezel and the headliner.
(2) Disconnect wire connector.
(3) Remove the dome lamp unit from vehicle.

INSTALLATION

(1) Place lamp into position.
(2) Connect electrical connector.
(3) Install dome lamp unit into headliner by firmly pushing upward.

CLUSTER ILLUMINATION LAMPS

REMOVAL

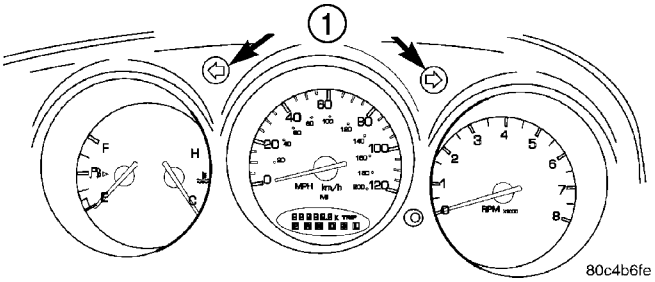

Fig. 4 TURN SIGNAL INDICATOR LAMPS

1 - TURN SIGNAL INDICATORS

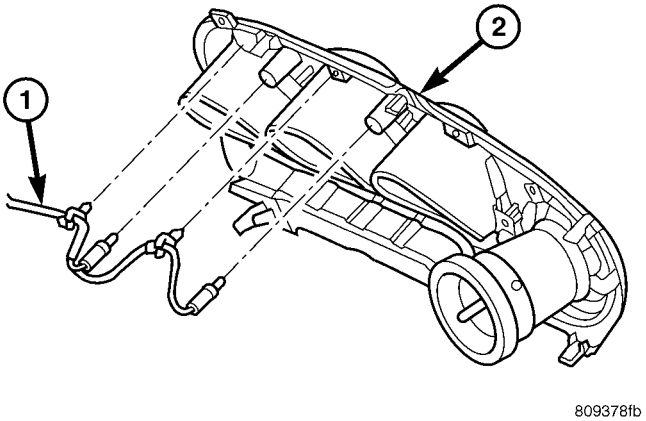

Fig. 5 TURN SIGNAL LAMP(S) - REMOVE/INSTALL

1 -CLUSTER BEZEL
2 - TURN SIGNAL LAMPS AND WIRE HARNESS

The instrument cluster turn signals (Fig. 5), (Fig. 4) and the high beam indicator (Fig. 6) are serviceable indicators. The instrument cluster must first be removed to replace the high beam indicator (Refer to 8 - ELECTRICAL/INSTRUMENT CLUSTER - REMOVAL). Then the defective bulb and socket turns out counterclockwise. The instrument cluster bezel needs to be removed to access the turn signal indicators (Refer to 23 - BODY/INSTRUMENT PANEL/CLUSTER BEZEL - REMOVAL). If any of the other indicators are burned out, the entire cluster must be replaced.

The cluster illumination bulbs are serviceable and may be replaced once the instrument cluster is removed (Refer to 8 - ELECTRICAL/INSTRUMENT CLUSTER - REMOVAL).

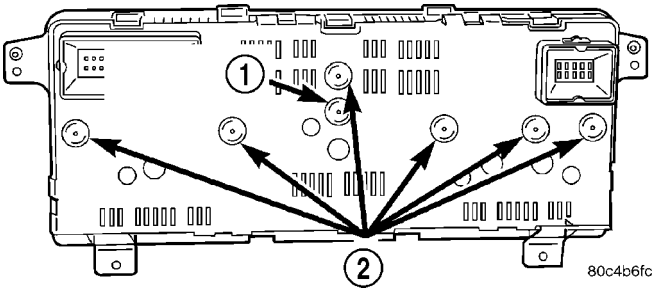

Fig. 6 INSTRUMENT CLUSTER ILLUMINATION BULBS

1 - HIGH BEAM INDICATOR
2 - ILLUMINATION BULBS

INSTALLATION

The illumination bulbs (Fig. 6) are serviceable. The bulb and socket turn in clockwise. Then the instrument cluster may be installed (Refer to 8 - ELECTRICAL/INSTRUMENT CLUSTER - INSTALLATION).

After servicing the indicator (high beam only), install the instrument cluster (Refer to 8 - ELECTRICAL/INSTRUMENT CLUSTER - INSTALLATION).

After replacing the turn signal bulb(s) (Fig. 5), install the (Refer to 23 - BODY/INSTRUMENT PANEL/CLUSTER BEZEL - INSTALLATION).

REAR CARGO LAMP

REMOVAL

(1) Open liftgate.
(2) Remove jack storage door from right rear quarter trim panel.
(3) Remove jack and tool bag.
(4) Place right hand on stem of cargo lamp unit and pull downward until lens separates from the lamp unit (Fig. 7).
(5) Pull cargo lamp unit through jack storage door opening to access bulb.
(6) Disconnect wire connector from cargo lamp unit.
(7) Pull bulb from unit socket.

INSTALLATION

(1) Push bulb into unit socket (Fig. 7).
(2) Snap lens onto lamp unit.

REAR CARGO LAMP (Continued)

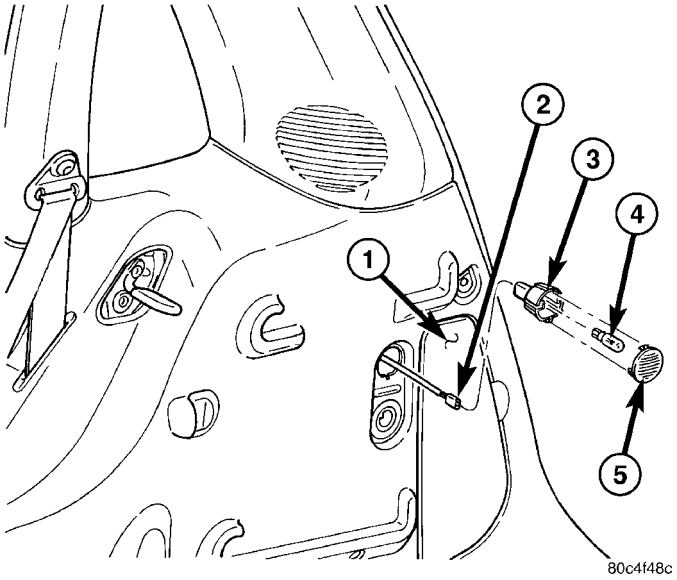

Fig. 7 REAR CARGO LAMP

1 - JACK STORAGE AREA
2 - WIRE CONNECTOR
3 - CARGO LAMP UNIT
4 - BULB
5 - LENS

(3) Move wire connector through lamp opening and connect wire connector to cargo lamp unit.
(4) Place cargo lamp unit into opening and apply hand pressure to seat lamp unit into rear quarter panel.
(5) Install jack and tool bag in the storage area.
(6) Install jack storage door to the right rear quarter trim panel.
(7) Close liftgate.

REAR CARGO LAMP UNIT

REMOVAL

(1) Open liftgate.
(2) Remove jack storage door from right rear quarter trim panel.
(3) Remove jack and tool bag.
(4) Place right hand on stem of cargo lamp unit and pull downward until lens separates from the cargo lamp unit (Fig. 7).
(5) Pull cargo lamp unit through jack storage door opening to access bulb.
(6) Disconnect wire connector from cargo lamp unit.
(7) Remove cargo lamp unit from vehicle.

INSTALLATION

(1) Snap lens onto lamp unit (Fig. 7).
(2) Move wire connector through lamp opening and connect wire connector to cargo lamp unit.
(3) Place cargo lamp unit into opening and apply hand pressure to seat lamp unit into rear quarter panel.
(4) Install jack and tool bag in the storage area.
(5) Install jack storage door to the right rear quarter trim panel.
(6) Close liftgate.

TRANS RANGE INDICATOR ILLUMINATION

REMOVAL

(1) Remove gear shift knob.
(2) Remove floor console.
(3) Disconnect socket from transaxle range indicator (Fig. 8).
(4) Remove bulb from socket.

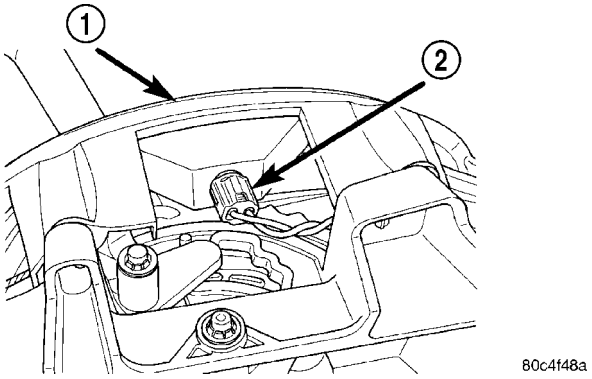

Fig. 8 TRANSMISSION RANGE INDICATOR

1 - TRANSMISSION RANGE INDICATOR
2 - TRANSMISSION RANGE INDICATOR LAMP BULB AND SOCKET

INSTALLATION

(1) Push bulb into socket (Fig. 8).
(2) Snap socket into position.
(3) Install floor console into position.
(4) Install gear shift knob.

VANITY LAMP

REMOVAL

(1) Lower visor.
(2) Insert a small flat bladed tool into the slot between the lamp lens and lamp.
(3) Carefully pry lens outward.
(4) Remove bulb from socket.

INSTALLATION

(1) Position bulb in socket and push into place.
(2) Position lens on lamp and snap into place.

UNIVERSAL TRANSMITTER
DESCRIPTION 1
OPERATION 1
DIAGNOSIS AND TESTING
UNIVERSAL TRANSMITTER 2
STANDARD PROCEDURE
ERASING TRANSMITTER CODES 2
SETTING TRANSMITTER CODES 2
REMOVAL 2
INSTALLATION 2

UNIVERSAL TRANSMITTER

DESCRIPTION

Some vehicles are equipped with a Universal Transmitter transceiver. The universal transmitter transceiver is located in the drivers side sun visor assembly. The only visible component of the universal transmitter are the three transmitter push buttons. The three universal transmitter push buttons are identified with raised buttons and light indicators so that they can be easily identified by sight or by feel (Fig. 1).

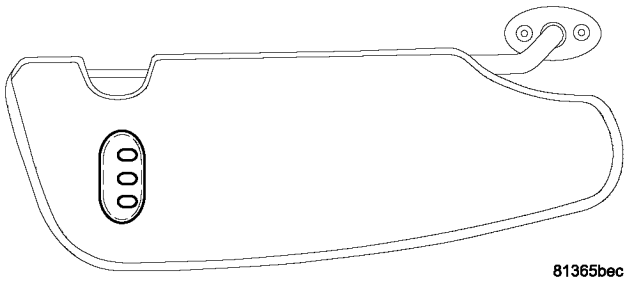

Fig. 1 VISOR WITH UNIVERSAL TRANSMITTER

Each of the three universal transmitter push buttons controls an independent radio transmitter channel. Each of these three channels can be trained to transmit a different radio frequency signal for the remote operation of garage door openers, motorized gate openers, home or office lighting, security systems or just about any other device that can be equipped with a radio receiver in the 286 to 399 MegaHertz (MHz) frequency range for remote operation. The universal transmitter is capable of operating systems using either rolling code or non-rolling code technology. The system will not transmit operating signals if the Vehicle Theft Security System is armed.

The universal transmitter cannot be repaired, and is available for service only as a visor assembly. If any part of the component is inoperative or damaged, the complete visor assembly must be replaced.

OPERATION

The universal transmitter operates on a non-switched source of battery current so the unit will remain functional, regardless of the ignition switch position. For more information on the features, programming procedures and operation of the universal transmitter, see the owner's manual in the vehicle glove box.

UNIVERSAL TRANSMITTER (Continued)

DIAGNOSIS AND TESTING

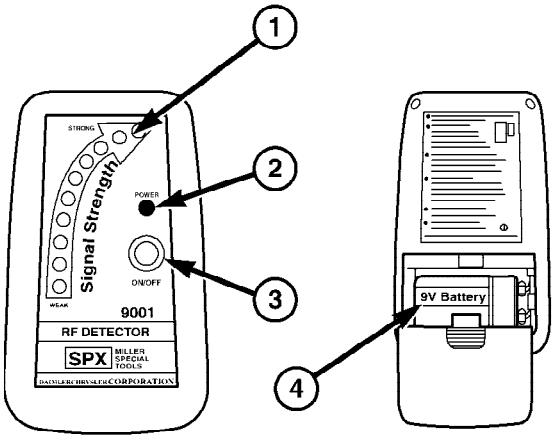
UNIVERSAL TRANSMITTER

If the Universal Transmitter is inoperative, retrain the universal transmitter with a known good transmitter, (Refer to 8 - ELECTRICAL/MESSAGE CENTER/UNIVERSAL TRANSMITTER - STANDARD PROCEDURE) for the proper procedure. Test the universal transmitter operation again. If the unit is still inoperative, test the universal transmitter with Radio Frequency Detector special tool (Fig. 2) as described below:

(1) Turn the Radio Frequency (RF) Detector ON. A “chirp” will sound and the green power LED will light. If the green LED does not light, replace the battery.

(2) Hold the RF detector within one inch of the TRAINED universal transmitter and press any of the transmitters buttons.

(3) The red signal detection LEDs will light and the tool will beep if a radio signal is detected. Repeat this test for all three transmitter buttons. If the tool does not detect a radio signal for any of the three buttons, replace the inoperative universal transmitter assembly, (Refer to 23 - BODY/INTERIOR/SUN VISOR - REMOVAL).



80f230cb

Fig. 2 RADIO FREQUENCY DETECTOR

1 - SIGNAL DETECTION LED’S
2 - POWER LED
3 - ON/OFF SWITCH
4 - 9V BATTERY

STANDARD PROCEDURE

ERASING TRANSMITTER CODES

To erase the universal transmitter codes, simply hold down the two outside buttons labeled with one (·) and three (···) dots until the display confirms the operation.

NOTE: Individual channels cannot be erased. Erasing the transmitter codes will erase ALL programmed codes.

SETTING TRANSMITTER CODES

(1) Turn off the engine.

(2) Erase the codes by pressing the two outside buttons labeled with one (·) and three (···) dots. Release the buttons when the display confirms the operation (about 20 seconds).

(3) Choose one of the three buttons to train. Place the hand-held transmitter within one inch of the universal transmitter and push the buttons on both transmitters.

(4) Release both buttons. Your universal transmitter is now “trained”. To train the other buttons, repeat Step 3 and Step 4. Be sure to keep your hand-held transmitter in case you need to retrain the universal transmitter.

REMOVAL

(1) (Refer to 23 - BODY/INTERIOR/SUN VISOR - REMOVAL), for universal transmitter removal.

INSTALLATION

(1) (Refer to 23 - BODY/INTERIOR/SUN VISOR - INSTALLATION), for universal transmitter installation.

OVERHEAD CONSOLE

DESCRIPTION

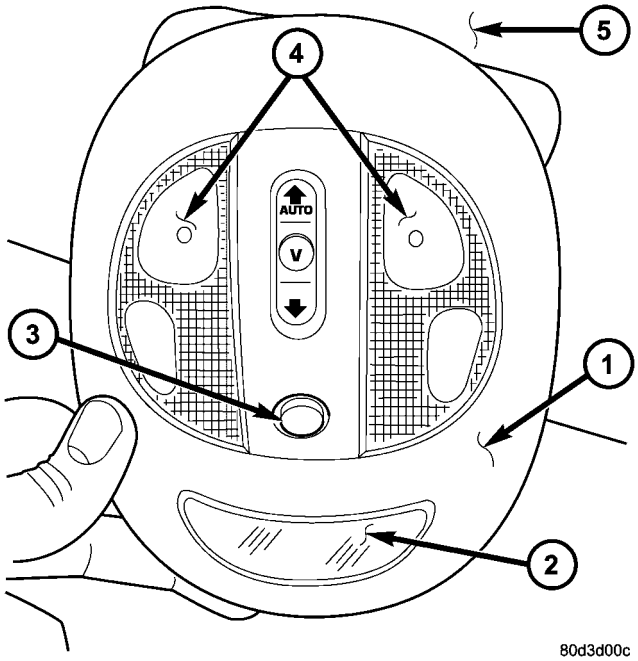

Fig. 1 PT Overhead Console

1 - OVERHEAD CONSOLE HOUSING
2 - DISPLAY SCREEN
3 - DISPLAY STEP BUTTON
4 - READING/COURTESY LAMPS
5 - HEADLINER

The overhead console includes the Compass/Temperature read-out and two reading and courtesy lamps. This display provides the outside temperature and one of eight compass readings to indicate the direction the vehicle is facing. The outside temperature is monitored by the ambient temperature sensor mounted on the support brace in front of the A/C condenser, behind the front grille. The ambient temperature is hardwired directly to the overhead console. On vehicles equipped with a power sunroof option, the overhead console also houses the power sunroof switch between the two reading and courtesy lamps (Fig. 1). The overhead console is snapped into place near the front of the vehicle's roof and clips on the headliner, at the rear of the overhead console. There is a STEP button for the compass/temperature read-out located forward of the sunroof switch (if equipped), and between the map/reading/courtesy lamps.

The overhead console is equipped with two individual reading and courtesy lamps. The lamp lenses are the only visible components of these lamps. The reading and courtesy lamp lenses are mounted near the rear of the overhead console housing. Each lamp has its own switch, bulb and lens; but both lamps share a common lamp housing within the overhead console. Each lamp is designed and aimed to provide illumination that will be directed only to that side of the vehicle on which the lamp is located.

The reading and courtesy lamp lenses and the lamp housing unit are serviced only as a unit with the overhead console housing. If either of the lamp lenses or the lamp housing is faulty or damaged, the overhead console housing unit must be replaced.

OPERATION

There is a STEP button to display the compass/temperature, and can be read in either F° or C°. When the vehicle is first turned ON, you may select to have the overhead console:

- Blank display
- Compass/Temperature displayed in Fahrenheit
- Compass/Temperature displayed in Celsius

To put the compass/temperature in the F° display, press the STEP button once. To put the compass/temperature in the C° display, press the STEP button

OVERHEAD CONSOLE (Continued)

twice. A third press of the STEP button will return it to the blank display.

The overhead console reading and courtesy lamps operate on battery current that is provided at all times, regardless of the ignition switch position. The ground feed for the lamps is switched through the integral reading and courtesy lamp switches or through the door jamb switches.

All reading and courtesy lamps located in the overhead console are activated by the door jamb switches. When all of the doors are closed, these lamps can be individually activated by depressing the corresponding lens. When any door is open, depressing the lamp lenses to activate the lamp switches will not turn the lamps off.

Each light is turned ON by pressing the lens. Press the lens a second time to turn the light OFF. The lights also come ON when a door is opened or the dimmer switch is turned fully upward, past the second detent.

NOTE: The lights will remain ON until the switch is pressed a second time, so be sure they have been turned OFF before leaving the vehicle. They will not turn OFF automatically.

AUTOMATIC COMPASS CALIBRATION

The self calibrating feature of the compass eliminates the need to calibrate the compass for normal conditions. After approximately 10 ignition cycles the CAL light will turn ON. The CAL symbol may also appear after the vehicle is subjected to a high level of magnetism. After completing three 360° (degree) circles in an area free from large metal or metallic objects, the CAL symbol will turn off and the compass will function normally.

MANUAL COMPASS CALIBRATION

If the compass appears to be in the locked up position, you may calibrate the compass. Find an open area away from large metal objects. With the ignition OFF, press and hold the STEP button while turning ON the ignition. Release the STEP button and the CAL light will appear (about 10-15 seconds). Drive in 3 complete 360° (degree) circles. The CAL light will turn off and the compass will be calibrated.

ZONE VARIANCE

Compass variance, also known as magnetic declination, is the difference in angle between magnetic north and true geographic north. In some geographic locations, the difference between magnetic and geographic north is great enough to cause the compass to give false readings. For proper compass function, the correct variance zone must be set. Refer to the variance map for the correct variance zone in your area. To check the variance zone, the ignition switch must be ON and the compass/temperature displayed. Press and hold the STEP button for about 5-15 seconds until ZONE appears in the display, then release the button. The number displayed is the variance zone set in the compass. To change the zone refer to the standard procedure later in this section.

OUTSIDE TEMPERATURE

Since the ambient temperature sensor is in close proximity to the radiator, it can pick up engine heat giving a false “high” outside air temperature reading - known as “Heat Soak”. In order to display a more correct outside temperature, the overhead console will not increase the displayed temperature until it detects movement in the compass over a two-minute period, to insure that there is adequate airflow over the sensor. “Movement over a two minute period” is best understood as once in the first minute, then some more detected movement in the second minute.

If the display shows an open circuit OC (or -49° F (-45° C) then there is an OPEN CIRCUIT or a missing sensor and the condition must be corrected. Keep in mind that after a repair is made, the vehicle may need to be driven to update the temperature for the reasons described above. Even if the engine is cool, it will not increase from -49°F without detecting movement.

STANDARD PROCEDURE

COMPASS CALIBRATION

CAUTION: Do not place any external magnets, such as magnetic roof mount antennas, in the vicinity of the compass. Do not use magnetic tools when servicing the overhead console.

The electronic compass features a self-calibrating design, which simplifies the calibration procedure. This feature automatically updates the compass calibration while the vehicle is being driven. This allows the compass unit to compensate for small changes in the residual magnetism that the vehicle may acquire during normal use. If the compass readings appear to be erratic or out of calibration, perform the following calibration procedure. Also, new service replacement compass mini-trip computer modules must have their compass calibrated using this procedure. Do not attempt to calibrate the compass near large metal objects such as other vehicles, large buildings, or bridges; or, near overhead or underground power lines.

(1) Start the engine. If the compass/temperature data is not currently being displayed, momentarily depress and release the Step push button (this unla-

OVERHEAD CONSOLE (Continued)

beled button is located directly behind the overhead console display screen) to step through the display options until you have reached the compass/temperature display.

(2) Depress the Step push button, until “ZONE” appears in the display (approx. 5-10 seconds), then “CAL” will be displayed. Release the Step button when CAL is displayed. The “CAL” in the display indicates that the compass is in the calibration mode.

(3) Drive the vehicle on a level surface, at least fifty feet away from large metal objects and power lines, in all four compass directions, such as driving around a city block several times or driving in two to three complete circles at a slow speed (approx. 5 mph) until the CAL is no longer displayed.

(4) Finally, set the proper zone/variance for the area you are in, when in manual override mode for calibration, it defaults to zone 8.

NOTE: If the “CAL” message remains in the display, either there is excessive magnetism near the compass, or the unit is faulty. Repeat the calibration procedure at least one more time.

NOTE: If the wrong direction is still indicated in the compass display, the area selected for calibration may be too close to a strong magnetic field. Repeat the calibration procedure in another location.

COMPASS VARIATION ADJUSTMENT

Compass variance, also known as magnetic declination, is the difference in angle between magnetic north and true geographic north. In some geographic locations, the difference between magnetic and geographic north is great enough to cause the compass to give false readings.

If a customer moves, or drives across zones the compass variation will have to be reprogrammed so that the compass will display the correct readings. If problems like these occur, the compass variance must be set. Use the following procedure to program the compass zone variation.

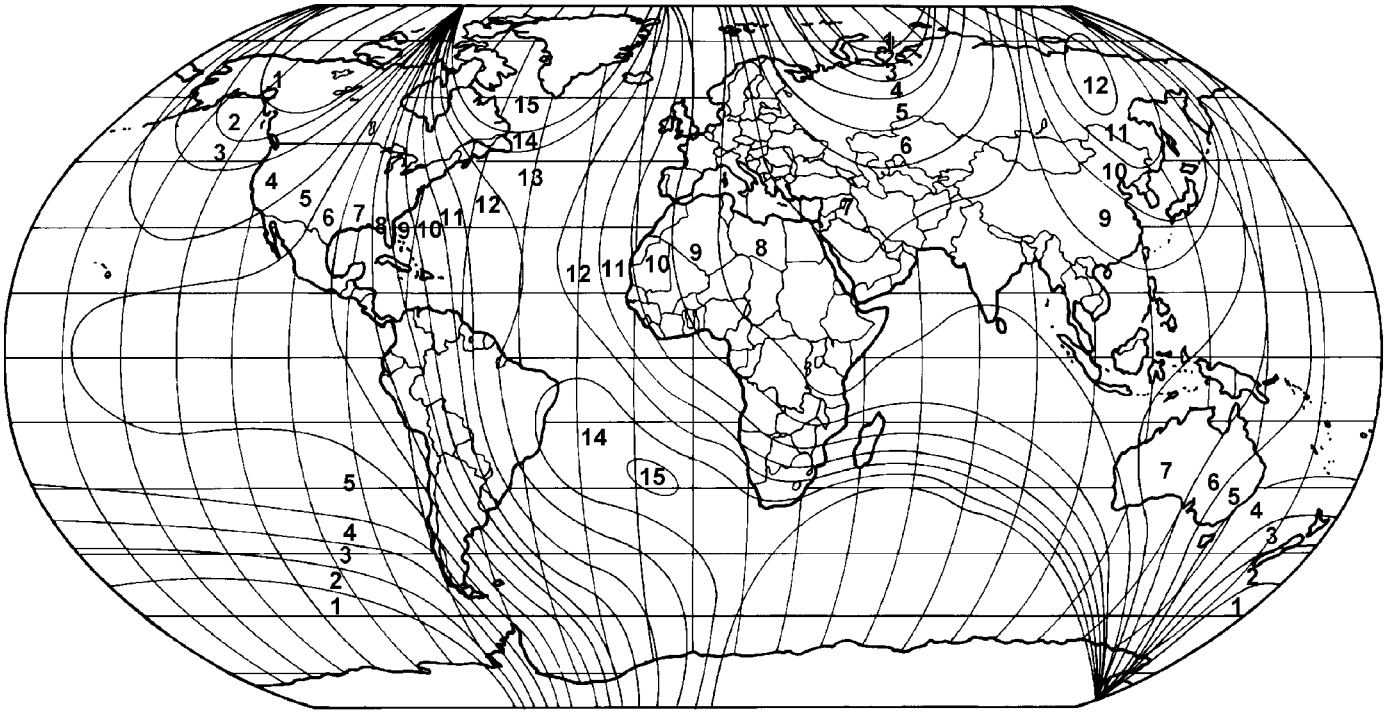
PROGRAMMING ZONE VARIATION

(1) Using the Variance Zone map, find your geographic location and note the zone number (Fig. 2).

(2) Turn the ignition switch to the On position. If the compass/temperature data is not currently being displayed, momentarily depress and release the Step push button to step through the display options until you have reached the compass/temperature display.

(3) Depress the Step push button and hold down until the compass mini-trip computer enters the variation adjustment mode and “VAR” along with the current variance zone will appear in the display.

(4) Momentarily depress and release the Step push button to step through the zone numbers, until the zone number for your geographic location appears in the display.



80a13863

Fig. 2 Variance Zones

OVERHEAD CONSOLE (Continued)

(5) After five seconds, the displayed zone will automatically be set in the compass mini-trip computer module memory and normal operation will resume.

(6) Confirm that the correct directions are now indicated by the compass.

COMPASS DEMAGNETIZING

A degaussing tool (Special Tool 6029) is used to demagnetize, or degauss, the overhead console forward mounting screw and the roof panel above the overhead console. Equivalent units must be rated as continuous duty for 110/115 volts and 60 Hz. They must also have a field strength of over 350 gauss at 7 millimeters (0.25 inch) beyond the tip of the probe.

To demagnetize the roof panel and the overhead console forward mounting screw, proceed as follows:

(1) Be certain that the ignition switch is in the Off position, before you begin the demagnetizing procedure.

(2) Connect the degaussing tool (Fig. 3)to an electrical outlet, while keeping the tool at least 61 centimeters (2 feet) away from the compass unit.

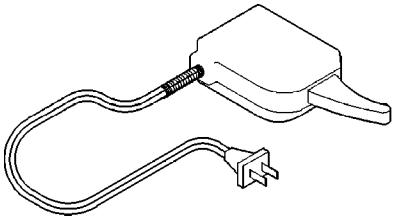


Fig. 3 Degaussing Tool 6029

(3) Slowly approach the head of the overhead console forward mounting screw with the degaussing tool connected.

(4) Contact the head of the screw with the plastic coated tip of the degaussing tool for about two seconds.

(5) With the degaussing tool still energized, slowly back it away from the screw. When the tip of the tool is at least 61 centimeters (2 feet) from the screw head, disconnect the tool.

(6) Place a piece of paper approximately 22 by 28 centimeters (8.5 by 11 inches), oriented on the vehicle lengthwise from front to rear, on the center line of the roof at the windshield header (Fig. 4). The purpose of the paper is to protect the roof panel from scratches, and to define the area to be demagnetized.

(7) Connect the degaussing tool to an electrical outlet, while keeping the tool at least 61 centimeters (2 feet) away from the compass unit.

(8) Slowly approach the center line of the roof panel at the windshield header, with the degaussing tool connected.

(9) Contact the roof panel with the plastic coated tip of the degaussing tool. Be sure that the template is in place to avoid scratching the roof panel. Using a slow, back-and-forth sweeping motion, and allowing 13 millimeters (0.50 inch) between passes, move the tool at least 11 centimeters (4 inches) to each side of the roof center line, and 28 centimeters (11 inches) back from the windshield header.

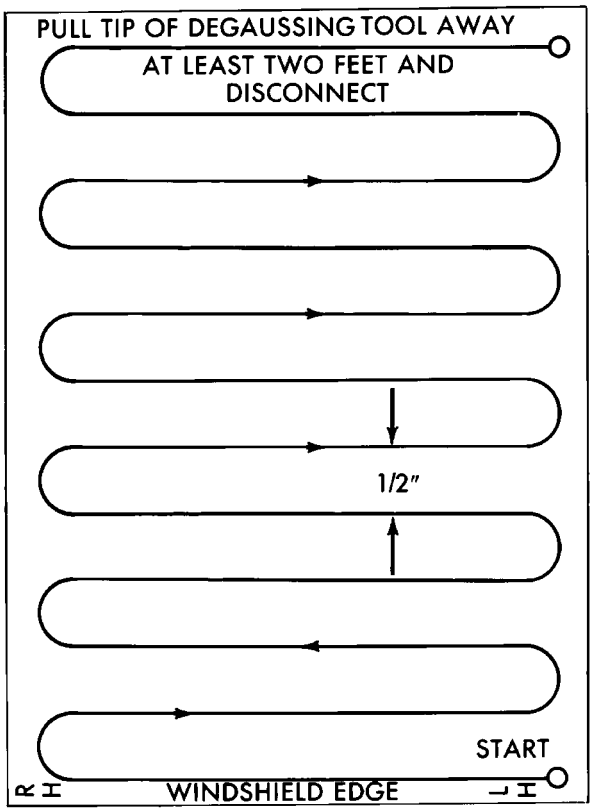

Fig. 4 Roof Demagnetizing Pattern

(10) With the degaussing tool still energized, slowly back it away from the roof panel. When the tip of the tool is at least 61 centimeters (2 feet) from the roof panel, disconnect the tool.

(11) Calibrate the compass and adjust the compass variance. Refer to **Compass Variation Adjustment** and **Compass Calibration** in this section for the procedures.

REMOVAL

(1) Disconnect and isolate the negative battery cable.

(2) Grasp the front of the overhead console and pull downward to disconnect the front retaining clips.

(3) Slide the overhead console forward to disengage the rear tabs from the headliner.

(4) Disconnect the overhead console wire connector.

(5) Unsnap compass module from inner roof panel. Push module all the way forward to disengage the front retaining clip. Once the front clip is disconnected, push the module all the way rearward to disengage the rear retaining clip.

OVERHEAD CONSOLE (Continued)

(6) Remove console from vehicle.

INSTALLATION

(1) Position overhead console into vehicle and snap compass module onto inner roof panel.

(2) Connect overhead console wire harness connector.

(3) Engage the rear tabs on the overhead console into the headliner.

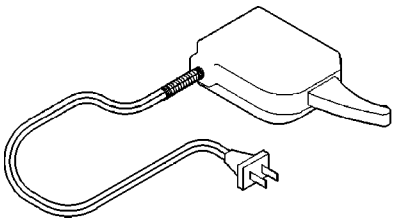
(4) Align the front retaining clips of the overhead console with the corresponding holes in the inner roof panel and firmly snap into place.

(5) Connect the battery negative cable.

(6) Calibrate compass (Refer to 8 - ELECTRICAL/ OVERHEAD CONSOLE - STANDARD PROCEDURE).

SPECIAL TOOLS

OVERHEAD CONSOLE



Degaussing Tool 6029

AMBIENT TEMP SENSOR

DESCRIPTION

Ambient air temperature is monitored by the compass/temperature display unit. It receives a hard wired input from the ambient temperature sensor. The ambient temperature sensor is a variable resistor mounted to a bracket that is secured with a nut to the bracket in front of the A/C condenser, behind the radiator grille.

The ambient temperature sensor cannot be adjusted or repaired and, if faulty or damaged, it must be replaced.

OPERATION

The ambient temperature sensor is a variable resistor that operates on a five-volt reference signal. The resistance in the sensor changes as temperature changes, changing the temperature sensor signal circuit voltage to compass/temperature display unit. Based upon the resistance in the sensor, the compass/temperature display unit senses a specific voltage on the temperature sensor signal circuit, which it is programmed to correspond to a specific temperature. The compass/temperature display unit then displays the proper ambient temperature.

DIAGNOSIS AND TESTING

AMBIENT TEMPERATURE SENSOR

The thermometer function is supported by the ambient temperature sensor, a wiring circuit, and the compass/temperature display unit.

If the display shows OC (-49° F (-45° C) or SC (140° F (60° C),, there is an OPEN or SHORT CIRCUIT and it must be repaired before the VFD can be tested.

The ambient temperature sensor circuit can also be diagnosed using the following Sensor Test, and Sensor Circuit Test. If the temperature sensor and circuit are confirmed to be OK, but the temperature display is inoperative or incorrect, replace the compass/temperature display.

SENSOR TESTING

(1) Turn the ignition switch to the OFF position. Disconnect and isolate the battery negative cable (Fig. 5). Disconnect the ambient temperature sensor wire harness connector.

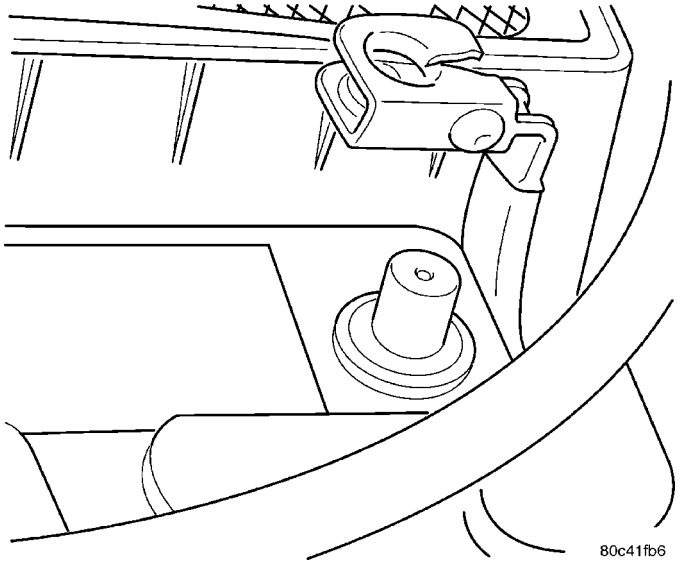


Fig. 5 Battery Negative Cable Remove/Install

(2) Measure the resistance of the ambient temperature sensor. At room temperature (approx. 68°F), the sensor resistance should be between 9-11 Kilohms (9000-11000 ohms). The sensor resistance should read between these two values. If OK, refer to Sensor Circuit Testing below. If not OK, replace the faulty ambient temperature sensor.

SENSOR CIRCUIT TESTING

(1) Turn the ignition switch to the OFF position. Disconnect and isolate the battery negative cable. Disconnect the ambient temperature sensor wire harness connector and the compass/temperature display unit wire harness connector.

AMBIENT TEMP SENSOR (Continued)

(2) Connect a jumper wire between the two terminals in the body half of the ambient temperature sensor wire harness connector.

(3) Check for continuity between the sensor return circuit and the ambient temperature sensor signal circuit cavities of the compass/temperature display unit wire harness connector. There should be continuity. If OK, go to Step 4. If not OK, repair the open sensor return circuit or ambient temperature sensor signal circuit to the ambient temperature sensor as required.

(4) Remove the jumper wire from the body half of the ambient temperature sensor wire harness connector. Check for continuity between the sensor return circuit cavity of the compass/temperature display unit wire harness connector and a good ground. There should be no continuity. If OK, go to Step 5. If not OK, repair the shorted sensor return circuit as required.

(5) Check for continuity between the ambient temperature sensor signal circuit cavity of the compass/temperature display unit wire harness connector and a good ground. There should be no continuity. If OK, replace the compass/temperature display unit. If not OK, repair the shorted ambient temperature sensor signal circuit as required.

REMOVAL

(1) Open hood.

(2) Working through the hole in the top center of the grille, remove the one retaining nut from the appropriate ambient temperature sensor (Fig. 6).

(3) Disconnect the ambient air temperature sensor electrical connector and remove the sensor from the vehicle.

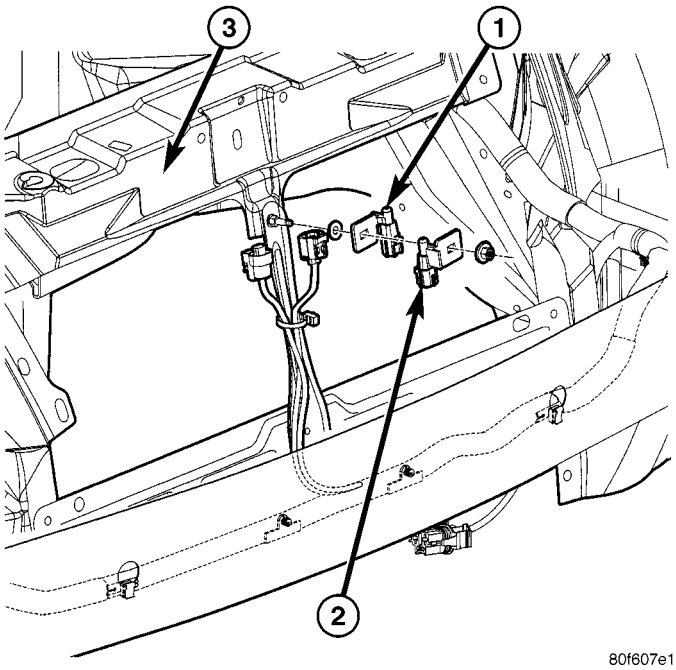

Fig. 6 AMBIENT AIR TEMPERATURE SENSOR LOCATION

1 - Air Temperature Sensor - NGC Engine Controller
2 - Air Temperature Sensor - Overhead Console
3 - Radiator Closure Panel

INSTALLATION

(1) Install the one retaining nut to ambient temperature sensor.

(2) Connect the battery negative cable.

(3) Close hood.

POWER LOCKS

DESCRIPTION

POWER LOCKS

The power lock system allows all of the doors and the liftgate to be locked or unlocked electrically by operating a switch on either front door trim panel. The power lock system receives non-switched battery current through a fuse in the Fuse Block, so that the power locks remain operational, regardless of the ignition switch position.

This vehicle also offers several customer programmable features, which allows the selection of several optional electronic features to suit individual preferences.

The power lock system for this vehicle can also be operated remotely using the available Remote Keyless Entry (RKE) system Radio Frequency (RF) transmitters, if equipped.

Certain functions and features of the power lock system rely upon resources shared with other electronic modules in the vehicle over the Programmable Communications Interface (PCI) data bus network. For proper diagnosis of these electronic modules or of

the PCI data bus network, the use of a DRBIII® scan tool and the appropriate diagnostic information are required.

CHILD PROTECTION LOCKS

To provide a safer environment for children riding in the rear seat, the rear doors have the “child protection” door lock system.

The child protection locks are on the rear doors only. The lock, when engaged, will disable the inside door handle from opening the door. The lock is part of the latch/lock assembly.

DOOR LOCK INHIBIT

With the key in the ignition switch and the driver door open, the Remote Keyless Entry (RKE) module will ignore the command to lock the power door locks using the interior door lock switches. Once the key is removed, or the drivers door is closed, the RKE module will allow the power locks to lock using the door lock switch.

REMOTE KEYLESS ENTRY

The remote keyless entry system allows locking and unlocking of the vehicle door(s) liftgate, panic alarm and arming or disarming of the vehicle theft security system (if equipped), using the hand held (RF) transmitter.

The RKE module is also referred to as the Alarm Remote Keyless Entry Module (ARKEM). It also contains the functionality for the Vehicle Theft Security System (VTSS).

The module may receive signals from up to four transmitters. Each transmitter has its own code, and the code is programmed and stored into the module memory. If a transmitter is replaced or additional transmitters are added, the codes for all units have to be reprogrammed into the RKE module or ARKEM memory. If a module is replaced, the transmitter codes must be stored in the new memory (by performing the steps for programming transmitters). The RKE or ARKEM is capable of retaining all transmitter codes when power is removed from the module.

OPERATION

POWER LOCKS

All doors can be locked or unlocked mechanically and independently with their respective locking knobs. The front doors can also be unlocked by actuation of the inside remote door handle.

CENTRAL LOCKING/UNLOCKING (IF EQUIPPED)

The door locks can be locked or unlocked electrically via the exterior door key cylinders to provide the central locking/unlocking feature. The central locking/unlocking feature incorporates a customer programmable ″Double activation unlock″ feature which operates in the following manner: When enabled, the first turn of the key cylinder to the UNLOCK position (toward the front of the vehicle) will mechanically unlock the door whose key cylinder is being turned. A second turn of the key cylinder to the UNLOCK position (within five seconds of the first turn) will cause all vehicle doors and liftgate to unlock electrically. When this feature is disabled, all vehicle doors and liftgate will be unlocked electrically upon the first turn of a key cylinder to the UNLOCK position. The vehicle is locked electrically by turning the key cylinder to the LOCK position once, regardless of the state of the double activation unlock feature.

REMOTE KEYLESS ENTRY

The transmitter has three buttons for operation: LOCK, UNLOCK and PANIC.

- Pressing the UNLOCK button will unlock the driver’s door, flash the park lamps twice and enable illuminated entry. Pressing and releasing the button once will unlock the drivers door. Pressing and releasing the button two tomes within a five second interval will unlock all doors.
- Pressing the LOCK button will cause the horn to sound a short chirp (if enabled) and flash the park lamps to notify that the all door lock signal was received and set. Illuminated entry is cancelled and the interior lamps are faded to off.
- Pressing the PANIC button will cause the panic alarm to sound for three minutes, until the PANIC button is pressed a second time, or the vehicle reaches a speed of 25.7 Km/h (15 mph). The receiver is capable of retaining a Vehicle Access Code (VAC) even when power is removed. Each Remote Keyless Entry (RKE) module must have at least one and no more than four transmitter.

ROLLING DOOR LOCKS

When the rolling door lock system is enabled, the RKE module will automatically lock all the vehicle doors and liftgate when all of the following conditions are met:

- All doors are closed
- The vehicle speed exceeds 25.7 Km/h (15 +/- 1 mph).
- The throttle position sensor tip-in is greater than 10 +/- 2 degrees.

The RKE module will automatically re-lock all doors if the above conditions are met and if any of the doors become ajar and then closed again.

POWER LOCKS (Continued)

The enabling/disabling of the rolling door lock feature is customer programmable, as well as programmable with the DRB lll® scan tool.

The power lock motors are also equipped with a thermal protection system which prevents the motors from burning out. The motors may chatter if they are continuously activated.

DIAGNOSIS AND TESTING - POWER LOCKS

The most reliable, efficient, and accurate means to diagnose the power lock system requires the use of a DRBIII® scan tool and the proper Diagnostic Procedures manual. The DRBIII® scan tool can provide confirmation that the PCI data bus is functional, that all of the electronic modules are sending and receiving the proper messages on the PCI data bus, and that the power lock motors are being sent the proper hard wired outputs by the relays for them to perform their power lock system functions.

STANDARD PROCEDURE

STANDARD PROCEDURE - DOUBLE ACTIVATION UNLOCK

The toggling of the double activation unlock feature (between enabled and disabled) can be performed with the use of the DRB lll® scan tool, or by the customer.

DRB III® PROGRAMMING

When using the DRB lll® scan tool, select:
(1) “Theft Alarm”
(2) “VTSS”
(3) “Miscellaneous”
and then the desired function.

CUSTOMER PROGRAMMING

(1) Open the driver door, sit in the driver seat, and close the driver door.

(2) Turn the ignition switch to the RUN position (without starting the vehicle) and then back to OFF. Repeat this step three additional times (for a total of four key ON/OFF cycles).

(3) Within ten seconds of switching the ignition switch to the OFF position for the last time (at the end of the fourth cycle in the above step), press the driver interior door lock switch to UNLOCK.

(4) A single chime will be heard to verify that the customer programmable toggle of the double activation unlock was successfully completed.

Steps 2 and 3 must be completed within 10 seconds.

NOTE: When toggling the double activation unlock feature (customer programmable), the toggle that happens will be from the last state of the double activation unlock. If the double activation unlock feature was enabled, after the toggle process, it will now be disabled and vice versa. There is no telltale to inform you of which state the double activation unlock feature is in.

STANDARD PROCEDURE - ROLLING DOOR LOCKS

The toggling of the rolling door lock feature (between enabled and disabled) can be performed with the use of the DRB lll® scan tool or by the customer.

DRB III® PROGRAMMING

When using the DRB lll® scan tool, select:
(1) “Theft Alarm”
(2) “VTSS”
(3) “Miscellaneous”
and then the desired function.

CUSTOMER PROGRAMMING

(1) Open the driver door, sit in the driver seat, and close the driver door.

(2) Turn the ignition switch to the RUN position (without starting the vehicle) and then back to OFF. Repeat this step three additional times (for a total of four key ON/OFF cycles).

(3) Within ten seconds of switching the ignition switch to the OFF position for the last time (at the end of the fourth cycle in the above step), press the driver interior door lock switch to LOCK.

(4) A single chime will be heard to verify that the customer programmable toggle of the rolling door locks was successfully completed.

Steps 2 and 3 must be completed within 10 seconds.

NOTE: When toggling the rolling door locks (customer programmable), the toggle that happens will be from the last state of the rolling door locks. If the rolling door locks were enabled, after the toggle process, they will now be disabled and vice versa. There is no telltale to inform you of which state the rolling door locks are in.

DOOR LOCK SWITCH

DIAGNOSIS AND TESTING - DOOR LOCK SWITCH

(1) Remove the switch.

(2) Using an ohmmeter, refer to Door Lock Switch Test table to determine if switch resistance is correct in the Lock and Unlock switch positions. Refer to Wiring Diagrams for harness connector pin-outs.

DOOR LOCK SWITCH (Continued)

DOOR LOCK SWITCH TEST

SWITCH POSITION	PINS	RESISTANCE VALUE
LOCK	2 AND 3	1K OHM ±10 %
UNLOCK	2 AND 3	249 OHM ± 10 %

REMOVAL

(1) Disconnect and isolate the battery negative cable.

(2) Remove front door trim panel (Refer to 23 - BODY/DOOR - FRONT/TRIM PANEL - REMOVAL).

(3) Disconnect wire connector to door lock switch.

(4) Remove two attaching screws to switch.

(5) Remove the switch from trim panel.

INSTALLATION

(1) Install the switch on trim panel.

(2) Install two attaching screws to switch.

(3) Connect wire connector to door lock switch.

(4) Install front door trim panel (Refer to 23 - BODY/DOOR - FRONT/TRIM PANEL - INSTALLATION).

(5) Connect the battery negative cable.

DOOR LOCK MOTOR

DESCRIPTION

The lock mechanisms are actuated by a reversible electric motor mounted within each door and tailgate. The power lock motors are integral to the door latch units.

The power lock motors cannot be adjusted or repaired and, if faulty or damaged, the door latch unit must be replaced.

OPERATION

The door lock motors are controlled by relays. A positive and negative battery connection to the two motor terminals will cause the motor to move in one direction. Reversing the current will cause the motor to move in the opposite direction.

DIAGNOSIS AND TESTING - DOOR LOCK MOTOR

The most reliable, efficient, and accurate means to diagnose the power lock system requires the use of a DRBIII® scan tool and the proper Diagnostic Procedures manual.

Refer to the appropriate wiring information.

(1) Make certain battery is in normal condition and fuses powering the RKE module aren't blown before circuits are tested.

(2) To determine which motor is faulty, check each individual door for electrical lock and unlock or disconnect the motor connectors one at a time, while operating the door lock switch.

(3) In the event that none of the motors work, the problem maybe caused by a shorted motor, a bad switch or a bad relay internal to the RKE module. Disconnecting a defective motor will allow the others to work.

(4) To test an individual door lock motor, disconnect the electrical connector from the motor.

(5) To lock the door, connect a 12 volt power source to one pin of the lock motor and a ground wire to the other pin.

(6) To unlock the door, reverse the wire connections at the motor pin terminals.

(7) If these results are NOT obtained, replace the motor.

LIFTGATE LOCK MOTOR

REMOVAL

(1) Disconnect and isolate the battery negative cable.

(2) Remove liftgate trim panel.

(3) Disconnect motor wire harness connector.

(4) Remove liftgate lock motor from liftgate (Fig. 1) by gently unsnapping.

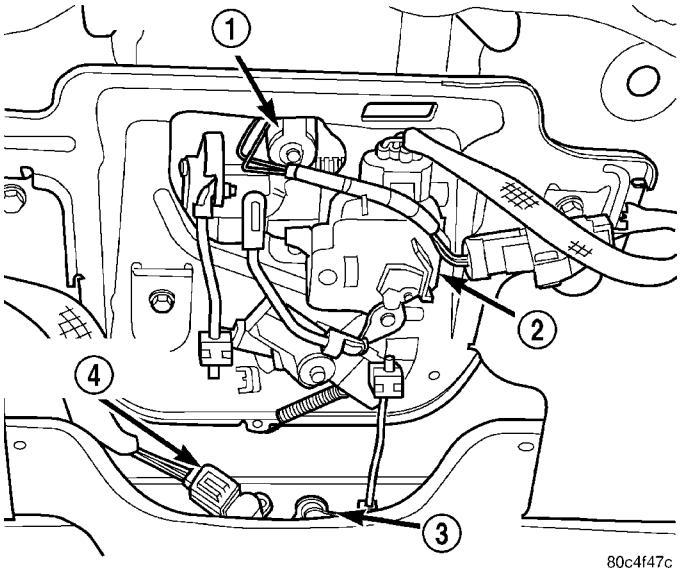

Fig. 1 LIFTGATE LOCK MOTOR

1 - LIFTGATE CYLINDER LOCK SWITCH
2 - LIFTGATE LOCK MOTOR
3 - LATCH ASSEMBLY
4 - LIFTGATE AJAR SWITCH

INSTALLATION

(1) Install liftgate lock motor on the liftgate.

(2) Install motor wire harness connector.

(3) Install the liftgate trim panel.

(4) Connect the battery negative cable.

REMOTE KEYLESS ENTRY MODULE

DIAGNOSIS AND TESTING - REMOTE KEYLESS ENTRY MODULE

The most reliable, efficient, and accurate means to diagnose the power lock system requires the use of a DRBIII® scan tool and the proper Diagnostic Procedures manual.

Refer to the appropriate wiring information.

REMOVAL

(1) Disconnect and isolate the battery negative cable.

(2) Remove the instrument panel top cover.

(3) Remove the two screws holding the RKE module to the instrument panel assembly (Fig. 2).

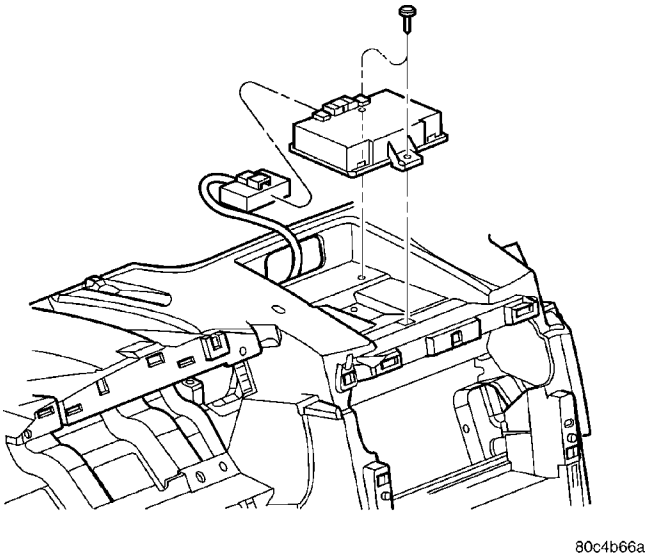

Fig. 2 RKE MODULE

(4) Slide locking tab of the wiring connector sideways to unlock tab, and remove connector from RKE module.

(5) Remove RKE module from vehicle.

NOTE: When replacing a faulty RKE Module, the replacement module must be configured with the DRB III® scan tool for proper operation. Refer to Vehicle Theft/Security Systems, Configuring a New Module under Service Procedures. Additionally, all transmitters must be reprogrammed to the new RKE module.

INSTALLATION

(1) Install the RKE module on instrument panel.

(2) Connect the wiring harness connector to the RKE module. Slide locking tab of the wiring connector sideways to lock tab.

(3) Install the two screws holding the RKE module to the instrument panel assembly.

(4) Install the instrument panel top cover.

(5) Connect the battery negative cable.

REMOTE KEYLESS ENTRY TRANSMITTER

DESCRIPTION

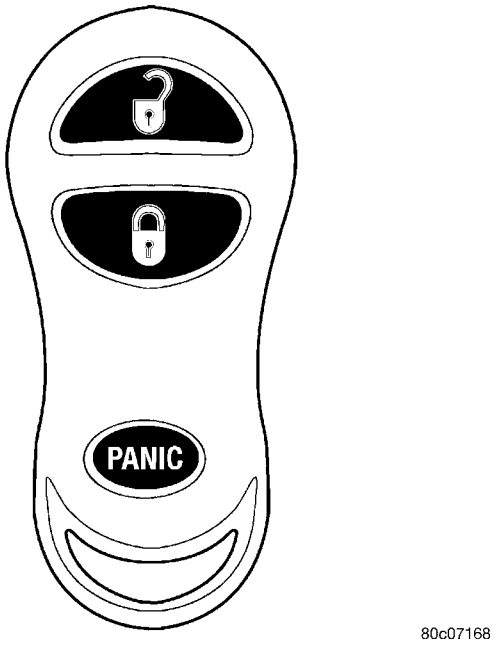

Fig. 3 Remote Keyless Entry (Key Fob) Transmitter

The transmitter has three buttons for operation (Fig. 3). They are **LOCK**, **UNLOCK**, and **PANIC**.

OPERATION

- The **UNLOCK** button will unlock the driver door flash the Park lamps twice and enable illuminated entry. Pushing and releasing the button once will unlock the driver door. Pushing and releasing the button two times within a five second period will unlock all doors (double unlock activation enabled).
- Upon pressing the **LOCK** button, the horn will sound a short chirp (if enabled) and flash the park lamps to notify that the all door lock signal was received and acted upon. Illuminated entry is cancelled and the interior lamps are faded to off.
- Pushing the **PANIC** button will cause the panic alarm to sound for three minutes, until the panic button is pressed a second time, or until the vehicle reaches a speed of 15 mph.

REMOTE KEYLESS ENTRY TRANSMITTER (Continued)

DIAGNOSIS AND TESTING - REMOTE KEYLESS ENTRY TRANSMITTER

Using special tool 9001, first test to ensure that the transmitter is functioning. Typical testing distance is 2.5 centimeters (1 inch) for Asian transmitters and 30.5 centimeters (12 inches) for all others. To test, position the transmitter as shown (Fig. 4). Press any transmitter button, then test each button individually. The tool will beep if a radio signal strength that lights five or more LED's is detected. Repeat this test three times. If transmitter fails any of the test refer to the Diagnostic Procedures manual.

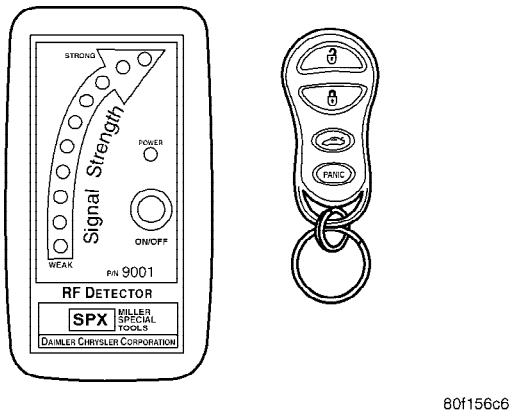

Fig. 4 RKE TRANSMITTER DIAGNOSIS

STANDARD PROCEDURE

STANDARD PROCEDURE - HORN CHIRP TOGGLE

The toggling of the horn chirp (between enabled and disabled) can be performed with the use of the DRB III® scan tool or by the customer.

DRB III® PROGRAMMING

When using the DRB lll® scan tool, select:
(1) “Theft Alarm”
(2) “VTSS”
(3) “Miscellaneous”
and then the desired function.

CUSTOMER PROGRAMMING

Using a transmitter programmed to the RKE Module, the status of the horn chirp may be toggled by the customer.

NOTE: The RKE Module is responsible for keeping track of the horn chirp status; thus this procedure does not need to be repeated for each transmitter programmed to the system.

(1) With the ignition switch in RUN position, press and hold the transmitter Unlock button for a minimum of 4 seconds to a maximum of 10 seconds.

(2) While holding the UNLOCK button for 4-10 seconds, press the LOCK button. A chime will be heard to indicate a successful toggle, at which time both buttons may be released.

STANDARD PROCEDURE - TRANSMITTER PROGRAMING

New Remote Keyless Entry (RKE) transmitters can be programed using the DRBIII® scan tool and the proper Diagnostic Procedures manual, if no functioning transmitter is available.

The following procedure can be used as long as one functioning transmitter is available:

(1) Insert the key into the ignition switch, and turn the ignition switch to the RUN position (without starting the vehicle).

(2) Using the RKE transmitter programmed to the RKE module, press and continuously hold down the UNLOCK button for 4-10 seconds.

(3) Within the 4-10 second time range, continue to hold the UNLOCK button and press the PANIC button. Both buttons may then be released. Upon the PANIC button being depressed, the message for customer programming mode will be transmitted to the RKE module.

(4) A chime will be heard to verify that the customer programming mode has been entered.

(5) Press and release any button on each transmitter that is to be programmed to the RKE module, including any transmitters which were previously programmed to the RKE module (with a maximum of four possible). After each transmitter is successfully programmed, a chime will be heard to verify that successful programming of the transmitter has occurred.

(6) After thirty seconds, or upon the ignition switch being turned OFF, a chime will indicate that the RKE module has exited the programming mode.

STANDARD PROCEDURE - RKE TRANSMITTER BATTERIES

The Remote Keyless Entry (RKE) transmitter case snaps open and shut for battery access. To replace the RKE transmitter batteries:

(1) Using a thin coin, gently pry at the notch in the center seam of the RKE transmitter case halves near the key ring until the two halves unsnap.

(2) Lift the back half of the transmitter case off of the RKE transmitter.

(3) Remove the two batteries from the RKE transmitter.

REMOTE KEYLESS ENTRY TRANSMITTER (Continued)

(4) Replace the two batteries with new Panasonic 2016, or equivalent. Be certain that the batteries are installed with their polarity correctly oriented.

(5) Align the two RKE transmitter case halves with each other, and squeeze them firmly and evenly together until they snap back into place.

SPECIFICATIONS - TRANSMITTER RANGE

Normal operation range is within 7 meters (23 ft.) of the vehicle. Range may be better or worse depending on the environment around the vehicle.

INSTALLATION 11

POWER MIRRORS

DESCRIPTION

The mirrors are controlled by a single switch assembly located on the front left lower instrument panel (LHD) or on the front right lower instrument panel (RHD). The push button switch (LHD) or rocker switch (RHD) uses L (left) and R (right) for mirror selection and a button to push for the desired direction of mirror movement.

The motors which operate the mirrors are part of the mirror assembly and cannot be replaced separately.

These vehicles may be equipped with power foldaway mirrors. This feature allows both the driver and passenger side view mirrors to fold inward (retract) on demand. The vehicle has an additional switch located below the power mirror switch that controls the folding function of the mirror assembly.

The foldaway side view mirror is attached to the vehicle's door in the same manner as mirrors without the foldaway option. The foldaway mirrors unique option is the internal motor which allows the mirrors to fold inward. The fold-away mirror motor is not serviceable separately and if a motor is found to be faulty, the entire side view mirror must be replaced.

OPERATION

Use the mirror select switch, located to the left of the steering column on the instrument panel, to adjust the view obtained in the outside mirrors. Press the L or R button for Left or Right mirror selection. Use the center off position to guard against accidentally moving a mirror position.

Select a mirror and press one of the four arrows for the direction you want the mirror to move.

DIAGNOSIS AND TESTING - POWER MIRRORS

WIRING VOLTAGE TEST (LHD)

The following wiring test determines whether or not voltage is continuous through the body harness to switch.

(1) Remove the power mirror switch.

(2) Disconnect wire connector from back of power mirror switch.

(3) Connect the clip end of a 12 volt test light to Pin 7 in the harness connector at the mirror switch. Touch the test light probe to Pin 3.

If the test light illuminates, the wiring circuit between the battery and switch is OK.

If the lamp does not illuminate, first check fuse 18 in the Junction Block (JB). If fuse 18 is OK, then check for a broken wire.

Refer to the appropriate wiring information.

POWER MIRROR MOTOR TEST (LHD)

If the power mirror switch is receiving proper current and ground and mirrors do not operate, proceed with power mirror motor test. Refer to the appropriate wiring information.

(1) Disconnect wire harness connector to power mirror switch.

(2) Using two jumper wires:

- Connect one to a 12 volt source
- Connect the other to a good body ground
- Refer to the Mirror Motor Test Chart for proper wire connections at the switch connector.

POWER MIRRORS (Continued)

MIRROR MOTOR TEST CHART

12 VOLTS	GROUND	MIRROR REACTION	
SWITCH CONNECTOR		RIGHT	LEFT
PIN 4	PIN 1	-	UP
PIN 8	PIN 1	-	LEFT
PIN 1	PIN 4	-	DOWN
PIN 1	PIN 8	-	RIGHT
PIN 9	PIN 10	UP	-
PIN 2	PIN 10	LEFT	-
PIN 10	PIN 9	DOWN	-
PIN 10	PIN 2	RIGHT	-

(3) If results shown in table are not obtained, check for open or shorted circuit. Replace mirror assembly as necessary.

POWER MIRROR SWITCH - LHD

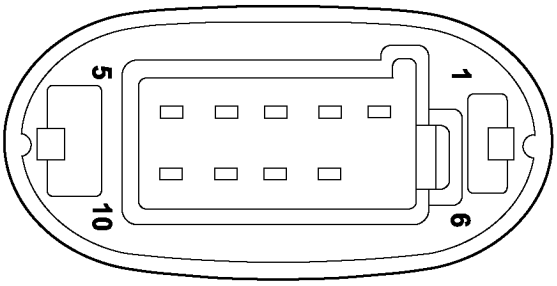
DIAGNOSIS AND TESTING - POWER MIRROR SWITCH - LHD

(1) Disconnect and isolate the battery negative cable.

(2) Remove power mirror switch (Refer to 8 - ELECTRICAL/POWER MIRRORS/POWER MIRROR SWITCH - REMOVAL).

(3) Using an ohmmeter, test for continuity between the terminals of the switch as shown in the Mirror Switch Test table (Fig. 1).

(4) If test results are not obtained as shown in the Mirror Switch Test table, replace the switch.



811677ae

Fig. 1 POWER MIRROR SWITCH

MIRROR SWITCH TEST TABLE

SWITCH POSITION MOVE BUTTON	CONTINUITY BETWEEN TERMINALS
MIRROR IN ″L″ POSITION	
UP	PIN 2 TO 4 PIN 4 TO 7 PIN 8 TO 10
RIGHT	PIN 3 TO 8 PIN 8 TO 9 PIN 4 TO 10
DOWN	PIN 2 TO 8 PIN 7 TO 8 PIN 4 TO 10
LEFT	PIN 3 TO 4 PIN 4 TO 9 PIN 8 TO 10
MIRROR IN ″R″ POSITION	
UP	PIN 2 TO 4 PIN 4 TO 7 PIN 1 TO 8
RIGHT	PIN 1 TO 4 PIN 3 TO 8 PIN 8 TO 9
DOWN	PIN 1 TO 4 PIN 2 TO 8 PIN 7 TO 8
LEFT	PIN 3 TO 4 PIN 1 TO 8 PIN 4 TO 9

REMOVAL

(1) Disconnect and isolate the battery negative cable.

(2) Remove the left lower instrument panel bezel. Pull top rearward, lower to floor and with a quick pulling motion remove off instrument panel.

(3) Remove two screws to the left instrument panel end cover.

(4) Pull the left end cover rearward to unsnap. Maneuver it out from underneath the left A-pillar trim and top cover. Removal of these components is not necessary.

(5) Disconnect the power mirror switch wiring connector and remove end cover from vehicle.

(6) With the left end cover on the bench, gently pry in on the tabs (4) of the mirror switch and push through the front of the cover and remove (Fig. 2).

INSTALLATION

(1) Place the mirror switch in cover opening and firmly snap into place.

(2) Connect the power mirror switch wiring connector.

POWER MIRROR SWITCH - LHD (Continued)

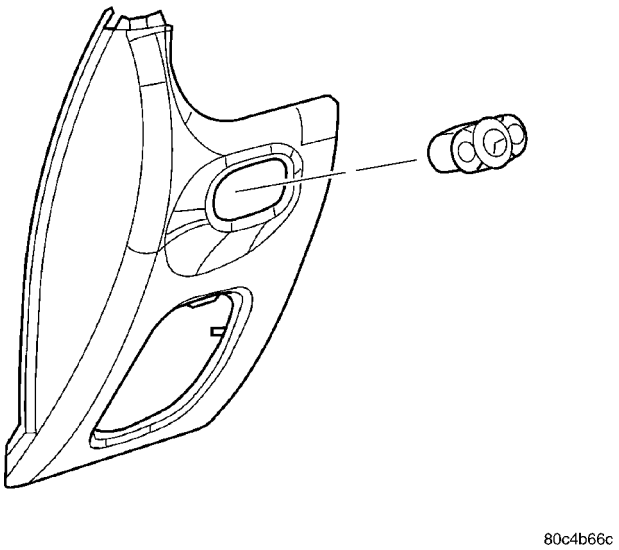


Fig. 2 POWER MIRROR SWITCH

(3) Place the left end cover in position and snap into place. Make sure that it is underneath the A-pillar trim and top cover.

(4) Install two screws to the left instrument panel end cover.

(5) Place left lower instrument panel bezel in position and make sure the orientation of the hinge is correct and snap bezel hinge into place

(6) Roll bezel upward and snap into place.

(7) Connect the battery negative cable.

POWER FOLDAWAY MIRROR SWITCH - RHD

DIAGNOSIS AND TESTING - POWER FOLDAWAY MIRROR SWITCH - RHD

The following test is designed to be used only on vehicles equipped with power fold away side view mirrors.

(1) Remove power mirror switch from mounting position (Refer to 8 - ELECTRICAL/POWER MIRRORS/POWER FOLDAWAY MIRROR SWITCH - REMOVAL).

(2) Using an ohmmeter, test for continuity between the terminals of the switch as shown in the tables below (Fig. 3).

NOTE: When testing using the chart below be certain to read the chart correctly. Example - When testing left mirror "DOWN↓", pins 1, 9, 10 will show continuity to each other but not with 3, 4, 5.

(3) If test results are not obtained as shown in the tables below, replace the switch.

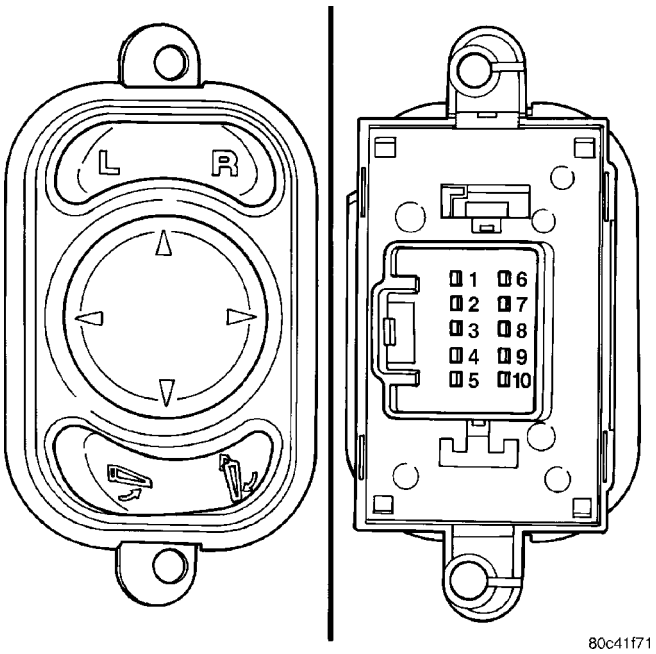

Fig. 3 POWER FOLDAWAY MIRROR SWITCH

EXTENDED MIRROR SWITCH CIRCUIT TEST

NOTE: MIRROR POSITION SWITCH MUST BE IN THE "EXTENDED" POSITION TO USE CHART BELOW.

WOBBLE PLATE POSITION	LEFT MIRROR SELECTED	RIGHT MIRROR SELECTED
	CONTINUITY BETWEEN PINS	CONTINUITY BETWEEN PINS
DOWN	1, 9, 10 3, 4, 5	6, 9, 10 3, 4, 5
UP	1, 4, 5 3, 9, 10	6, 4, 5 3, 9, 10
RIGHT	2, 9, 10 3, 4, 5	7, 9, 10 3, 4, 5
LEFT	2, 4, 5 3, 9, 10	7, 4, 5 3, 9, 10

POWER FOLDAWAY MIRROR SWITCH - RHD (Continued)

RETRACTED MIRROR SWITCH CIRCUIT TEST

NOTE: MIRROR POSITION SWITCH MUST BE IN THE "RETRACTED" POSITION TO USE CHART BELOW.

WOBBLE PLATE POSITION	LEFT MIRROR SELECTED	RIGHT MIRROR SELECTED
	CONTINUITY BETWEEN PINS	CONTINUITY BETWEEN PINS
DOWN	1, 3, 4, 9	3, 4, 6, 9
UP	1, 3, 4, 9	3, 4, 6, 9
RIGHT	2, 3, 4, 9	3, 4, 7, 9
LEFT	2, 3, 4, 9	3, 4, 7, 9

REMOVAL

(1) Disconnect and isolate the battery negative cable.

(2) Remove the lower instrument panel bezel from under steering column.

(3) Remove the instrument panel end cover retaining screws and pull rearward to release retaining clips.

(4) Disconnect power mirror switch electrical connector (Fig. 4).

(5) Remove the mirror switch retaining screws and remove the switch from the end cover.

INSTALLATION

(1) Connect mirror switch electrical connector to switch.

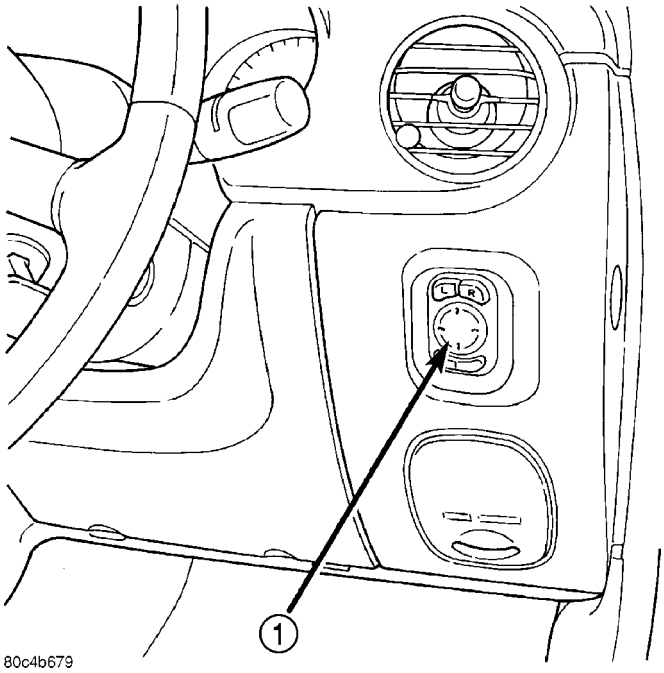

Fig. 4 POWER FOLD AWAY MIRROR SWITCH

1 - POWER FOLDAWAY MIRROR SWITCH

(2) Install switch retaining screws holding switch to end cover.

(3) Install the lower instrument panel bezel.

(4) Connect battery negative cable.

POWER SEAT SYSTEM

DESCRIPTION

A driver's side power front seat is available on this vehicle. The power seat system allows the driver to electrically adjust the seating position for optimum control and comfort using the power seat switch located on the outboard seat cushion side shield of the drivers front seat.

The power seat system includes the following major components:

- Power Driver Seat Switch
- Power Seat Track Assembly
- Circuit Breaker
- Wire Harness

WARNING: SOME VEHICLES ARE EQUIPPED WITH SEATBACK MOUNTED AIRBAGS (Fig. 1). BEFORE ATTEMPTING TO DIAGNOSE OR SERVICE ANY SEAT OR POWER SEAT SYSTEM COMPONENT YOU MUST FIRST DISCONNECT AND ISOLATE THE BATTERY NEGATIVE CABLE. THEN WAIT TWO MINUTES FOR THE SYSTEM CAPACITOR TO DISCHARGE BEFORE FURTHER SYSTEM SERVICE. THIS IS THE ONLY SURE WAY TO DISABLE THE AIRBAG SYSTEM. FAILURE TO DO SO COULD RESULT IN ACCIDENTAL AIRBAG DEPLOYMENT AND POSSIBLE PERSONAL INJURY.

Refer to the appropriate wiring information. The wiring information includes wiring diagrams, proper wire and connector repair procedures, further details on wire harness routing and retention, as well as pin-out and location views for the various wire harness connectors, splices and grounds.

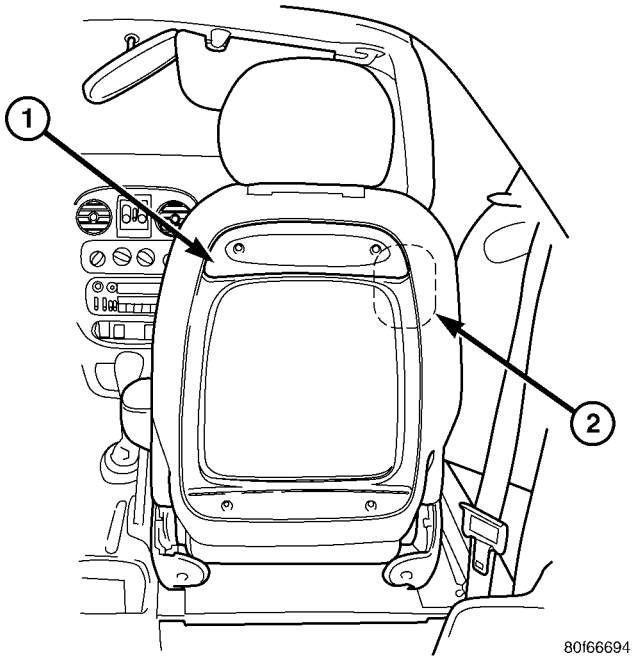

Fig. 1 PT AIRBAG EQUIPPED FRONT SEATS

1 - FRONT SEAT BACK PANEL
2 - INTERNAL AIRBAG LOCATION

OPERATION

The power seat system receives battery current through a fuse in the Power Distribution Center (PDC) and a circuit breaker in the junction block. The power seat remain operational at all times, regardless of the ignition switch position.

POWER SEAT SYSTEM (Continued)

When the power seat switch paddle is actuated, a battery feed and a ground path are applied through the switch contacts to the power seat track adjuster motor. The motor operates to move the seat track adjuster through its drive unit in the selected direction until the switch is released, or until the travel limit of the adjuster is reached. When the switch is moved in the opposite direction, the battery feed and ground path to the motor are reversed through the switch contacts. This causes the motor to run in the opposite direction.

DIAGNOSIS AND TESTING - POWER SEAT SYSTEM

Before any testing of the power seat system is attempted, the battery should be fully-charged. **Refer to the appropriate wiring information.** The wiring information includes wiring diagrams, proper wire and connector repair procedures, further details on wire harness routing and retention, as well as pin-out and location views for the various wire harness connectors, splices and grounds.

(1) If all power seats are inoperative, check the automatic resetting circuit breaker in the Junction Block (JB).

(2) With the dome lamp on, apply the power seat switch in both directions.

(3) If the dome lamp dims, the seat or the power seat track may be jammed. Check under and behind the seat for binding or obstructions.

(4) If the dome lamp does not dim, proceed with testing of the individual power seat system components and circuits.

POWER SEAT SWITCH

DESCRIPTION

A single two-way momentary power seat switch is located on the outboard seat cushion side shield of the drivers front seat. The power seat switch is secured to the back of the seat cushion side shield with two screws, and the switch paddle protrudes through a hole to the outside of the shield. The switch paddle is located in a shallow depression molded into the outer surface of the seat cushion side shield that helps to shroud it from unintentional actuation when entering or exiting the vehicle.

The power seat switch cannot be adjusted or repaired and, if inoperative or damaged, must be replaced.

OPERATION

When the power seat switch paddle is actuated, a battery feed and a ground path are applied through the switch contacts to the power seat track adjuster motor. The motor operates to move the seat track adjuster through its drive unit in the selected direction until the switch is released, or until the travel limit of the adjuster is reached. When the switch is moved in the opposite direction, the battery feed and ground path to the motor are reversed through the switch contacts. This causes the motor to run in the opposite direction.

The power seat switch should not be held applied in either direction after the adjuster has reached its travel limit. The power seat adjuster motor contains a self-resetting circuit breaker to protect it from overload. However, consecutive or frequent resetting of the circuit breaker must not be allowed to continue, or the motor may be damaged.

DIAGNOSIS AND TESTING - POWER SEAT SWITCH

Before any testing of the power seat system is attempted, the battery should be fully-charged. **Refer to the appropriate wiring information.** The wiring information includes wiring diagrams, proper wire and connector repair procedures, further details on wire harness routing and retention, as well as pin-out and location views for the various wire harness connectors, splices and grounds.

(1) Disconnect and isolate the battery negative cable.

(2) Remove the power seat switch from the outboard seat cushion side shield, (Refer to 8 - ELECTRICAL/POWER SEATS/DRIVER SEAT SWITCH - REMOVAL).

(3) Use an ohmmeter to test the continuity of the power seat switch in each switch position. See the Power Seat Switch Continuity chart (Fig. 2). If OK, (Refer to 8 - ELECTRICAL/POWER SEATS/POWER SEAT TRACK - DIAGNOSIS AND TESTING). If not OK, replace the inoperative power seat switch.

POWER SEAT SWITCH	
SWITCH POSITION	CONTINUITY BETWEEN
Off	2-4, 3-5
UP	3-5, 4-6
DOWN	2-4, 3-6

REMOVAL

(1) Disconnect and isolate the battery negative cable.

(2) Remove two screws to left cushion side shield.

(3) Disconnect wiring from switch.

(4) Remove attaching screws and switch from bezel.

POWER SEAT SWITCH (Continued)

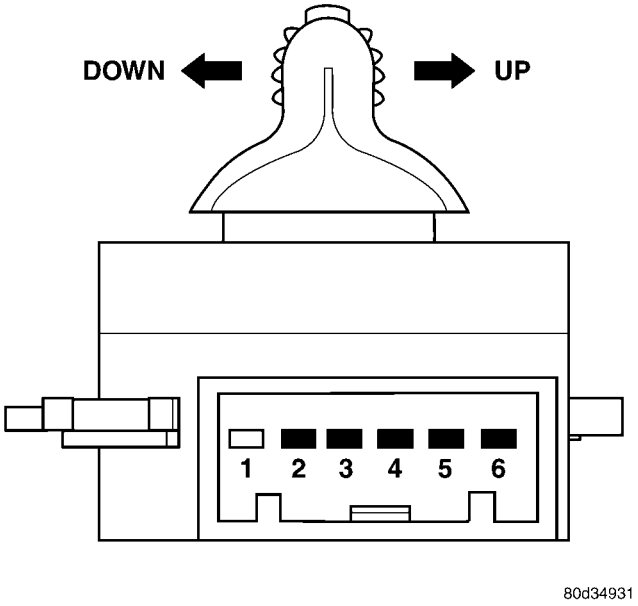

Fig. 2 POWER SEAT SWITCH CONTINUITY CHART / SWITCH PIN-OUT

INSTALLATION

(1) Install switch and two attaching screws to bezel.
(2) Connect wiring to switch.
(3) Install screws to left cushion side shield.
(4) Connect the battery negative cable.
(5) Verify system operation.

POWER SEAT TRACK

DESCRIPTION

The power seat track incorporates a front and rear riser (Fig. 3). These risers are not part of the power seat track and must be removed in order to service the power seat track assembly. One 12v motor is utilized in the power seat track (Fig. 3). The motor is connected to a worm-drive gearbox that moves the seat adjuster up and down. The drivers front seat can be raised or lowered using the power seat switch, located on the outboard side of the seat cushion side shield.

The motor contains a self-resetting circuit breaker to protect it from overload. Consecutive or frequent resetting of the circuit breaker may cause damage to the motor or circuit breaker.

The power seat track cannot be repaired, and is serviced only as a complete assembly. If any component in this unit is inoperative or damaged, the entire power seat track assembly must be replaced.

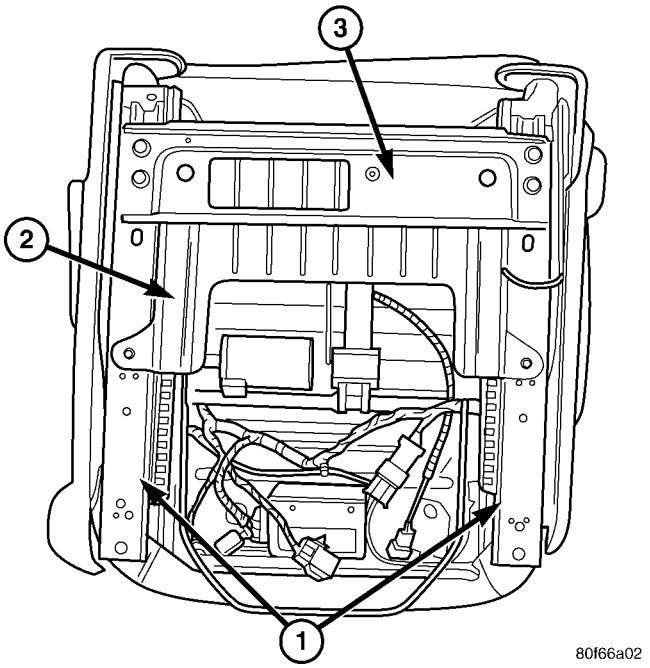

Fig. 3 PT POWER SEAT TRACK

1 - POWER SEAT TRACK
2 - LOWER SEAT TRACK COVER
3 - REAR SEAT CUSHION RISER

OPERATION

One single armature permanent magnet reversible motor is coupled to a worm gear box assembly. It is located in between the seat tracks and upper supports. The one single gear motor assembly attaches to the seat tracks and provide the various seat movements.

The electrical circuit is protected by a 20 amp circuit breaker located in the junction block.

When a power seat switch is actuated, a battery feed and a ground path are applied through the switch contacts to the appropriate motor. The motor and drive operate to move the seat in the selected direction until the power seat switch is released, or until the travel limit of the power seat track adjuster is reached. When the power seat switch is moved in the opposite direction, the battery feed and ground path to the motor are reversed through the switch contacts. This causes the motor and drive to run in the opposite direction.

DIAGNOSIS AND TESTING - POWER SEAT TRACK

Refer to the appropriate wiring information. The wiring information includes wiring diagrams, proper wire and connector repair procedures, further details on wire harness routing and retention, as well as pin-out and location views for the various wire harness connectors, splices and grounds.

POWER SEAT TRACK (Continued)

Operate the power seat switch to move the seat motor in each direction. The seat should move in each of the selected directions. If the power seat track fails to operate in only one direction, move the seat a short distance in the opposite direction and test again to be certain that the adjuster is not at its travel limit. If the power seat track still fails to operate in only one direction, begin by testing the power seat switch, (Refer to 8 - ELECTRICAL/POWER SEATS/DRIVER SEAT SWITCH - DIAGNOSIS AND TESTING). If the power seat track fails to operate in more than one direction, proceed as follows:

(1) Test the circuit breaker in the Junction Block (JB). If OK, go to Step 2. If not OK, replace the inoperative circuit breaker.

(2) Remove the power seat switch from the seat, (Refer to 8 - ELECTRICAL/POWER SEATS/DRIVER SEAT SWITCH - REMOVAL). Check for battery voltage at the fused B(+) circuit cavity of the power seat wire harness connector for the power seat switch. If OK, go to Step 3. If not OK, repair the open fused B(+) circuit between the power seat switch and the JB as required.

(3) Check for continuity between the ground circuit cavity of the power seat wire harness connector for the power seat switch and a good ground. There should be continuity. If OK, go to Step 4. If not OK, repair the open circuit to ground as required.

(4) Test the power seat switch, (Refer to 8 - ELECTRICAL/POWER SEATS/DRIVER SEAT SWITCH - DIAGNOSIS AND TESTING). If the switch tests OK, test the circuits of the power seat wire harness between the power seat switch and the inoperative motor for shorts or opens. If the circuits check OK, replace the inoperative power seat track. If the circuits are not OK, repair the power seat wire harness as required.

REMOVAL

(1) Disconnect and isolate the battery negative cable.

(2) Remove the power seat from the vehicle and set face down on a clean surface. (Refer to 23 - BODY/SEATS/SEAT - REMOVAL)

(3) Remove the bolts retaining the front riser and set the front seat riser aside (Fig. 4).

(4) Remove the bolts retaining the rear riser (Fig. 5) and set the seat riser aside.

(5) Remove the lower seat track cover screws and set it aside.

(6) Remove the seat cushion side shields and set aside.

(7) Disengage and disconnect the power seat wire harness from the power seat track.

(8) Remove the power seat track retaining fasteners and remove the power seat track from the seat.

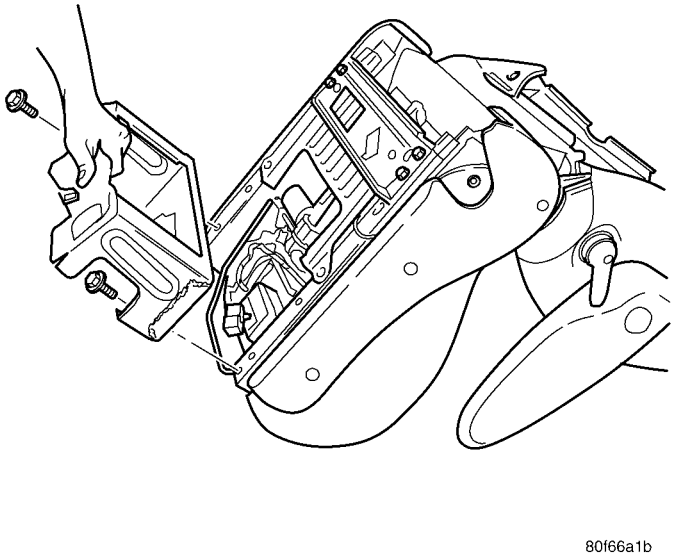

Fig. 4 SEAT FRONT RISER REMOVAL/ INSTALLATION

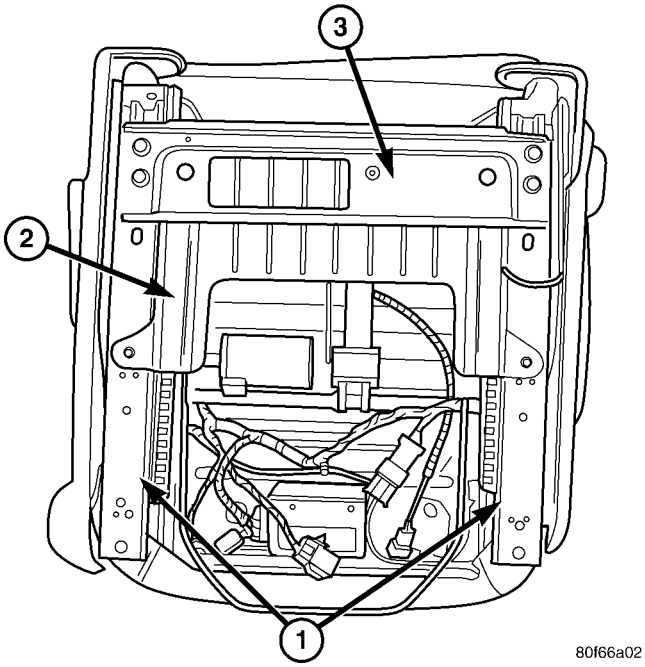

Fig. 5 POWER SEAT TRACK

1 - POWER SEAT TRACK
2 - LOWER SEAT TRACK COVER
3 - REAR SEAT CUSHION RISER

INSTALLATION

(1) Reinstall the power seat track onto the seat cushion frame. Torque bolts to 21 ft. lbs. (28 N·m).

(2) Secure and connect the power seat wire harness on the power seat track.

POWER SEAT TRACK (Continued)

(3) Install the seat cushion side shields.
(4) Install the lower seat track cover.
(5) Install the bolts retaining the rear riser. Torque bolts to 21 ft. lbs. (28 N·m).
(6) Install the bolts retaining the front riser. Torque bolts to 21 ft. lbs. (28 N·m).
(7) Reinstall the power seat assembly into the vehicle, (Refer to 23 - BODY/SEATS/SEAT - INSTALLATION). Torque bolts to 45 ft. lbs. (61 N·m).
(8) Reconnect the battery negative cable.

LUMBAR

DESCRIPTION

Some vehicles are equipped with a mechanical lumbar support mechanism (Fig. 6). The only visible evidence of this option is the separate lumbar control lever that is located on the inboard seat cushion side shield. The lumbar adjuster and cable are concealed beneath the seat back trim cover and padding, where they are secured to the seat back frame.

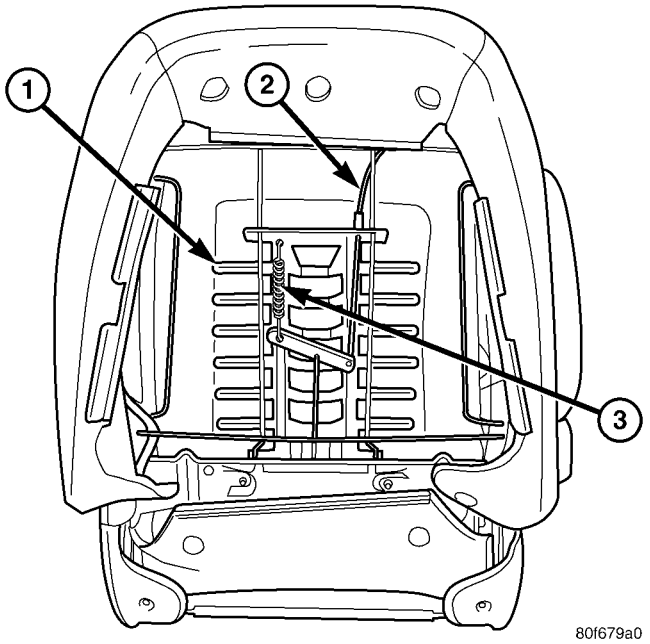

Fig. 6 PT LUMBAR ASSEMBLY

1 - LUMBAR ASSEMBLY
2 - LUMBAR CONTROL CABLE
3 - SPRING

OPERATION

The lumbar adjuster lever, located on the inboard side of each front seat attaches to a cable located inside the seat back. This cable/lever operates the lumbar adjuster mechanism. When the lumbar adjuster lever is moved up/down the attached cable is extended or retracted. The action of this cable compresses or relaxes a grid of flexible slats, located in the seat back. The more this grid is compressed, the more the slats bow outward against the center of the seat back padding, providing additional lumbar support.

REMOVAL

(1) Partially remove the seat back trim cover from the seat back frame. Refer to the Body section for the procedure.
(2) Disconnect the lumbar mechanism spring and disconnect the cable from the lumbar assembly.
(3) Unsnap the lumbar assembly from the seat back frame and remove from the seat.

INSTALLATION

(1) Snap the lumbar assembly on the seat back frame. Be careful not to break the retaining pins, if broken replace with new pieces.
(2) Connect the lumbar cable and connect the mechanism spring on the lumbar assembly.
(3) Install the seat back trim cover on the seat back frame. Refer to the Body section for the procedure.

POWER TOP - CONVERTIBLE - PT27

DESCRIPTION

The power top system allows the convertible top to be raised and lowered electrically by actuating a switch on the instrument panel. The power top system receives battery feed through a fuse in the Power Distribution Center (PDC), only when the ignition switch is in the ON position.

In each door there is a window regulator module directly connected to each of the front door window regulator motors. The window regulator module receives battery feed through a circuit breaker in the fuse block, only when the ignition switch is in the ON position. The modules control window motor operation and smart glass functions. The driver window module controls the convertible top operations by supplying a ground signal to the motor/hydraulic pump relay.

The main components of the power top system (Fig. 1) are:

- The power top framework and bows
- The motor/hydraulic pump assembly
- The power top well
- The power top pivot bracket
- The latch system
- The window regulator modules

The power top motor is part of the motor/hydraulic pump assembly and cannot be serviced separately. If the motor is inoperative the complete assembly must be replaced, (Refer to 23 - BODY/CONVERTIBLE TOP/MOTOR/HYDRAULIC PUMP ASSEMBLY-REMOVAL).

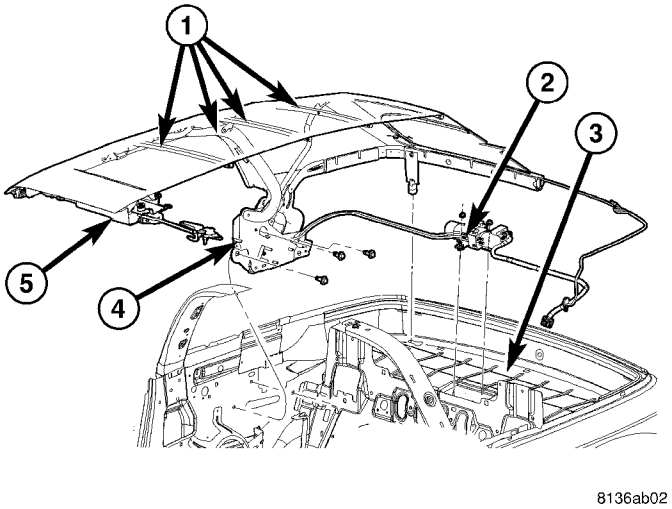

Fig. 1 POWER TOP COMPONENTS

1 - POWER TOP FRAMEWORK
2 - MOTOR/HYDRAULIC PUMP ASSEMBLY
3 - POWER TOP WELL
4 - POWER TOP PIVOT BRACKET
5 - LATCH SYSTEM

OPERATION

The power top switch is hard wired to both window regulator modules by the Power Top Switch Mux circuit. When a top operation input is received by the driver window regulator module, it will ground the respective relay control circuit which in turn will operate the power top motor. If the power top switch is pressed and held to the down position second detent, it will command both modules to drop all windows to the fully down position. The windows cannot be raised when the power top switch is in the top down position.

POWER TOP - CONVERTIBLE - PT27 (Continued)

When the switch is held in the top up position and all four windows are fully up, the modules will lower the respective front window 40mm, lower the respective rear window for 0.52 seconds (approx. 55mm) and the driver window regulator module will ground the top up relay control circuit. Once the top is back up the windows will not raise automatically. When the top switch is pressed in either position, the driver window regulator module will ground the respective relay control circuit for a maximum of 30 seconds. The window regulator module monitors vehicle speed and if the speed is over 15 mph. the top will not operate. (Refer to 8 - ELECTRICAL/POWER WINDOWS/WINDOW REGULATOR MODULE - DESCRIPTION) for additional information on the window regulator module.

DIAGNOSIS AND TESTING

POWER TOP - CONVERTIBLE

Any diagnosis of the power top system should begin with the use of a scan tool and the proper Diagnostic Procedures Information. The scan tool can provide confirmation that the Programmable Communications Interface (PCI) data bus is functional, that all of the electronic modules are sending and receiving the proper messages on the PCI data bus, and that the power top motor is being sent the proper hard wired output by the driver window regulator module.

Refer to the appropriate diagnostic information.

MOTOR/HYDRAULIC PUMP ASSEMBLY

DIAGNOSIS AND TESTING

MOTOR/HYDRAULIC PUMP ASSEMBLY

Any diagnosis of the power top system should begin with the use of a scan tool and the proper Diagnostic Procedures Information. The scan tool can provide confirmation that the Programmable Communications Interface (PCI) data bus is functional, that all of the electronic modules are sending and receiving the proper messages on the PCI data bus, and that the power top motor is being sent the proper hard wired output by the driver window regulator module.

If the power top is completely inoperative and the motor/hydraulic pump assembly is suspect, perform the following:

(1) Disconnect and isolate the battery negative cable.

(2) Remove the rear seat back, (Refer to 23 - BODY/SEATS/SEAT BACK - REMOVAL).

(3) Remove the well liner/carpet from the power top well.

(4) Remove the foam pump cover from over the motor/hydraulic pump.

(5) Disconnect the motor/hydraulic pump wire harness connector (Fig. 2).

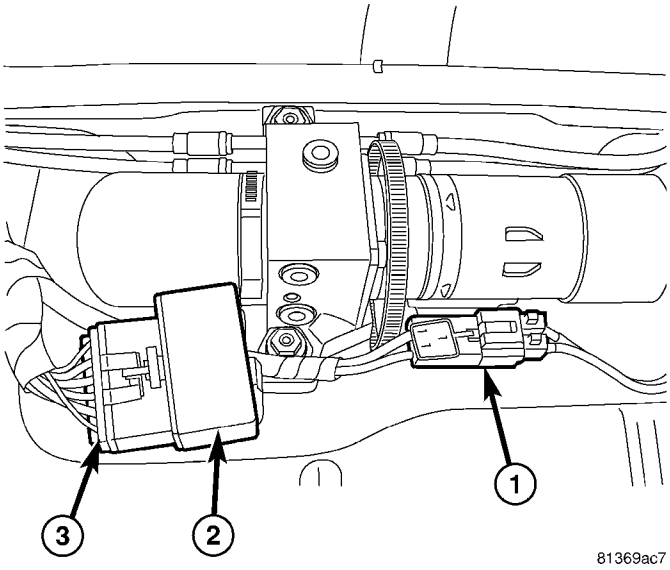

Fig. 2 MOTOR/HYDRAULIC PUMP ASSEMBLY

1 - MOTOR/HYDRAULIC PUMP CONNECTOR
2 - MOTOR/HYDRAULIC PUMP RELAY
3 - MOTOR/HYDRAULIC PUMP RELAY CONNECTOR

(6) Reconnect the battery negative cable.

(7) Insert a 12V test light between the two connector terminals of the motor/hydraulic pump wire harness connector.

(8) With the ignition in the “RUN” position, operate the power top in both directions while observing the test light. The light should illuminate in both directions. If OK, replace the inoperative motor/hydraulic pump assembly, (Refer to 8 - ELECTRICAL/POWER TOP/MOTOR - REMOVAL). If not OK, use a scan tool and the proper Diagnostic Procedures Information to complete diagnosis of the power top system.

RELAY - POWER TOP

REMOVAL

(1) Start with the folding top in the raised and latched position.

(2) Disconnect and isolate the battery negative cable.

(3) Remove the rear seat back, (Refer to 23 - BODY/SEATS/SEAT BACK - REMOVAL).

(4) Remove the well liner/carpet from the power top well.

(5) Remove the foam pump cover from over the motor/hydraulic pump.

(6) Disconnect the motor/hydraulic pump relay wire harness connector (Fig. 3).

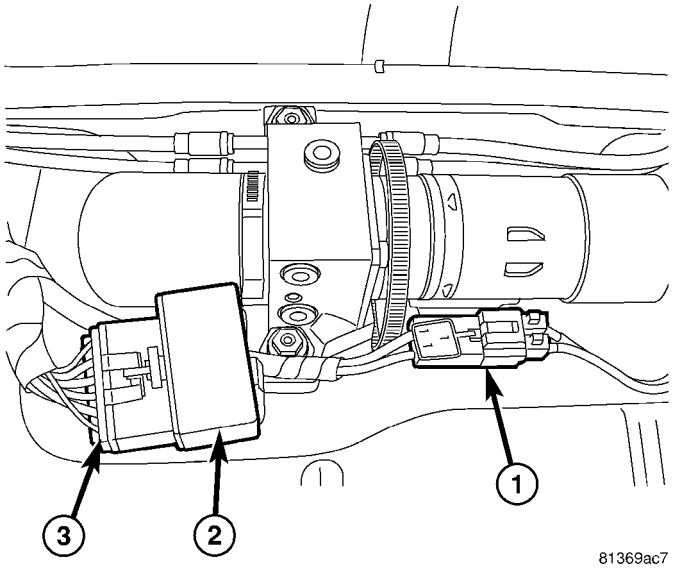

Fig. 3 MOTOR/HYDRAULIC PUMP ASSEMBLY

1 - MOTOR/HYDRAULIC PUMP CONNECTOR
2 - MOTOR/HYDRAULIC PUMP RELAY
3 - MOTOR/HYDRAULIC PUMP RELAY CONNECTOR

(7) Depress the relay retaining tab and remove the relay from the bracket.

INSTALLATION

(1) Position the motor/hydraulic pump relay onto the relay bracket and push into place so that the retaining tab is fully seated.

(2) Connect the motor/hydraulic pump relay wire harness connector (Fig. 4).

(3) Install the foam pump cover.

(4) Install the well liner/carpet into the power top well.

(5) Install the rear seat back, (Refer to 23 - BODY/SEATS/SEAT BACK - INSTALLATION).

(6) Connect the battery negative cable.

(7) Verify normal power top system operation.

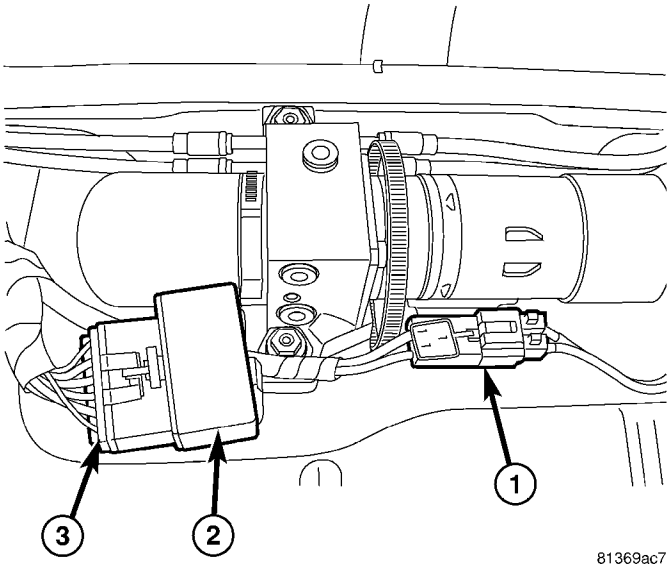

Fig. 4 MOTOR/HYDRAULIC PUMP ASSEMBLY

1 - MOTOR/HYDRAULIC PUMP CONNECTOR
2 - MOTOR/HYDRAULIC PUMP RELAY
3 - MOTOR/HYDRAULIC PUMP RELAY CONNECTOR

SWITCH - POWER TOP

DESCRIPTION

The power top switch is located in the instrument panel center stack mounted to the accessory switch bezel (Fig. 5).

The power top switch is a resistor, multiplexed unit that is hard wired to both window regulator modules, (Refer to 8 - ELECTRICAL/POWER WINDOWS/ WINDOW REGULATOR MODULE - DESCRIPTION) for additional information. The power top switch performs the following functions:

- Power top up (switch pushed upward)
- Power top down (switch pushed downward to the first position)
- Power top express down/all windows down (switch pushed downward to the second position and held in place)

The power top switch cannot be adjusted or repaired. If the switch is damaged or inoperative it must be replaced, (Refer to 8 - ELECTRICAL/ POWER TOP/SWITCH - REMOVAL).

OPERATION

The power top switch is hard wired to both window regulator modules. The switch sends a signal to the modules of varying resistances depending on what position the switch is in. The driver window regulator module uses this resistance signal to perform one of the following functions:

- Power top up (switch pushed upward)

SWITCH - POWER TOP (Continued)

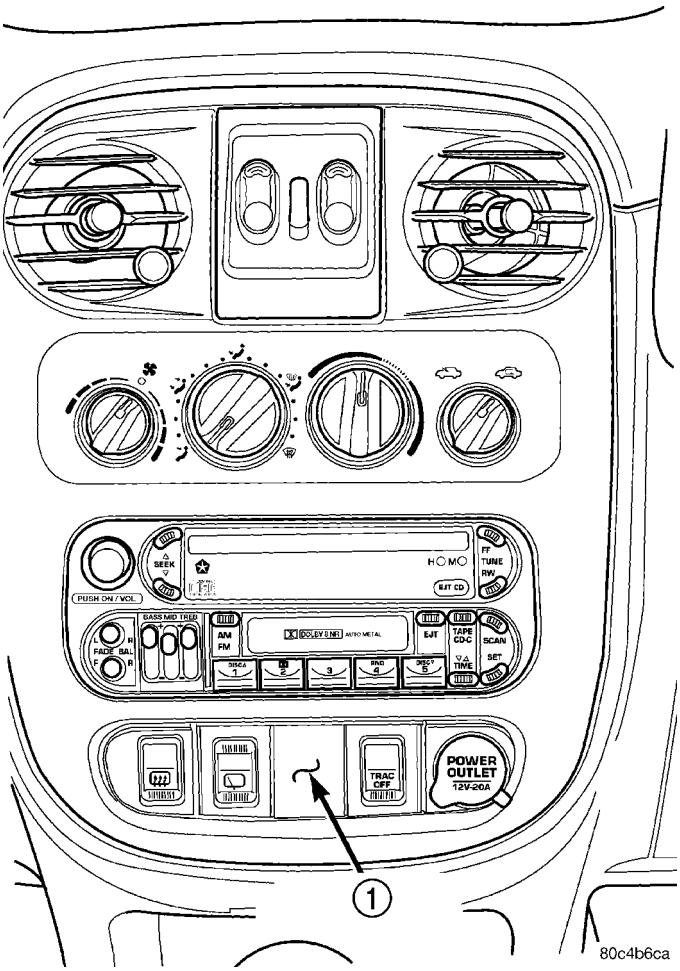

Fig. 5 ACCESSORY SWITCH BEZEL LOCATION

1 - ACCESSORY SWITCH BEZEL

- Power top down (switch pushed downward to the first position)
- Power top express down/all windows down (switch pushed downward to the second position and held in place)

DIAGNOSIS AND TESTING

SWITCH - POWER TOP

Any diagnosis of the power top system should begin with the use of a scan tool and the proper Diagnostic Procedures Information. The scan tool can provide confirmation that the Programmable Communications Interface (PCI) data bus is functional, that all of the electronic modules are sending and receiving the proper messages on the PCI data bus, and that the power top motor is being sent the proper hard wired output by the driver window regulator module.

If the problem being diagnosed is an inoperative power top switch illumination lamp, but the power top switch operates as designed, replace the faulty power top switch. For complete circuit diagrams, refer to the appropriate wiring information. The wiring information includes wiring diagrams, proper wire and connector repair procedures, details of wire harness routing and retention, connector pin-out information and location views for the various wire harness connectors, splices and grounds.

(1) Disconnect and isolate the battery negative cable.

(2) Remove the power top switch, (Refer to 8 - ELECTRICAL/POWER TOP/SWITCH - REMOVAL).

(3) Disconnect the power top switch wire harness connector.

(4) Using an ohmmeter, test the resistances of the power top switch in each switch position. Refer to, (Fig. 6) and the POWER TOP SWITCH TEST CHART. If OK, use a scan tool and the proper Diagnostic Procedures Information to complete diagnosis of the power top system. If not OK, replace the inoperative power top switch, (Refer to 8 - ELECTRICAL/ POWER TOP/SWITCH - REMOVAL).

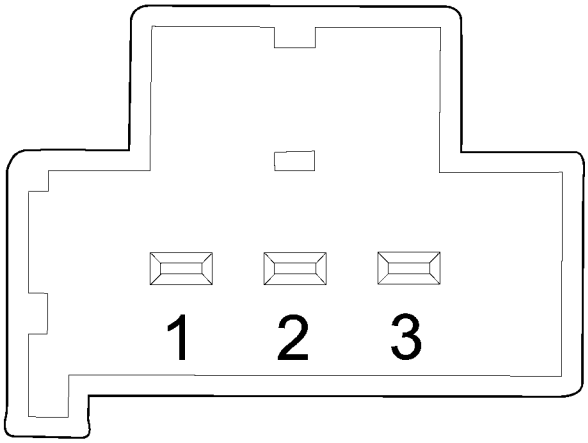

Fig. 6 POWER TOP SWITCH PIN OUT

SWITCH - POWER TOP (Continued)

POWER TOP SWITCH TEST CHART

SWITCH POSITION	RESISTANCE BETWEEN PINS 2 and 3
OFF	4.75 K ohms
TOP UP	596 ohms
TOP DOWN	338 ohms
EXPRESS DOWN	175 ohms
ALL RESISTANCE VALUES ARE ± FIVE PERCENT	

REMOVAL

(1) Disconnect and isolate the battery negative cable.

(2) Remove the instrument panel center bezel, (Refer to 23 - BODY/INSTRUMENT PANEL/INSTRUMENT PANEL CENTER BEZEL - REMOVAL).

(3) Remove two screws retaining the accessory switch bezel (Fig. 7).

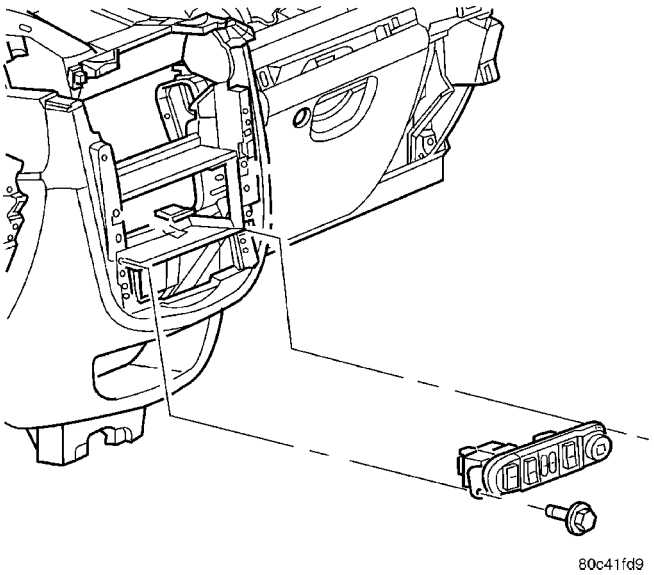

Fig. 7 ACCESSORY SWITCH BEZEL

(4) Disconnect the harness connectors to the following (Fig. 8):

- Power Top Switch
- Rear Window Defogger Switch (if equipped)
- Traction Control Switch (if equipped)
- Cigar Lighter/Power Outlet

(5) To remove the power top switch from the bezel, use both thumbs and slightly pull out on the two retaining tabs holding the switch (Fig. 9).

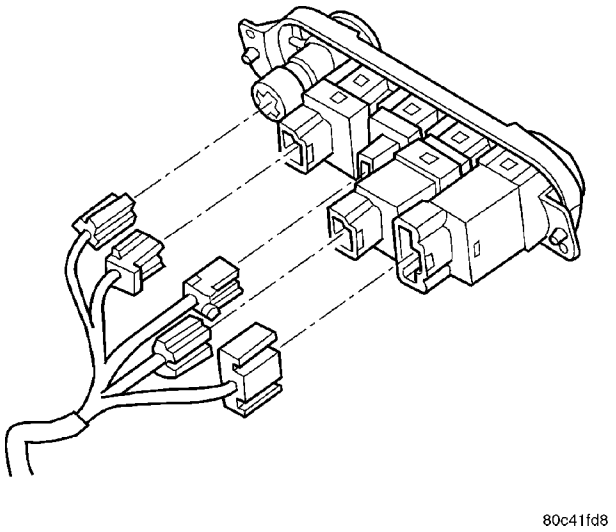

Fig. 8 ACCESSORY SWITCH BEZEL CONNECTORS

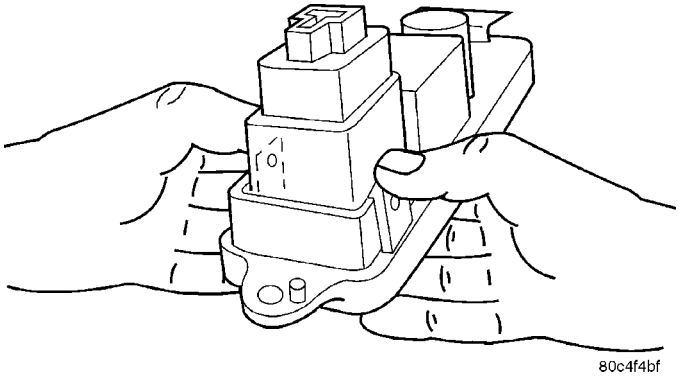

Fig. 9 ACCESSORY SWITCH BEZEL SWITCH

SWITCH - POWER TOP (Continued)

INSTALLATION

(1) From the rear of the switch bezel, gently push the power top switch in until it is secured by the two retaining tabs (Fig. 10).

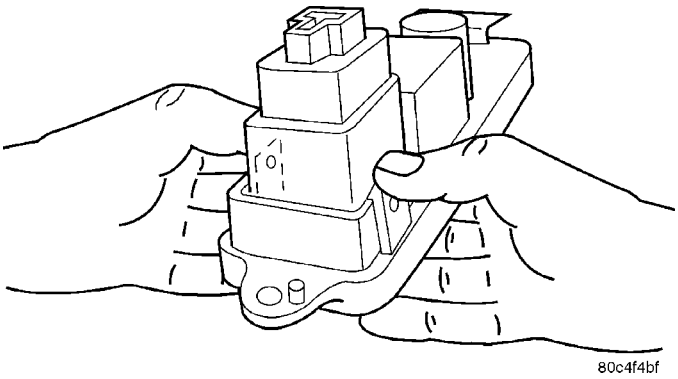

Fig. 10 ACCESSORY SWITCH BEZEL SWITCH

(2) Reconnect the accessory switch bezel connectors (Fig. 11).

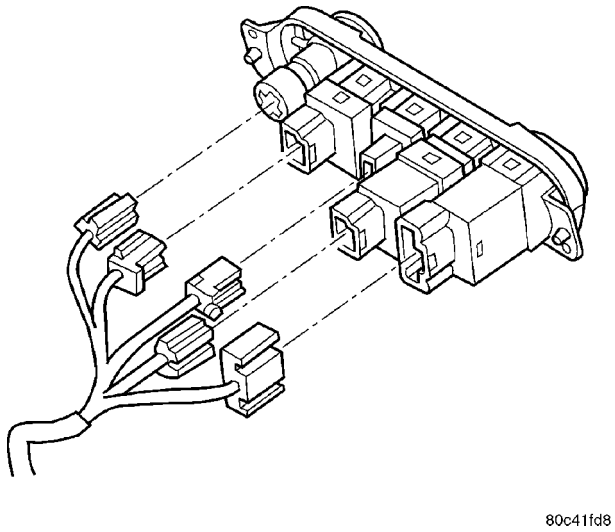

Fig. 11 ACCESSORY SWITCH BEZEL CONNECTORS

(3) Reinstall switch bezel into instrument panel opening and install two retaining screws (Fig. 12).

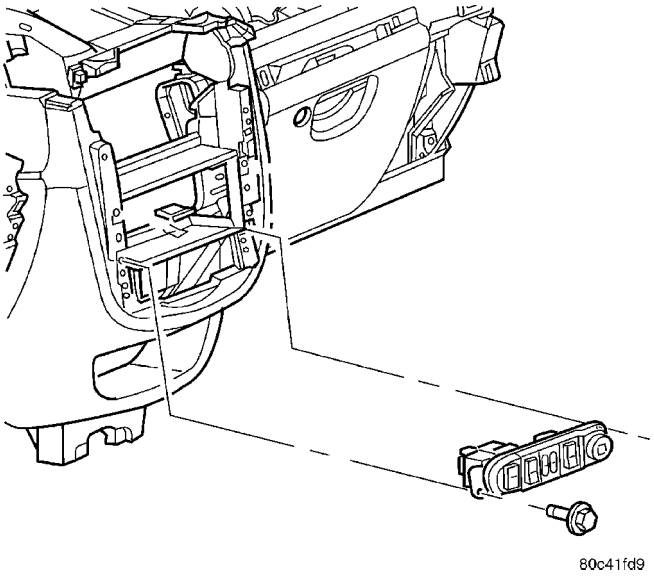

Fig. 12 ACCESSORY SWITCH BEZEL

(4) Reinstall instrument panel center bezel, (Refer to 23 - BODY/INSTRUMENT PANEL/INSTRUMENT PANEL CENTER BEZEL - INSTALLATION).

(5) Connect the battery negative cable.

(6) Verify power top system operation.

POWER TOP - SUNROOF

DESCRIPTION

WARNING: Keep fingers and other body parts out of sunroof opening at all times.

The power sunroof system allows the sunroof to be opened, closed or placed in the vent position electrically by actuating a switch located in the overhead console in between the two reading lamps. The sunroof system receives battery feed through a 30 amp circuit breaker in the junction block. The sunroof system power is supplied when the ignition switch is in the RUN and ACCESSORY positions. The sunroof will continue to operate normally with the key in the OFF position or with the key removed while the Accessory Delay System is active.

The sunroof glass panel tilts upward at the rear for ventilation and slides rearward under the roof when open. The panel seals flush with the roof in the closed position to eliminate wind noise. The sunroof includes a manual-sliding sunshade to cover the deep-tinted glass panel.

The sunroof is electrically operated from two switches located in the overhead console in between the two reading lamps. The “VENT” switch is a push button type switch and opens the sunroof to the vent position only. The other switch “OPEN/CLOSED” is a rocker type switch for opening and closing the sunroof. Pressing and releasing the open button once, the sunroof will express open and the wind deflector will raise. If the button is pressed a second time the sunroof will stop in that position. Pressing and holding the close button will close the sunroof. If the close button is released the sunroof will stop in that position.

OPERATION

This vehicle has a vent, tilt and slide power sunroof system with express (one-touch) open feature. The sunroof system receives battery feed through a 30 amp circuit breaker in the junction block. The sunroof system power is supplied when the ignition switch is in the RUN and ACCESSORY positions. The sunroof will operate normally with the key in any position while the Accessory Delay system is active.

The sunroof is electrically operated from two switches located in the overhead console in between the two reading lamps. The “VENT” switch is a push button type switch and opens the sunroof to the vent position only. The other switch “OPEN/CLOSED” is a rocker type switch for opening and closing the sunroof. Pressing and releasing the open button once, the sunroof will express open and the wind deflector will raise. If the button is pressed a second time the sunroof will stop in that position. Pressing and holding the close button will close the sunroof. If the close button is released the sunroof will stop in that position.

DIAGNOSIS AND TESTING

SUNROOF

Refer to SUNROOF DIAGNOSIS CHART for possible causes. Before beginning sunroof diagnostics verify that all other power accessories are in proper operating condition. If not, a common electrical problem may exist.

POWER TOP - SUNROOF (Continued)

Check the condition of the circuit protection and inspect all wiring connector pins for proper engagement and continuity. For complete circuit diagrams, refer to the appropriate wiring information. The wiring information includes wiring diagrams, proper wire and connector repair procedures, details of wire harness routing and retention, connector pin-out information and location views for the various wire harness connectors, splices and grounds.

SUNROOF DIAGNOSIS CHART

SYMPTOM	POSSIBLE CAUSE	CORRECTION
Sunroof completely inoperative.	Inoperative control switch.	Perform sunroof switch diagnostics, (Refer to 8 - ELECTRICAL/POWER TOP/SWITCH - DIAGNOSIS AND TESTING).
	Inoperative circuit ground between sunroof motor/module, control switch, and body harness.	Inspect ground connections and wiring. Repair as necessary.
	Inoperative power circuit between sunroof motor/module, control switch, and body harness.	Check the condition of the circuit protection and inspect all wiring. Repair as necessary.
	Inoperative sunroof motor/module.	Replace the sunroof motor/module, (Refer to 8 - ELECTRICAL/POWER TOP/MOTOR - REMOVAL).
Audible whine when switch is depressed, sunroof does not operate.	Inoperative sunroof motor/module.	Replace the sunroof motor/module, (Refer to 8 - ELECTRICAL/POWER TOP/MOTOR - REMOVAL).
	Binding cable.	Repair or replace binding cable as necessary.
Audible clicking or ratcheting when switch is pressed, sunroof does not operate.	Broken or worn drive cable.	Repair or replace binding cable as necessary.
	Worn drive motor gear.	Replace the sunroof motor/module, (Refer to 8 - ELECTRICAL/POWER TOP/MOTOR - REMOVAL).
	Mechanisms not synchronized.	Synchronize mechanisms, (Refer to 8 - ELECTRICAL/POWER TOP/MOTOR - STANDARD PROCEDURE - SUNROOF MOTOR/MODULE CALIBRATION).
Sunroof vents and opens, but does not close.	Broken or disengaged trough guide.	Repair trough guide as necessary.
	Binding cable.	Repair or replace binding cable as necessary.
	Inoperative sunroof ″CLOSE″ circuit.	Check the condition of the circuit, connections and wiring. Repair as necessary.
	Inoperative control switch.	Perform sunroof switch diagnostics, (Refer to 8 - ELECTRICAL/POWER TOP/SWITCH - DIAGNOSIS AND TESTING).
	Inoperative sunroof motor/module.	Replace the sunroof motor/module, (Refer to 8 - ELECTRICAL/POWER TOP/MOTOR - REMOVAL).

POWER TOP - SUNROOF (Continued)

SYMPTOM	POSSIBLE CAUSE	CORRECTION
Sunroof vents, but does not open.	Binding cable or mechanism.	Repair or replace binding cable as necessary.
	Inoperative sunroof ″OPEN″ circuit.	Check the condition of the circuit, connections and wiring. Repair as necessary.
	Inoperative control switch.	Perform sunroof switch diagnostics, (Refer to 8 - ELECTRICAL/POWER TOP/SWITCH - DIAGNOSIS AND TESTING).
	Inoperative sunroof motor/module.	Replace the sunroof motor/module, (Refer to 8 - ELECTRICAL/POWER TOP/MOTOR - REMOVAL).
Sunroof does not vent	Binding cable or mechanism.	Repair or replace binding cable as necessary.
	Inoperative sunroof ″VENT″ circuit.	Check the condition of the circuit, connections and wiring. Repair as necessary.
	Inoperative control switch.	Perform sunroof switch diagnostics, (Refer to 8 - ELECTRICAL/POWER TOP/SWITCH - DIAGNOSIS AND TESTING).
	Inoperative sunroof motor/module.	Replace the sunroof motor/module, (Refer to 8 - ELECTRICAL/POWER TOP/MOTOR - REMOVAL).
Glass movement not consistant or glass does not operate smoothly	Glass and Track timing. Glass and Track alignment. Cables and Guide alignment.	Perform the necessary adjustments, (Refer to 23 - BODY/SUNROOF/ GLASS PANEL - ADJUSTMENTS).

MOTOR/MODULE - SUNROOF

DIAGNOSIS AND TESTING -

For complete circuit diagrams, refer to the appropriate wiring information. The wiring information includes wiring diagrams, proper wire and connector repair procedures, details of wire harness routing and retention, connector pin-out information and location views for the various wire harness connectors, splices and grounds.

If the power top is completely inoperative perform the following diagnostic steps.

(1) Check the Accessory delay 30 amp Circuit breaker in the Junction Block. If OK, go to Step 2. If not OK, repair the shorted circuit or component as required and replace the inoperative circuit breaker.

(2) Partially remove the headliner to access the sunroof motor/module.

(3) Disconnect the motor/module electrical connector. With the ignition switch in the “RUN” position check for Battery voltage at the Accessory Relay Output terminal of the harness connector. If OK , go to Step 4. If not OK repair the Accessory Relay Output circuit as necessary.

(4) Using an ohmmeter test for continuity between the harness connector ground circuit and a known good ground. Continuity should be present. If OK go to Step 5. If not OK, repair the open ground circuit as necessary.

(5) Turn the ignition switch to the “OFF” position. Reconnect the motor/module electrical connector. With the ignition switch in the “RUN” position check for 5 volts on the “VENT”, “CLOSE” and “OPEN” control circuits at the back side of the motor/module connector. If OK, go to Step 6. If not OK replace the motor/module assembly, (Refer to 8 - ELECTRICAL/ POWER TOP/MOTOR - REMOVAL).

(6) Turn the ignition switch to the “OFF” position. Disconnect the motor/module and sunroof switch electrical connectors. Using an ohmmeter check for continuity on the “VENT”, “CLOSE” and “OPEN” circuits between the motor/module and sunroof switch. Continuity should be present. If OK, (Refer to 8 - ELECTRICAL/POWER TOP/SWITCH - DIAGNOSIS AND TESTING) for diagnosis of the sunroof switch. If not OK, repair the control circuits as necessary.

MOTOR/MODULE - SUNROOF (Continued)

STANDARD PROCEDURE

STANDARD PROCEDURE - POWER SUNROOF TIMING

NOTE: Perform the timing procedures if any of the following conditions exist:

- Glass skewed in the channel
- One side of the glass dropping before the other while moving from “VENT” to “CLOSE”
- Glass reversing direction when closing the sunroof
- Glass will not close or may stop at the wrong location
- The glass may over travel the “OPEN” position and stall the motor
- The glass may over travel the “CLOSE” position and stall the motor

NOTE: The timing of motor/module and the sunroof assembly play a critical roles in the proper function of the sunroof. If the motor/module is removed and the sunroof glass or cables are moved the sunroof module will have to be timed. REFER to the following procedure for the necessary steps.

(1) Perform the motor/module re-initialization procedure, (Refer to 8 - ELECTRICAL/POWER TOP/MOTOR - STANDARD PROCEDURE).

(2) Remove the motor/module, (Refer to 8 - ELECTRICAL/POWER TOP/MOTOR - REMOVAL).

(3) Remove sunroof glass panel (Refer to 23 - BODY/SUNROOF/GLASS PANEL - REMOVAL).

(4) Now place both right and left arms in the closed position. Using a screwdriver, push the plastic cable all the way forward in the track until the glass mounting arm drops into the closed position.

(5) Repeat this on the other side.

(6) To verify correct timing, there is an 1/8 inch hole in the cable ramp that must be aligned with the front glass mounting screw hole.

(7) Using an awl, verify alignment of both right and left timing holes. The tracks will now be timed to the fully closed position.

(8) Install the motor/module (Refer to 8 - ELECTRICAL/POWER TOP/MOTOR - INSTALLATION).

(9) Install the sunroof glass panel, (Refer to 23 - BODY/SUNROOF/GLASS PANEL - INSTALLATION).

(10) Perform the motor/module re-initialization procedure, (Refer to 8 - ELECTRICAL/POWER TOP/MOTOR - STANDARD PROCEDURE).

STANDARD PROCEDURE - RE-INITIALIZATION

NOTE: If for some reason the sunroof is not operating normally it may be necessary to re-initialize the sunroof assembly. This procedure should be attempted prior to any diagnosis of the sunroof system.

NOTE: The re-initialization procedure is not complete if any one of the following conditions occurs before the re-initialization procedure is completed:

- The sunroof switch is not held in the CLOSE position.
- The ignition or battery power is lost.
- The glass panel has not reached its closed position.

NOTE: if the re-initialization procedure is not carried out completely, it must be started over.

(1) Cycle the sunroof to full “VENT” position.

(2) Once the sunroof is in the full “VENT” position, press and continuously hold the “CLOSE” button on the sunroof switch.

(3) After a delay of 10 seconds the sunroof will begin to move past the normal “VENT” position to the **hard stop** position. It will then reverse to the normal “VENT” position also known as the **soft stop**. Once the sunroof has reversed to the **soft stop**, immediately (within 5 seconds of stopping travel) release the “CLOSE” button and continuously press it again.

(4) After a delay of three seconds the sunroof will begin moving to the “OPEN and then “CLOSED position. When the roof reaches the fully “CLOSED” position and stops the close button can be released.

The Re- initialization procedure is now complete. Operate the sunroof in all directions to verify proper operation.

STANDARD PROCEDURE - INITIALIZATION

NOTE: This procedure should be attempted any time a new motor/module is installed in the sunroof assembly. It must be performed on initial vehicle power up to be successful.

NOTE: The initialization procedure is not complete if any one of the following conditions occurs before the initialization procedure is completed:

- The sunroof switch is not held in the CLOSE position.
- The ignition or battery power is lost.

MOTOR/MODULE - SUNROOF (Continued)

- The glass panel has not reached its closed position.

NOTE: if the initialization procedure is not carried out completely, it must be started over.

(1) Turn the ignition key to the “RUN” position.
(2) Continuously press the “CLOSE” button on the sunroof switch.
(3) The sunroof will begin to move past the normal “VENT” position to the **hard stop** position. It will then reverse to the normal “VENT” position also known as the **soft stop**. Once the sunroof has reversed to the **soft stop**, immediately (within 5 seconds of stopping travel) release the “CLOSE” button and continuously press it again.
(4) After a delay of three seconds the sunroof will begin moving to the “OPEN and then “CLOSED position. When the roof reaches the fully “CLOSED” position and stops the close button can be released.

The initialization procedure is now complete. Operate the sunroof in all directions to verify proper operation.

REMOVAL

NOTE: The sunroof system is timed from the factory so that the motor/module shuts off automatically when the sunroof window reaches a certain position. Extreme care must be taken when removing the motor/module from the sunroof assembly or this timing may be thrown off causing damage to the sunroof system. Anytime the motor/module needs to be removed from the sunroof assembly the sunroof window must be in the FULLY CLOSED POSITION if possible.
If glass panel is not in the fully closed position and the motor/module is removed or inoperative, (Refer to 8 - ELECTRICAL/POWER TOP/MOTOR - STANDARD PROCEDURE).

(1) Disconnect and isolate the negative battery cable.
(2) Remove A-pillar trim (Refer to 23 - BODY/INTERIOR/A-PILLAR TRIM - REMOVAL).
(3) Remove sun visors (Refer to 23 - BODY/INTERIOR/SUN VISOR - REMOVAL).
(4) Remove map lamps/mini console, (Refer to 8 - ELECTRICAL/LAMPS/LIGHTING - INTERIOR/READING LAMP - REMOVAL).
(5) Remove the sunroof switch, (Refer to 8 - ELECTRICAL/POWER TOP/SWITCH - REMOVAL).
(6) Remove sunroof opening trim lace. (Refer to 23 - BODY/SUNROOF/OPENING TRIM LACE - REMOVAL).
(7) Remove headliner as necessary to gain access to sunroof motor/module. (Refer to 23 - BODY/INTERIOR/HEADLINER - REMOVAL).
(8) Disconnect the motor/module wire harness connectors.
(9) Remove the motor/module attaching screws.
(10) Remove motor/module from the sunroof housing assembly.

INSTALLATION

NOTE: Before installing a new motor/module or the original motor/module ensure that the sunroof glass panel is in the FULLY CLOSED POSITION. If sunroof glass panel is not in the FULLY CLOSED POSITION, (Refer to 8 - ELECTRICAL/POWER TOP/MOTOR - STANDARD PROCEDURE).

(1) Ensure that sunroof assembly is in the FULLY CLOSED position before mounting the motor/module. If not in the fully closed position (Refer to 8 - ELECTRICAL/POWER TOP/MOTOR - STANDARD PROCEDURE).
(2) Place motor/module into position on the sunroof housing and install attaching screws. Tighten the screws to 3.5 N·m (31 in. lbs.) torque.
(3) Connect the motor/module, and sunroof switch wire connectors.
(4) Install sunroof glass panel (Refer to 23 - BODY/SUNROOF/GLASS PANEL - INSTALLATION).
(5) Connect the battery negative cable.
(6) Perform the motor/module initialization procedure, (Refer to 8 - ELECTRICAL/POWER TOP/MOTOR - STANDARD PROCEDURE - MOTOR/MODULE INITIALIZATION).
(7) Verify sunroof operation and alignment, and adjust as necessary. (Refer to 23 - BODY/SUNROOF/GLASS PANEL - ADJUSTMENTS).
(8) Disconnect and isolate battery negative cable.
(9) Installing the headliner (Refer to 23 - BODY/INTERIOR/HEADLINER - INSTALLATION).
(10) Install sunroof opening trim lace. (Refer to 23 - BODY/SUNROOF/OPENING TRIM LACE - INSTALLATION).
(11) Install the sunroof switch, (Refer to 8 - ELECTRICAL/POWER TOP/SWITCH - INSTALLATION).
(12) Install the map lamps/mini console, (Refer to 8 - ELECTRICAL/LAMPS/LIGHTING - INTERIOR/READING LAMP - INSTALLATION).
(13) Install sun visors (Refer to 23 - BODY/INTERIOR/SUN VISOR - INSTALLATION).
(14) Install A-pillar trim (Refer to 23 - BODY/INTERIOR/A-PILLAR TRIM - INSTALLATION).
(15) Connect the battery negative cable.

SWITCH - SUNROOF

DESCRIPTION

The power sunroof switch is a combination push-button and rocker switch located in the overhead console in between the two reading lamps, (Fig. 1). The switch is mounted in the overhead console with four plastic retaining tabs, molded into the switch housing. The sunroof switch is a direct contact unit that is directly wired to the sunroof motor/module assembly. The sunroof switch performs the following functions:

- Power sunroof open
- Power sunroof auto open
- Power sunroof closed
- Power sunroof vent

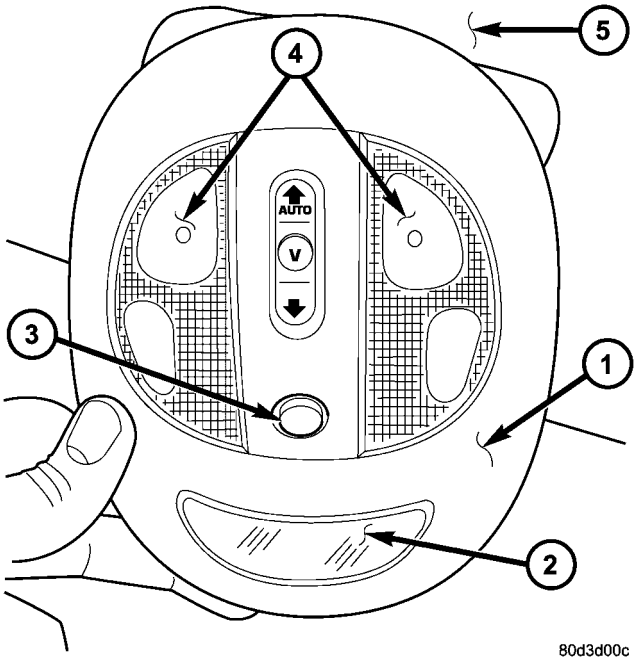

Fig. 1 Overhead Console

1 - OVERHEAD CONSOLE HOUSING
2 - DISPLAY SCREEN
3 - DISPLAY STEP BUTTON
4 - READING/COURTESY LAMPS
5 - HEADLINER

The power sunroof switch cannot be repaired. If the individual components are damaged or inoperative the switch assembly must be replaced, (Refer to 8 - ELECTRICAL/POWER TOP/SWITCH - REMOVAL).

OPERATION

The sunroof is electrically operated from two switches located on the windshield header, rearward of the map lamp. The “VENT” switch is a push button type switch and opens the sunroof to the vent position only. The other switch “OPEN/CLOSED” is a rocker type switch for opening and closing the sunroof. Pressing and releasing the open button once, the sunroof will express open and the wind deflector will raise. If the button is pressed a second time the sunroof will stop in that position. Pressing and holding the close button will close the sunroof. If the close button is released the sunroof will stop in that position.

The switch is grounded at on terminal and receives a 5 volt signal from the sunroof motor/module on the remaining three terminals. The switch pulls down the 5 volt reference voltage from the module signaling it to perform the desired function.

For complete circuit diagrams, refer to the appropriate wiring information. The wiring information includes wiring diagrams, proper wire and connector repair procedures, details of wire harness routing and retention, connector pin-out information and location views for the various wire harness connectors, splices and grounds.

DIAGNOSIS AND TESTING

SUNROOF SWITCH

For complete circuit diagrams, refer to the appropriate wiring information. The wiring information includes wiring diagrams, proper wire and connector repair procedures, details of wire harness routing and retention, connector pin-out information and location views for the various wire harness connectors, splices and grounds.

(1) Remove the power sunroof switch, (Refer to 8 - ELECTRICAL/POWER TOP/SWITCH - REMOVAL).

(2) Disconnect the power sunroof switch wire harness connector.

(3) With the ignition key in the “RUN” position check for 5 volts on the “OPEN”, “CLOSE” and “VENT” circuits of the sunroof switch harness connector. If OK, go to Step 4. If not OK, inspect the wiring harness and connectors between the motor/module and switch for damage and repair as necessary.

(4) With the ignition key in the “OFF” position check for continuity between the ground circuit of the sunroof switch harness connector and a known good ground. Continuity should be present. If OK, go to Step 5. If not OK, inspect the wiring harness and connector and repair the ground circuit as necessary.

(5) Using an ohmmeter, test the continuity of the power sunroof switch (Fig. 2) in each switch position. Refer to the POWER SUNROOF SWITCH CONTINUITY TABLE. If OK, inspect the wiring harness and connectors for damage and repair as necessary. If not OK, replace the power sunroof switch, (Refer to 8 - ELECTRICAL/POWER TOP/SWITCH - REMOVAL).

SWITCH - SUNROOF (Continued)

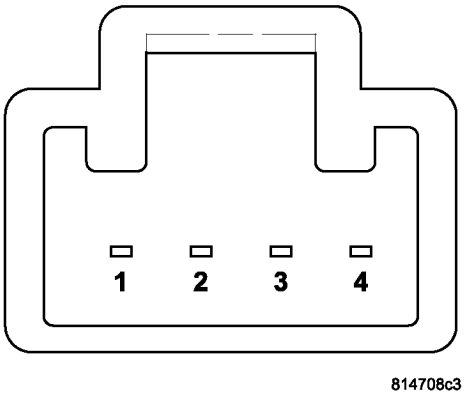

Fig. 2 SUNROOF SWITCH PINOUT

POWER SUNROOF SWITCH CONTINUITY TABLE

SWITCH POSITION	CONTINUITY BETWEEN PINS
OFF	NO CONTINUITY
SUNROOF OPEN	3 & 1
SUNROOF CLOSED	3 & 4
SUNROOF VENT	3 & 2

REMOVAL

(1) Disconnect and isolate the battery negative cable.

(2) Remove the overhead console from the headliner (Refer to 8 - ELECTRICAL/OVERHEAD CONSOLE - REMOVAL).

(3) Disconnect the switch electrical connector.

(4) To remove the switch from the overhead console, push on the back of the switch until it comes free from the overhead console.

INSTALLATION

(1) Install the switch in the overhead console assembly. Be certain the switch is securely snapped in place.

(2) Connect the sunroof control switch electrical connector. Be certain the switch connector is securely snapped in place.

(3) Install the overhead console (Refer to 8 - ELECTRICAL/OVERHEAD CONSOLE - INSTALLATION).

(4) Connect the battery negative cable.

(5) Confirm proper sunroof system operation.

DESCRIPTION 33
OPERATION 33
DIAGNOSIS AND TESTING - WINDOW REGULATOR MODULE 34

POWER WINDOWS

DESCRIPTION

The power window system allows each of the door windows to be raised and lowered electrically by actuating a switch on the instrument panel or center console (sedan only). The front window switch allows the front occupants to lock out the individual rear switches from operation. The power window system receives battery feed through a circuit breaker in the fuse block, only when the ignition switch is in the ON position.

In each door of the convertible there is a window regulator module directly connected to each of the front door window regulator motors. The modules control window motor operation and smart glass functions. The driver window module controls the convertible top operations.

The power window system includes the power window switches on the instrument panel and center console (sedan only), the circuit breaker in the fuse block, and the power window motors.

OPERATION

The front and rear window lift motors are of the permanent magnet type. A battery positive and negative connection to either of the two motor terminals will cause the motor to rotate in one direction. Reversing current through these same two connections will cause the motor to rotate in the opposite direction.

On convertible vehicles, the convertible top switch is hard wired to both window regulator modules by the Power Top Switch Mux circuit. When a top operation input is received by the driver window module, it will ground the respective relay control circuit which in turn will operate the motor. If the convertible top switch is pressed and held to the down position second detent, it will command both modules to drop all windows to the fully down position. The windows cannot be raised when the convertible top switch is in the top down position. When the switch is held in the top up position and all four windows are fully up, the modules will lower the respective front window 40 mm, lower the respective rear window approximately 55 mm and the driver window module will ground the top up relay control circuit. Once the top is back up the windows will not raise automatically.

Each individual motor is grounded through their respective switch.

DIAGNOSIS AND TESTING - POWER WINDOWS

WIRING VOLTAGE TEST

The following wiring test determines whether or not voltage is continuous through the body harness to the front switch.

(1) Remove the power window switch and bezel.

(2) Disconnect wire connector from back of power window switch.

(3) Switch ignition to the ON position.

(4) Connect the clip end of a 12 volt test light to Pin 4 of the window switch harness connector. Touch the test light probe to Pin 3.

- If the test light illuminates, the wiring circuit between the battery and switch is OK.
- If the lamp does not illuminate, first check 30 amp circuit breaker in the fuse block. If circuit breaker is OK, then check for a broken wire.

For complete circuit diagrams, refer to the appropriate wiring information.

POWER WINDOWS (Continued)

POWER WINDOW MOTOR TEST

If the power window motor is receiving proper current and ground and does not operate, proceed with motor test.

For complete circuit diagrams, refer to the appropriate wiring information.

(1) Remove front door trim panel as necessary to gain access to power window motor wire connector.

(2) Disconnect power window motor wire connector from door harness.

(3) Using two jumper wires, connect one to a battery (+) source and the other to a good ground (-).

(4) Connect the Negative (-) jumper probe to one of the motor connector terminals.

(5) Momentarily touch the Positive (+) jumper probe to the other motor connector terminal.

When positive probe is connected the motor should rotate in one direction to either move window up or down. If window is all the way up or down the motor will grunt and the inner door panel will flex when actuated in that one direction.

(6) Reverse jumper probes at the motor connector terminals and window should now move in opposite direction. If window does not move or grunt, replace the motor.

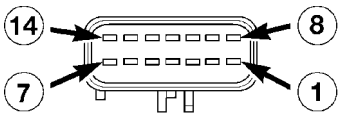
If window moved completely up or down, reverse the jumper probes and cycle window to the opposite position to verify full operation.

If motor grunts and does not move, verify that regulator is not binding.

POWER WINDOW SWITCH

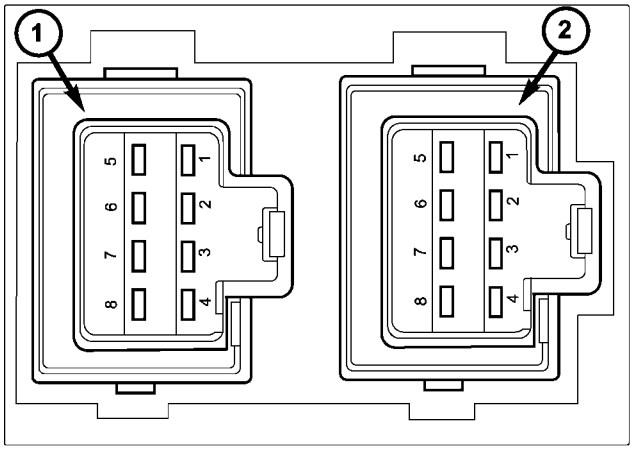
DIAGNOSIS AND TESTING - POWER WINDOW SWITCH

Remove the switch. Using an ohmmeter, test the window switch for continuity in all positions listed in the Continuity Table. Refer to the Power Window Switch Continuity table to determine if continuity is correct (Fig. 1) and (Fig. 2).



80a7e2ba

Fig. 1 FRONT WINDOW SWITCH



80f643a7

Fig. 2 REAR WINDOW SWITCHES

1 - RIGHT REAR SWITCH
2 - LEFT REAR SWITCH

POWER WINDOW SWITCH CONTINUITY TABLE - SEDAN

SWITCH POSITION	CONTINUITY BETWEEN
	FRONT WINDOW SWITCH
LOCKOUT SWITCH (TOP OF SWITCH DEPRESSED)	PIN 12 AND 5
LEFT FRONT UP	PIN 12 AND 14
RIGHT FRONT UP	PIN 12 AND 7
LEFT REAR UP	PIN 12 AND 8
LEFT REAR DOWN	PIN 12 AND 9
RIGHT REAR UP	PIN 12 AND 1
RIGHT REAR DOWN	PIN 12 AND 2
	LEFT OR RIGHT REAR SWITCH
OFF	PIN 2 AND 5 PIN 3 AND 8
UP	PIN 4 AND 5
DOWN	PIN 4 AND 8

To test the left front down and express down switch position, connect pin 4 to ground and pin 12 to a 12 volt source. Using a voltmeter, measure for voltage from pin 13 to ground.

To test the right front down and express down switch position, connect pin 4 to ground and pin 12 to a 12 volt source. Using a voltmeter, measure for voltage from pin 3 to ground. If the correct results are not obtained, replace the switch.

POWER WINDOW SWITCH (Continued)

POWER WINDOW SWITCH CONTINUITY - CONVERTIBLE

SWITCH POSITION	CONTINUITY BETWEEN	RESISTANCE VALUE
NEUTRAL	3 AND 12, 4 AND 12, 5 AND 12, 10 AND 12	4.75K Ω ± 10%
UP - LEFT FRONT	4 AND 12	596 Ω ± 10%

DOWN - LEFT REAR	5 AND 12	338 Ω ± 10%
DOWN - RIGHT FRONT	10 AND 12	338 Ω ± 10%
EXPRESS DOWN - LEFT FRONT	4 AND 12	175 Ω ± 10%
EXPRESS DOWN - RIGHT FRONT	3 AND 12	175 Ω ± 10%

REMOVAL

FRONT

(1) Disconnect and isolate the battery negative cable.

(2) Using a trim stick (special tool #C-4755) or equivalent, gently pry at the top of the switch (Fig. 3).

(3) Remove switch and disconnect electrical harness connector (Fig. 4).

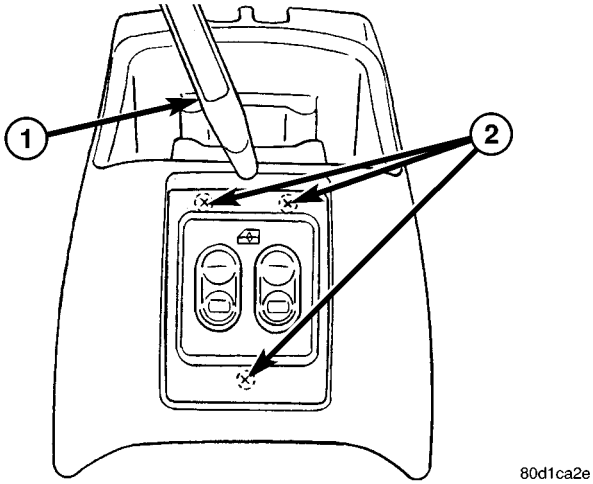

Fig. 3 WINDOW SWITCH REMOVAL (REAR SHOWN - FRONT SIMILAR)

1 - TRIM STICK
2 - RETAINING CLIP LOCATION

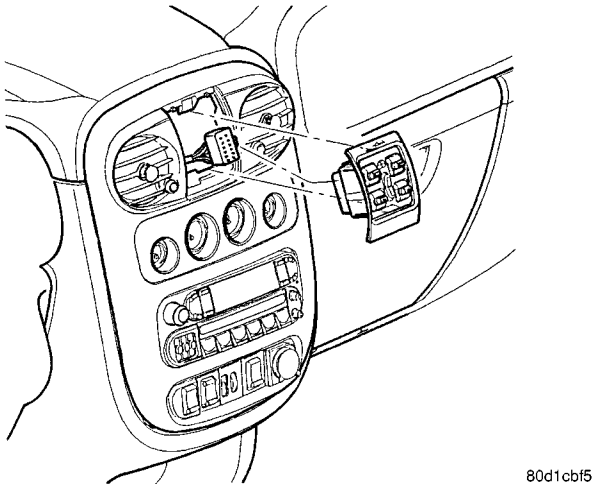

Fig. 4 FRONT WINDOW SWITCH

REAR - SEDAN ONLY

(1) Disconnect and isolate the battery negative cable.

(2) Using a trim stick (special tool #C-4755) or equivalent, gently pry at the top of the switch (Fig. 3).

(3) Remove switch and disconnect electrical harness connectors (Fig. 5).

POWER WINDOW SWITCH (Continued)

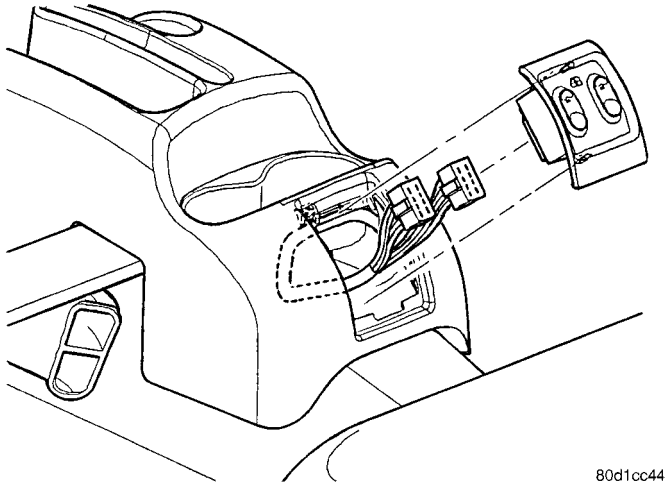

Fig. 5 REAR WINDOW SWITCH - SEDAN ONLY

INSTALLATION

FRONT

(1) Connect electrical harness connector to switch.
(2) Align switch and press into position.
(3) Connect battery negative cable.

REAR - SEDAN ONLY

(1) Connect electrical harness connector to switch.
(2) Align switch and press into position.
(3) Connect battery negative cable.

WINDOW MOTOR

REMOVAL

(1) Move the window to the full UP position position, if possible.

(2) Disconnect and isolate the battery negative cable.

(3) Remove door trim panel (Refer to 23 - BODY/ DOOR - FRONT/TRIM PANEL - REMOVAL).

(4) Disconnect electrical harness connector from motor.

(5) Remove window regulator.

(6) With regulator on bench, remove three screws retaining the motor to the regulator and remove motor.

INSTALLATION

(1) With regulator on bench, install three screws retaining the motor to the regulator.

(2) Install the window regulator.

(3) Connect the electrical harness connector to window motor.

(4) Install door trim panel (Refer to 23 - BODY/ DOOR - FRONT/TRIM PANEL - INSTALLATION).

(5) Connect battery negative cable.

WINDOW REGULATOR MODULE

DESCRIPTION

The window regulator modules are directly connected to each of the front door window regulator motors (Fig. 6). The window switches are hard wired by a mux circuit to the respective window regulator module. The respective rear window motor is hard wired to the module. The front window motor is directly attached to the module. Both front door window switches have the express down feature. The module will cease lowering the front glass when a fully down position is sensed through the hall effect sensor.

When a module must be replaced, it is necessary to replace the entire regulator assembly.

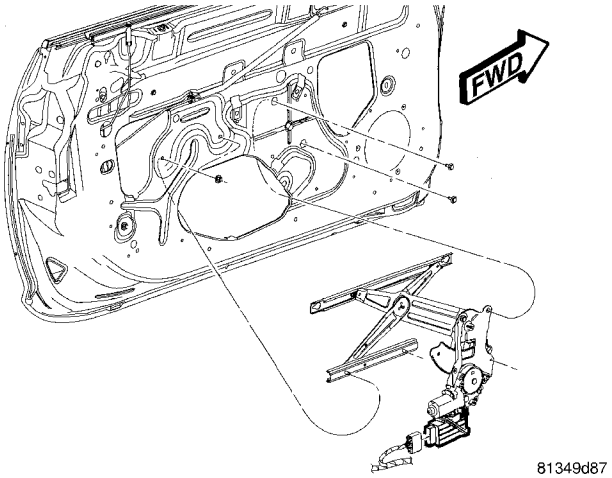

Fig. 6 WINDOW REGULATOR MODULE

OPERATION

When a door is opened, the respective module will receive a signal from the door ajar switch or the window drop switch. The window drop switch is directly controlled by both the interior and the exterior door handle switches. The drop switch is part of the door latch. This switch is faster than the door ajar switch to signal an open door operation. At that point the module will drop the front door glass 10 mm. However, if the window drop switch should fail, the door ajar sense would also drop the window 10 mm and the module would set a trouble code. When the module then receives a door ajar switch open (door closed) it would raise the window 10 mm. The module knows the position of the window by counting the motor rotation through the hall effect sensor in the module. If a door window is raised while that door is open, the module will raise the glass up, but when the door is closed it will raise the glass an additional 10 mm. When the convertible top down switch is

WINDOW REGULATOR MODULE (Continued)

pressed to the first detent, input is received by the driver window regulator module and passenger window regulator module, which will lower the front windows approximately 40 mm, and lower the rear windows approximately 55 mm. After a 200 ms delay, it energizes the power top down relay to lower the convertible top.

DIAGNOSIS AND TESTING - WINDOW REGULATOR MODULE

Any diagnosis of the Window Regulator Modules should begin with the use of the DRB III ® diagnostic tool. For information on the use of the DRB III®, refer to the appropriate Diagnostic Service Information.

For complete circuit diagrams, refer to the appropriate wiring information.

WARNING: DISABLE THE AIRBAG SYSTEM BEFORE ATTEMPTING ANY STEERING WHEEL, STEERING COLUMN, SEAT BELT TENSIONER, SIDE AIRBAG, OR INSTRUMENT PANEL COMPONENT DIAGNOSIS OR SERVICE. DISCONNECT AND ISOLATE THE BATTERY NEGATIVE (GROUND) CABLE, THEN WAIT TWO MINUTES FOR THE AIRBAG SYSTEM CAPACITOR TO DISCHARGE BEFORE PERFORMING FURTHER DIAGNOSIS OR SERVICE. THIS IS THE ONLY SURE WAY TO DISABLE THE AIRBAG SYSTEM. FAILURE TO TAKE THE PROPER PRECAUTIONS COULD RESULT IN ACCIDENTAL AIRBAG DEPLOYMENT AND POSSIBLE PERSONAL INJURY.

DESCRIPTION

FRONT AIRBAG SYSTEM

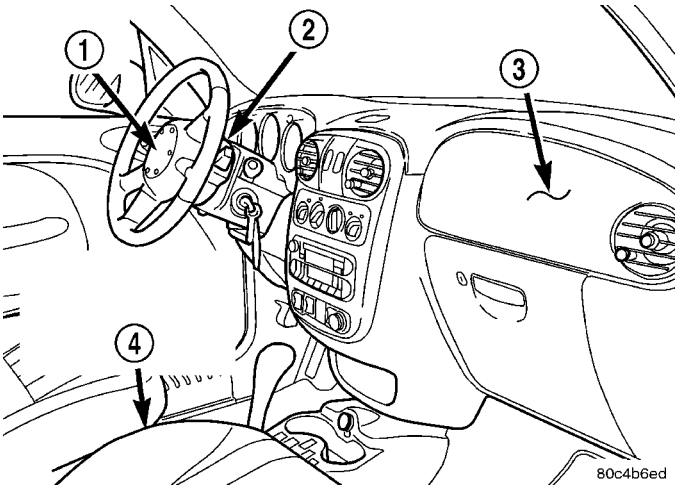

Fig. 1 FRONT AIRBAG SYSTEM COMPONENT LOCATION

1 - DRIVER AIRBAG
2 - CLOCK SPRING
3 - PASSENGER AIRBAG
4 - OCCUPANT RESTRAINT CONTROLLER (ORC)

A dual front airbag system (Fig. 1) utilizes driver and passenger airbags. Both the driver and passenger airbags are certified to new federal regulations, which allows them to deploy with less force than prior airbags. The primary occupant restraints in this vehicle are the seat belts, which require active use by the vehicle occupants. The front airbag system is a supplemental passive restraint that was designed and is intended to enhance the protection for the front seat occupants of the vehicle when used in conjunction with the seat belts.

The driver airbag includes an inflatable airbag and an inflator unit behind a trim cover in the hub area of the steering wheel. The passenger airbag includes an inflatable airbag and an inflator unit behind an airbag door in the instrument panel above the glove box.

The dual front airbag system consists of the following components:

- Occupant Restraint Controller (ORC)
- Airbag indicator lamp.
- Clock Spring
- Driver and passenger airbags (including the airbag inflators).
- Wire harness and connections.

Refer to the proper Body Diagnostic Procedures manual to test or diagnose a problem with any component of the front airbag system.

SIDE IMPACT AIRBAG SYSTEM

The Side Impact Airbag System utilizes two airbags, one mounted to each front seat back frame. This system is designed to enhance protection of occupants in the event of a side impact collision. The ORC supports the Satellite Acceleration Sensors (SAS), Seat Airbags, and an accelerometer that provides verification of the direction and severity of an impact from the both sides.

BELT TENSIONER SYSTEM

The seat belt system incorporates Tensioner Modules. They are integral to the seat belt retractors (Fig. 2) and cannot be serviced. If found defective they must be replaced.

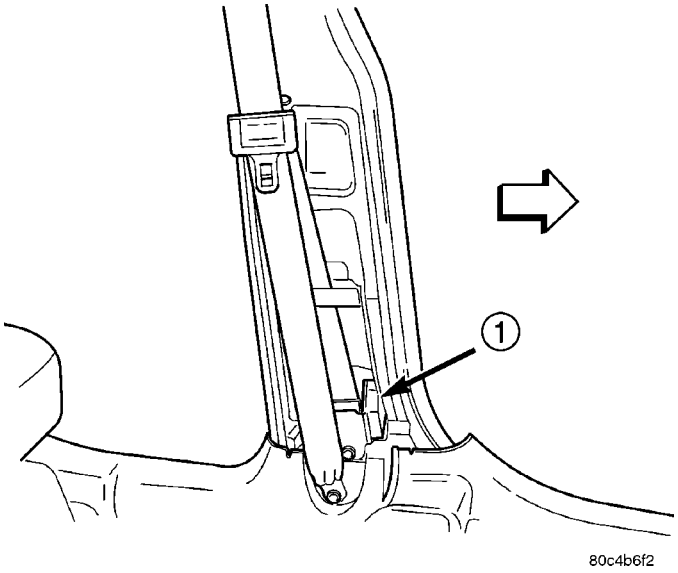

Fig. 2 SEAT BELT TENSIONER LOCATION - TYPICAL

1 - SEAT BELT TENSIONER

OPERATION

FRONT AIRBAG SYSTEM

The front airbag system electrical circuits are continuously monitored by a microprocessor and software contained within the Occupant Restraint Controller (ORC). The ORC also contains impact sensing elements, which are monitored by the ORC to determine when an impact occurs that is severe enough to require front airbag system protection. When a frontal impact is severe enough, the ORC initiates the inflator units of both front airbags to deploy.

An airbag indicator lamp in the instrument cluster lights for six to eight seconds as a bulb test each time the ignition switch is turned to the ON position. Following the bulb test, the airbag indicator lamp is turned ON or OFF by the ORC to indicate the status

RESTRAINTS (Continued)

of the airbag system. If the airbag indicator lamp comes ON at any time other than during the bulb test, it indicates that there is a problem in the airbag system. Such a problem may cause the airbags not to deploy when required, or to deploy when not required.

During a frontal vehicle impact, the knee blockers work in conjunction with properly adjusted seat belts to restrain the driver and front seat passenger in the proper position for an airbag deployment. The knee blockers also work to absorb and distribute the crash energy from the driver and front seat passenger to the structure of the instrument panel. The driver side knee blocker is integral to the lower instrument panel bezel. The passenger side knee blocker is integral to the glove box door.

SIDE IMPACT AIRBAG SYSTEM

The ORC controls the seat back mounted airbags (one left and one right). If a ORC determines the impact is severe enough, based upon a signal from the Satellite Acceleration Sensor (SAS), the ORC will send a signal over the Programmable Communication Interface (PCI date bus and the appropriate airbag will inflate, tearing open the front seat back trim cover protecting the occupants. Once a seat back mounted airbag has been deployed, the entire seat back as well as any damaged parts must be replaced.

BELT TENSIONER SYSTEM

At the onset of an impact event, each tensioner uses a pyrotechnic device which is triggered simultaneously with the airbags to rapidly retract the seat belts. With the slack removed, the occupant's forward motion in an impact will be reduced as will the likelihood of contacting interior components.

WARNING: WHEN THE FRONT AIRBAG IS DEPLOYED, THE TENSIONER WILL HAVE DEPLOYED ALSO, AND MUST BE REPLACED.

The ORC monitors the seat belt tensioner circuit and reports active and stored Diagnostic Trouble Codes (DTC's) if any problem is found.

Once a vehicle has been in an accident, the tensioner will have a "Gravel/Grinding" sound to it after the tensioner has been put into use. This must be replaced along with any deployed airbags and broken or damaged parts.

WARNING

FRONT AIRBAG SYSTEM

This system contains a sensitive, complex electronic unit. Disconnect and isolate the battery negative remote cable before beginning airbag system component removal or installation procedures. This will disable the airbag system. Failure to disconnect the battery could result in accidental airbag deployment, personal injury, or death.

Allow system capacitor to discharge for two minutes before removing airbag components.

Do not place an intact undeployed airbag face down on a solid surface, the airbag will propel into the air if accidentally deployed and could result in personal injury or death. When carrying or handling an undeployed airbag, the trim side of the airbag should be pointing toward the body to minimize possibility of injury or death if accidental deployment occurs.

Replace airbag system components with Mopar® replacement parts only. Substitute parts may appear interchangeable, but internal differences may result in inferior occupant protection, personal injury or death.

Wear safety glasses, rubber gloves, and long sleeved clothing when cleaning powder residue from the vehicle after an airbag deployment. A powder residue emitted from a deployed airbag can cause skin irritation. Flush affected area with cool water if irritation is experienced. If nasal or throat irritation is experienced, exit the vehicle for fresh air until the irritation ceases. If irritation continues, see a physician.

Do not use a replacement airbag that is not in the original packaging, improper deployment, personal injury or death may result.

The factory installed fasteners, screws and bolts used to fasten airbag components have a special coating and are specifically designed for the airbag system. Do not use substitute fasteners, use only original equipment fasteners listed in the parts catalog when fastener replacement is required.

Airbags should be stored in a cool, dry place, away from excessive heat and static electrical activity with the fabric airbag facing up. If not, a premature deployment can result in personal injury or death.

Please refer to the Hazardous Substance Control System for Proper Disposal. Dispose of deployed air bags in a manner consistent with state, provincial, local, and federal regulations.

SIDE IMPACT AIRBAG SYSTEM

The side impact airbag system contains sensitive, complex electronic units. Before attempting to diagnose or service any side impact airbag system components, you must first disconnect and isolate the battery negative (ground) cable. This is the only sure way to dis-

able the side impact airbag system. Failure to do this could result in accidental side impact airbag module deployment and possible personal injury or death.

Allow system capacitor to discharge for two minutes before removing airbag components.

Do not place a nondeployed side airbag face down on a hard surface, the airbag will propel into the air if accidentally deployed, and could result in personal injury or death.

Do not attempt to dismantle a side impact airbag control module (SIACM) or tamper with its inflator. Do not puncture, incinerate, or bring into contact with electricity. Do not store at temperatures exceeding 93° c (200° f).

Replace side impact airbag system components only with parts specified in the Mopar® parts catalog. Substitute parts may appear interchangeable, but internal differences may result in inferior occupant protection.

The fasteners, screws, and bolts originally used for the side impact airbag system components have special coatings and are specifically designed for the side impact airbag system. They must never be replaced with any substitutes. Any time a new fastener is needed, replace it with the correct fasteners provided in the service package or specified in the Mopar® parts catalog.

Deployed and nondeployed airbags may or may not have live pyrotechnic material within the airbag inflator. Do not dispose of driver, passenger, or side airbags unless you are sure of complete deployment. Please refer to the hazardous substance control system for proper disposal. Dispose of deployed airbags in a manner consistent with state, provincial, local, and federal regulations.

LOWER ANCHOR AND TETHER FOR CHILDREN

During, and following, any child restraint anchor service, due to an impact event or vehicle repair, carefully inspect all mounting hardware, tether straps, and anchors for proper installation, operation, or damage. If a child restraint anchor is found damaged in any way, the anchor must be replaced.

DIAGNOSIS AND TESTING - AIRBAG SYSTEM

(1) With the battery negative remote cable disconnected, connect the scan tool to the Data Link Connector (DLC).

(2) Turn the ignition key to the ON position, then exit vehicle with the scan tool.

(3) After checking that no one is inside the vehicle, connect the battery negative remote terminal.

(4) Read and record the **ACTIVE** Diagnostic Trouble Code (DTC) data.

(5) Read and record any **STORED** DTC's.

(6) Refer to the proper diagnostic information if any DTC's are found in Step 4 and Step 5.

(7) If the airbag warning lamp either fails to light, or goes ON and stays ON, there is a system malfunction. To test the airbag warning lamp (bulb) operation in the cluster (Refer to 8 - ELECTRICAL/ INSTRUMENT CLUSTER - DIAGNOSIS AND TESTING). Refer to the proper diagnostic information for any other system problems.

STANDARD PROCEDURE

STANDARD PROCEDURE - HANDLING AIRBAGS

DEPLOYED AIRBAG

The vehicle interior may contain a very small amount of sodium hydroxide powder, a by-product of airbag deployment. Sodium hydroxide powder can irritate the skin, eyes, nose and throat. Wear safety glasses, rubber gloves, and long sleeved clothing when cleaning any of the powder residue from the vehicle.

If you find that the cleanup is irritating your skin, run cool water over the affected area. Also, if you experience nasal or throat irritation, exit the vehicle for fresh air until the irritation ceases. If irritation continues, see a physician.

UNDEPLOYED AIRBAG

The airbags must be stored in its original special container until used for service. At no time should a source of electricity be permitted near the inflator on the back of an airbag. When carrying or handling an undeployed airbag, the trim side of the airbag should be pointing toward the body to minimize possibility of injury if accidental deployment occurs. Do not place undeployed airbag face down on a solid surface, the airbag will propel into the air if accidental deployment occurs.

STANDARD PROCEDURE - SERVICE AFTER AN AIRBAG DEPLOYMENT

DRIVER AIRBAG

After a Driver Airbag has been deployed due to a collision, the following **MUST** be replaced:

- Driver Airbag
- Clockspring Assembly
- Steering Wheel
- Complete Steering Column Assembly with Lower Steering Column Coupler

RESTRAINTS (Continued)

All other airbag and vehicle components should be closely inspected following any airbag deployment, and should be replaced when visible damage is incurred.

WARNING: Do not connect the battery negative cable (Refer to 8 - ELECTRICAL/RESTRAINTS - DIAGNOSIS AND TESTING - AIRBAG SYSTEM). Personal injury or death may result if the system test is not performed first.

PASSENGER AIRBAG

After a Passenger Airbag has been deployed due to a collision. the following **MUST** be replaced:

- Passenger Airbag
- Passenger Airbag Cover

All other airbag and vehicle components should be closely inspected following any airbag deployment, and should be replaced when visible damage is incurred.

WARNING: Do not connect the battery negative cable (Refer to 8 - ELECTRICAL/RESTRAINTS - DIAGNOSIS AND TESTING - AIRBAG SYSTEM). Personal injury or death may result if the system test is not performed first.

SEAT AIRBAG

After a Seat Airbag has been deployed due to a collision. the following **MUST** be replaced:

- Complete Seat Back Assembly

All other airbag and vehicle components should be closely inspected following any airbag deployment, and should be replaced when visible damage is incurred.

WARNING: Do not connect the battery negative cable (Refer to 8 - ELECTRICAL/RESTRAINTS - DIAGNOSIS AND TESTING - AIRBAG SYSTEM). Personal injury or death may result if the system test is not performed first.

SEAT BELTS AND TENSIONERS

After a frontal impact where an airbag has been deployed due to a collision. the following **MUST** be replaced:

- Front Seat Belt Retractors (driver and passenger) with integral Tensioners.

All other seat belts should be closely inspected for cuts, tears, fraying, or damage in any way following any frontal impact or airbag deployment. The other seat belts are to be replaced when visible damage is incurred. Inspect the Lower Anchors and Tether for CHildren (LATCH) child restraint anchors for damage after an impact event and replace as needed.

WARNING: Do not connect the battery negative cable (Refer to 8 - ELECTRICAL/RESTRAINTS - DIAGNOSIS AND TESTING - AIRBAG SYSTEM). Personal injury or death may result if the system test is not performed first.

CLEAN UP PROCEDURE

Roll or fold the airbag towards its mounting point (i.e. instrument panel, steering wheel, or seat back). Then tape the ripped cover over the deployed airbag.

Use a vacuum cleaner to remove any residual powder from the vehicle interior. Work from the outside in to avoid kneeling or sitting in a contaminated area. Vacuum the heater and A/C outlets as well (Fig. 3). If the heater or air conditioner was in RECIRC mode at time of airbag deployment, operate blower motor on low speed and vacuum powder residue expelled from the heater and A/C outlets. Multiple vacuum cleaning may be necessary to decontaminate the interior of the vehicle.

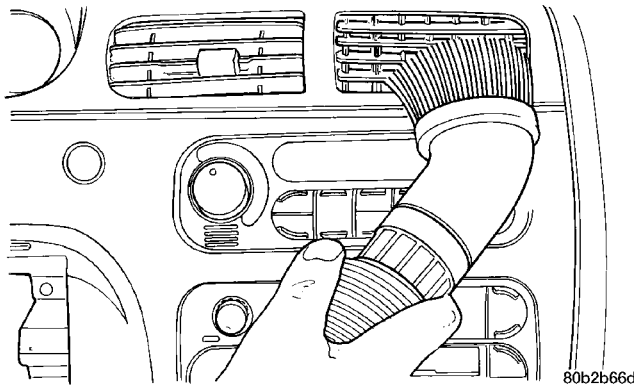

Fig. 3 VACUUM HEATER AND A/C OUTLETS - TYPICAL

CHILD RESTRAINT ANCHOR

DESCRIPTION

The Lower Anchors and Tether for CHildren, or LATCH child restraint anchorage system provides for the installation of suitable child restraints in certain seating positions without using the seat belt provided for that seating position. The second row seats are equipped with a fixed-position child restraint upper tether anchor for both the outboard seating positions (Fig. 4), and child restraint lower anchors for both outboard seating positions (Fig. 5).

The lower anchors are permanently mounted on the second row seat frames. These anchors are also constructed from a heavy-gauge steel wire loop welded to the frame. They are each accessed from the front of their respective seats, at each side where the

CHILD RESTRAINT ANCHOR (Continued)

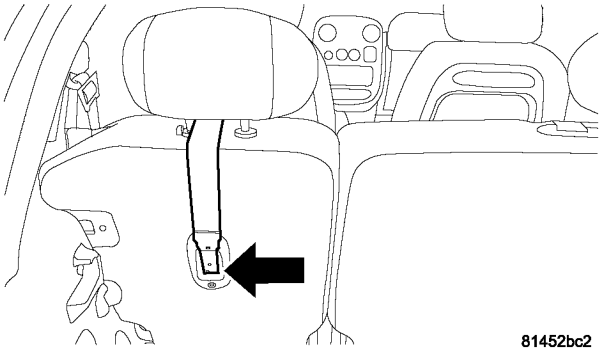

Fig. 4 UPPER TETHER ANCHOR

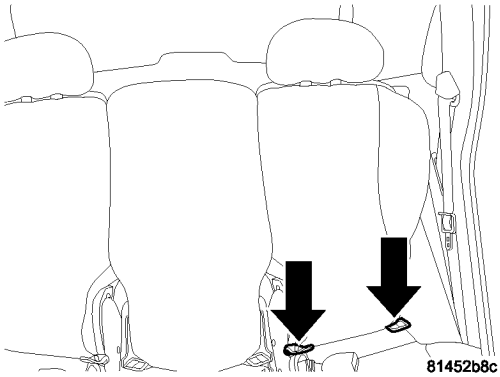

Fig. 5 LOWER CHILD RESTRAINT ANCHORS

seat back meets the seat cushion (Fig. 5). These lower anchors cannot be adjusted or repaired and, if faulty or damaged, the entire seat frame must be replaced.

OPERATION

See the owner's manual in the vehicle glove box for more information on the proper use of all of the factory-installed child restraint anchors.

CHILD RESTRAINT ANCHOR - PT27

DESCRIPTION

This model is equipped with a Lower Anchors and Tether for CHildren, or LATCH child restraint anchorage system (Fig. 6). The LATCH system provides for the installation of suitable child restraints in certain seating positions without using the standard equipment seat belt provided for that seating position. The rear seats are equipped with a fixed-position child restraint upper tether anchor for both the two outboard seating positions, and child restraint lower anchors for the two outboard seating positions only.

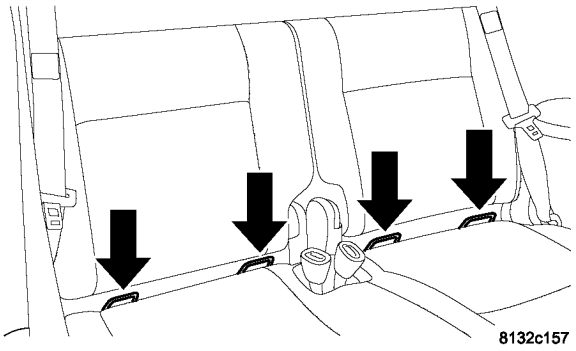

Fig. 6 LOWER CHILD RESTRAINT ANCHORS

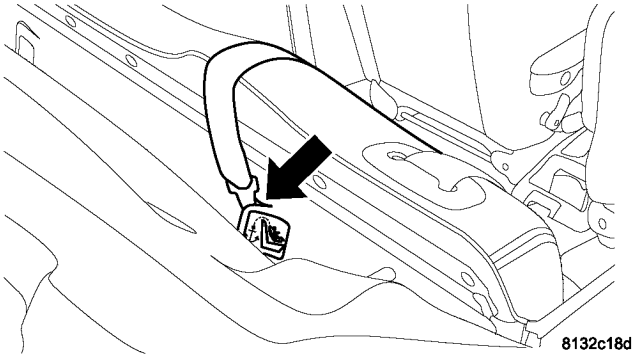

Fig. 7 UPPER TETHER STRAP ANCHOR

The two upper tether anchors are integral to the rear seat back attachment panel (Fig. 7). There is a separate molded plastic trim bezel located around each of the two anchors. The child restraint upper tether anchors cannot be adjusted or repaired and, if faulty or damaged, they must be replaced with the rear seat back attachment panel.

OPERATION

See the owner's manual in the vehicle glove box for more information on the proper use of all of the factory-installed child restraint anchors.

CLOCKSPRING

DESCRIPTION

The clockspring is mounted to the steering column behind the steering wheel (Fig. 8). This assembly consists of a flat, ribbon like, electrically conductive tape that winds and unwinds with the steering wheel rotation. The clockspring is used to maintain a continuous electrical circuit between the wiring harness and the:

- Driver Airbag.
- Speed Control Switch.
- Horn Switch.

CLOCKSPRING (Continued)

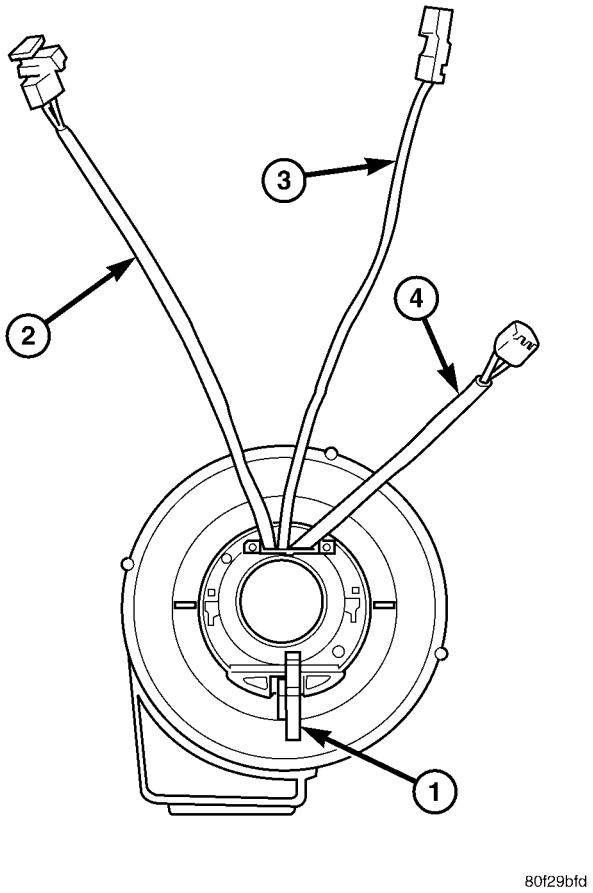

Fig. 8 CLOCKSPRING

1 - LOCKING PIN
2 - DRIVER AIRBAG WIRE/CONNECTOR
3 - HORN WIRE/CONNECTOR
4 - SPEED CONTROL WIRE/CONNECTOR

OPERATION

The clockspring is used to maintain a continuous electrical circuit between the wiring harness and the driver airbag.

The clockspring must be properly centered when it is installed on the steering column following any service removal, or it will be damaged (Refer to 8 - ELECTRICAL/RESTRAINTS/CLOCKSPRING - STANDARD PROCEDURE).

The clockspring cannot be repaired. If the clock spring is faulty, damaged, or if the airbag has been deployed, the clockspring must be replaced.

STANDARD PROCEDURE - CLOCKSPRING CENTERING

If the rotating tape within the clockspring is not positioned properly with the steering wheel and the front wheels, the clockspring may fail during use. The following procedure **MUST BE USED** to center the clockspring if:

- The clockspring is not known to be properly positioned.
- The front wheels were moved.
- The steering wheel was moved from the half turn (180 degrees) to the right (clockwise) position.

(1) Open hood.

(2) Disconnect and isolate the battery negative cable.

WARNING: Wait two minutes for the airbag system reserve capacitor to discharge before beginning any airbag system or component service. Failure to do so may result in accidental airbag deployment, personal injury or death.

(3) Remove clockspring (Refer to 8 - ELECTRICAL/RESTRAINTS/CLOCKSPRING - REMOVAL).

(4) Rotate the clockspring rotor in the CLOCKWISE DIRECTION to the end of travel. Do not apply excessive torque.

(5) From the end of travel, rotate the rotor three full turns in the counterclockwise direction. The horn wire and the squib wire should end up at the bottom. If not, rotate the rotor counter clockwise until the wires are properly oriented, but not more than half turn (180 degrees). Engage clockspring locking mechanism.

(6) Install the clockspring (Refer to 8 - ELECTRICAL/RESTRAINTS/CLOCKSPRING - INSTALLATION).

WARNING: Do not connect the battery negative cable (Refer to 8 - ELECTRICAL/RESTRAINTS - DIAGNOSIS AND TESTING - AIRBAG SYSTEM). Personal injury or death may result if the system test is not performed first.

(7) Close hood.

(8) Verify vehicle and system operation.

REMOVAL

(1) Place the front road wheels in the straight ahead position. Then:

- Rotate the steering wheel half turn (180 degrees) to the right (clockwise).
- Lock column with ignition lock cylinder.

(2) Open hood.

(3) Disconnect and isolate the battery negative cable.

(4)

WARNING: Wait two minutes for the airbag system reserve capacitor to discharge before beginning any airbag system or component service. Failure to do so may result in accidental airbag deployment, personal injury or death.

CLOCKSPRING (Continued)

(5) Remove steering wheel (Refer to 19 - STEERING/COLUMN/STEERING WHEEL - REMOVAL).

(6) Remove upper and lower steering column shrouds to gain access to clockspring wiring (Refer to 19 - STEERING/COLUMN/UPPER SHROUD - REMOVAL).

(7) Remove multi-function switch (Refer to 8 - ELECTRICAL/LAMPS/LIGHTING - EXTERIOR/ MULTI-FUNCTION SWITCH - REMOVAL).

(8) Disconnect the 7-way connector between the clockspring and the instrument panel wiring harness at the base of the clock spring.

(9) Remove clockspring by lifting the top latch tab up slightly to guide it over the lock housing (Fig. 9). The clockspring cannot be repaired, and must be replaced if faulty.

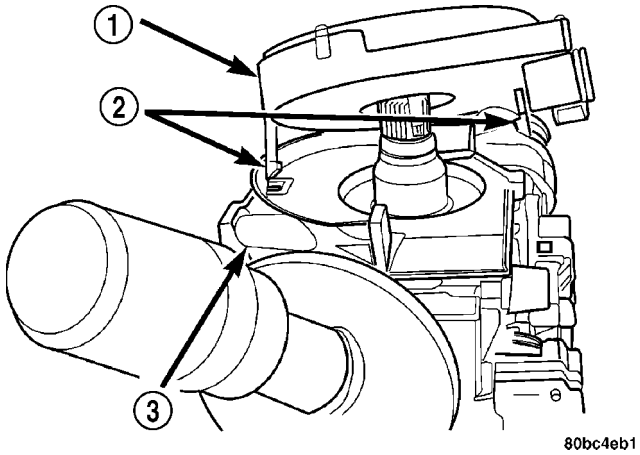

Fig. 9 CLOCKSPRING LATCH HOOKS

1 - CLOCKSPRING
2 - LATCH HOOKS
3 - STEERING COLUMN

(10) Rotate clockspring rotor a half turn (180 degrees) to the left (counter clockwise).

(11) Lock the clockspring rotor in the center position as follows: Insert a paper clip wire through the hole in the rotor at the 10 o'clock position and bend to prevent it from falling out.

INSTALLATION

(1) Confirm that:

- The steering wheel position is a half turn (180 degrees) to the right (clockwise)
- The column is locked with the ignition cylinder lock.
- Check that the turn signal stalk is in the neutral position
- When reusing the clockspring, remove locking wire and rotate clockspring rotor one half turn (180 degrees) to the right (clockwise). Locate the clockspring on the steering shaft and push down on the rotor until the clockspring is fully seated on the steering column (Fig. 9).
- When installing a new clockspring, position the front wheels straight a head. Remove grenade pin.

(2) Connect the clockspring to the instrument panel harness, ensure wiring is properly routed. Then check that the connectors, locking tabs are properly engaged and the halo lamp wire is in position.

(3) Install steering column shrouds (Refer to 19 - STEERING/COLUMN/UPPER SHROUD - INSTALLATION). Be sure all wires are inside of shrouds.

(4) Install steering wheel ensuring the flats on hub align with the clockspring (Refer to 19 - STEERING/ COLUMN/STEERING WHEEL - INSTALLATION). Pull the horn, airbag and speed control leads through the larger slot. Ensure leads do not get pinched under the steering wheel.

(5) Route speed control wires under and behind the driver airbag mounting tabs.

(6) Connect the speed control wires to the switch.

(7) Connect the horn lead wire and the driver airbag lead wire to the airbag.

(8) Install the driver airbag.

WARNING: Do not connect the battery negative cable (Refer to 8 - ELECTRICAL/RESTRAINTS - DIAGNOSIS AND TESTING - AIRBAG SYSTEM). Personal injury or death may result if the system test is not performed first.

(9) Close hood.

(10) Verify vehicle and system operation.

DRIVER AIRBAG

DESCRIPTION

The driver airbag protective trim cover is the most visible part of the driver airbag system (Fig. 10). The driver airbag is mounted directly to the steering wheel. Located under the airbag cover are the horn switch, the folded airbag cushion, and the airbag cushion supporting components (Fig. 11). The resistive membrane-type horn switch is secured within a pocket on the airbag cushion.

The driver airbag cannot be repaired and must be replaced if deployed or in any way damaged. The driver airbag cover is available for service replacement if marred, scratched, or disfigured. The horn switch is not serviceable and if found faulty or defective, a complete driver airbag assembly will need to be installed.

DRIVER AIRBAG (Continued)

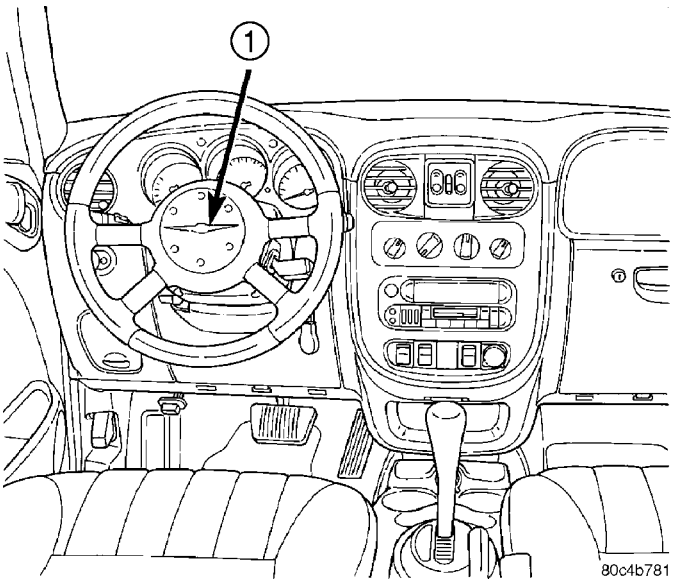

Fig. 10 DRIVER AIRBAG LOCATION

1 - DRIVER AIRBAG

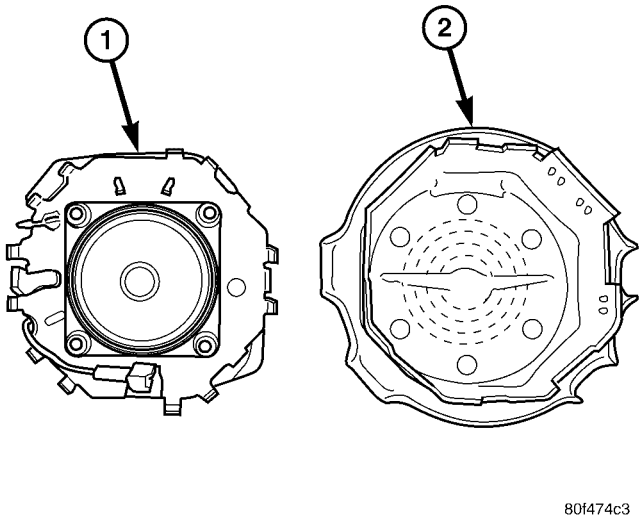

Fig. 11 DRIVER AIRBAG AND COVER

1 - DRIVER AIRBAG
2 - DRIVER AIRBAG COVER

OPERATION

The driver airbag includes a stamped metal housing to which the cushion and an inflator unit are attached and sealed. The conventional pyrotechnic-type inflator assembly is mounted to studs on the back of the airbag housing. The inflator seals the hole in the airbag cushion so it can discharge the gas it produces directly into the cushion when supplied with the proper electrical signal. Following an airbag deployment, the airbag cushion quickly deflates by venting this gas towards the instrument panel through the porous fabric material used on the steering wheel side of the airbag cushion.

The protective trim cover is fitted to the front of the airbag and forms a decorative cover in the center of the steering wheel. The inside of the trim cover has locking blocks molded into it that engage a lip on the airbag metal housing. Two stamped metal retainers then fit over the inflator mounting studs on the back of the airbag housing and are engaged in slots on the inside of the cover, securely locking the trim cover into place. The trim cover will split at predetermined breakout lines, then fold back out of the way along with the horn switch and tray unit upon airbag deployment.

REMOVAL

(1) Open hood.

(2) Disconnect and isolate the battery negative cable.

(3) Wait two minutes for the system reserve capacitor to discharge before servicing any airbag components.

(4) Remove upper and lower steering column shrouds to gain access to clock spring wiring (Refer to 19 - STEERING/COLUMN/UPPER SHROUD - REMOVAL).

(5) Using a pair of 90° internal snap ring pliers or equivalent, pry open the retaining clip (Fig. 12) on the back of the steering wheel to release the retaining pin (Fig. 13). Pull or press rearward on the driver airbag while doing this. The pin will release slightly.

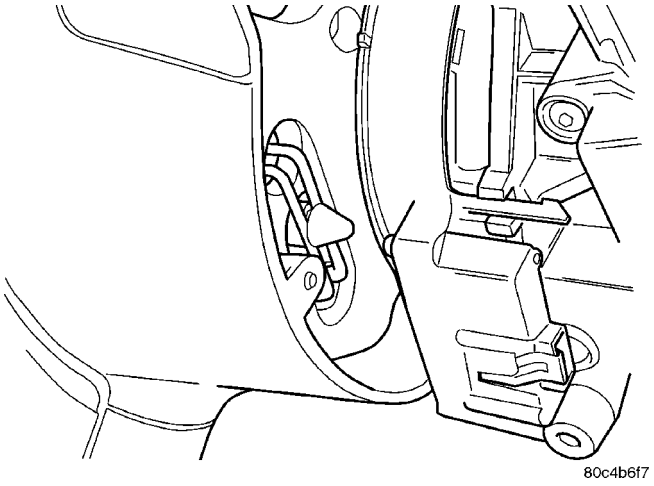

Fig. 12 DRIVER AIRBAG RETAINING PIN

(6) Using a pair of 90° internal snap ring pliers or equivalent, pry open the retaining clip (Fig. 14), and at the same time gently pry the pin away from the retaining clip, using a pocket screwdriver or equivalent, so it can slide through the middle of the clip. Use the screwdriver to push the pin through the clip.

(7) When the driver airbag releases from the steering wheel, peel rearward and expose the underside of

DRIVER AIRBAG (Continued)

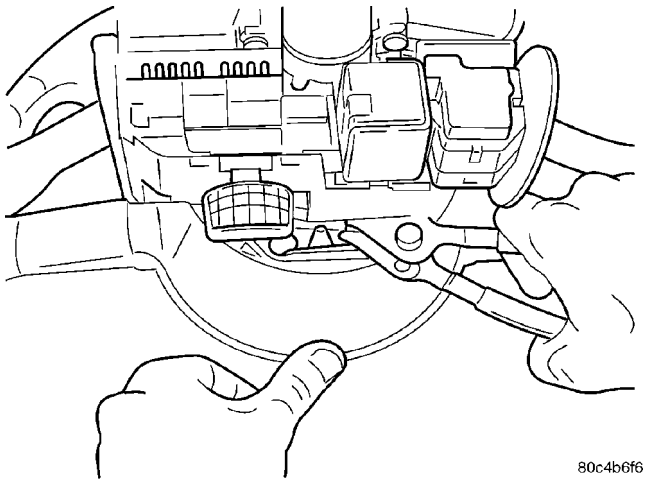

Fig. 13 FIRST DRIVER AIRBAG RETAINING PIN - REMOVAL

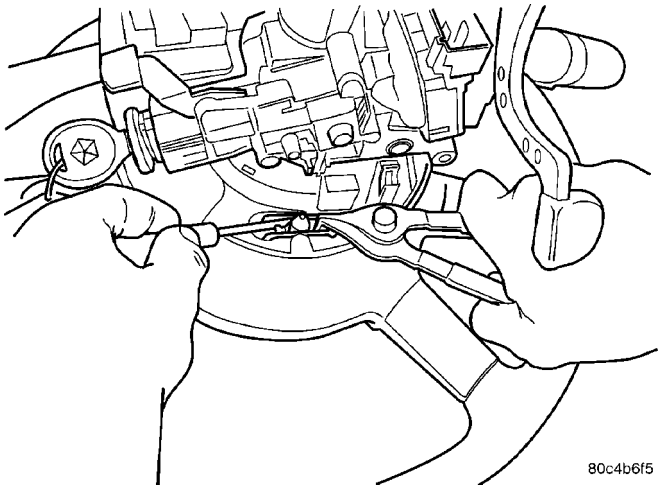

Fig. 14 SECOND DRIVER AIRBAG RETAINING PIN - REMOVAL

the airbag. Disconnect the two harness connectors, squib and horn feed (Fig. 15) and (Fig. 16). Use a small pocket screwdriver to separate horn connector. Insert into the bottom of the connector (airbag side) and pull handle of screwdriver up while pulling out on the clock spring side of the connector.

(8) Remove airbag from vehicle.

WARNING: WHEN REPLACING A DEPLOYED DRIVER AIRBAG, THE CLOCK SPRING MUST ALSO BE REPLACED (Refer to 8 - ELECTRICAL/RESTRAINTS/CLOCK SPRING - REMOVAL).

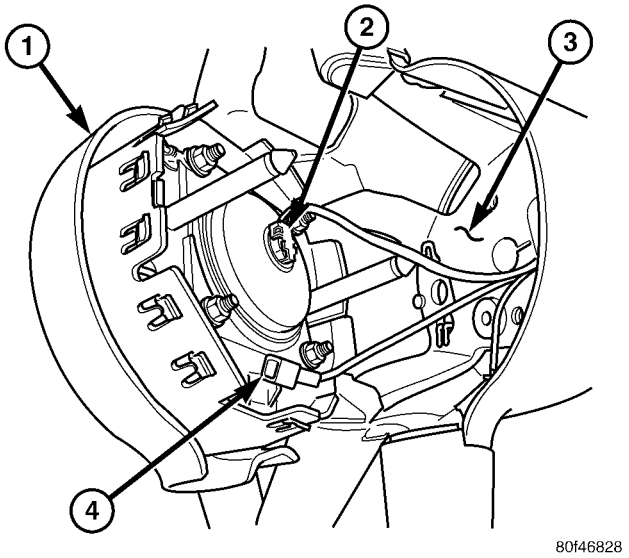

Fig. 15 DRIVER AIRBAG ELECTRICAL CONNECTORS

1 - DRIVER AIRBAG
2 - DRIVER AIRBAG SQUIB CONNECTOR
3 - STEERING WHEEL
4 - HORN CONNECTOR

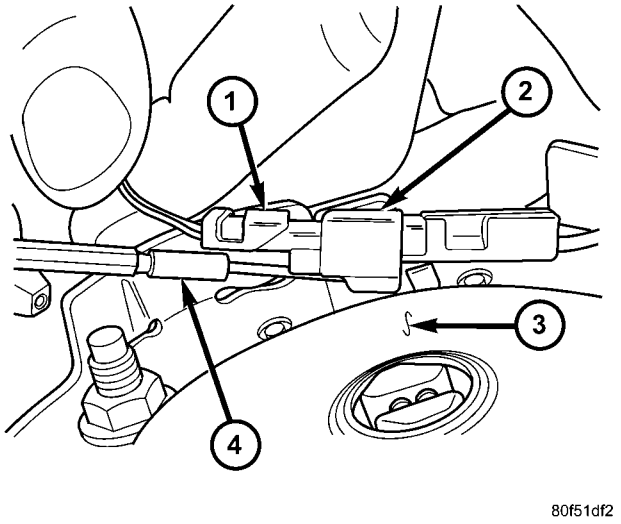

Fig. 16 DRIVER AIRBAG HORN CONNECTOR

1 - WIRE FROM CLOCK SPRING
2 - WIRE TO HORN SWITCH
3 - DRIVER AIRBAG IGNITER
4 - SMALL SCREWDRIVER

DRIVER AIRBAG (Continued)

INSTALLATION

NOTE: Before installation, inspect the rear of the steering wheel for presence of driver airbag retaining clips anti-rattle foam pads. If any of them are damaged or missing, replace them as necessary.

(1) Connect the squib wire to the driver airbag. Make airbag connection by pressing straight in on the connector. The connector should be fully seated. Feel for positive snap to assure positive connection.

(2) Connect the horn wire.

(3) **Rotate the steering wheel 90° left or right.**

(4) Place driver airbag into position and firmly snap both pins into place. **Listen for the audible click at each pin. Visually check that both pins are properly seated between the legs of the clips.**

(5) Install steering column shrouds (Refer to 19 - STEERING/COLUMN/UPPER SHROUD - INSTALLATION). Be sure all wires are inside of shrouds.

WARNING: DO NOT CONNECT BATTERY NEGATIVE CABLE YET (Refer to 8 - ELECTRICAL/RESTRAINTS - DIAGNOSIS AND TESTING - AIRBAG SYSTEM).

(6) Close hood.

(7) Verify vehicle and system operation.

DRIVER AIRBAG COVER

REMOVAL

(1) Open hood.

(2) Disconnect and isolate the battery negative cable.

(3) Wait two minutes for the system reserve capacitor to discharge before servicing any airbag components.

(4) Remove the driver airbag (Refer to 8 - ELECTRICAL/RESTRAINTS/DRIVER AIRBAG - REMOVAL).

(5) With driver airbag removed, pick a corner and push down on the inflator or latch hook mounting plate until the latch hooks push out of the driver airbag cover (Fig. 17). On two of the latch hook locations, there is a tab on top of the latch hooks that retains the DAB. Before pushing down on the latch hook plate, pull up on the DAB mounting pins and push a small screwdriver between the tab and the DAB cover. Then continue with normal removal.

(6) Remove driver airbag from driver airbag cover (Fig. 18).

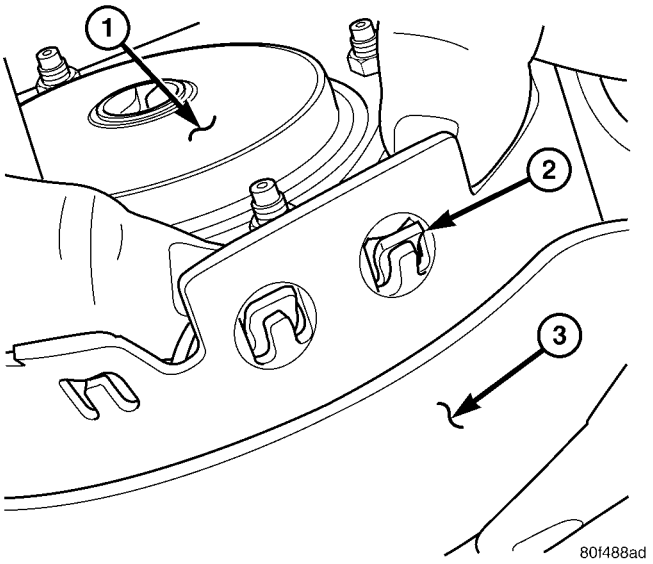

Fig. 17 UNLATCH DRIVER AIRBAG COVER

1 - INFLATOR OR LATCH HOOK MOUNTING PLATE
2 - LATCH HOOK
3 - DRIVER AIRBAG COVER

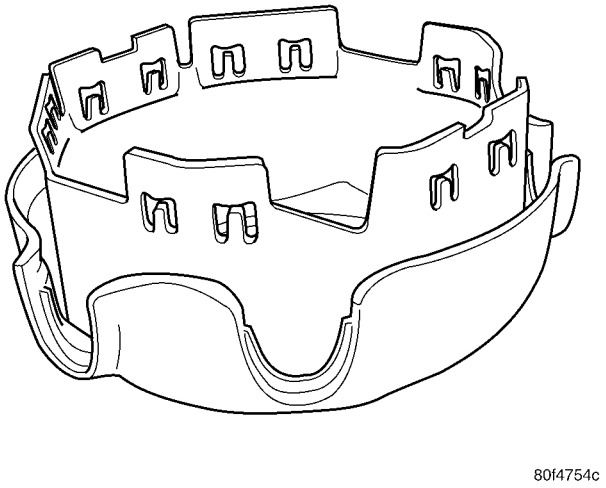

Fig. 18 DRIVER AIRBAG COVER

INSTALLATION

(1) Place driver airbag into new driver airbag cover. Be careful not to pinch airbag cushion between latch hook mounting plate and cover.

(2) Push down on the latch hook mounting plate and guide the latch hooks into the slots on the driver airbag cover.

(3) Once all the latch hooks have been started, pull the driver airbag cover away from the driver airbag to fully seat the latch hooks (Fig. 19).

DRIVER AIRBAG COVER (Continued)

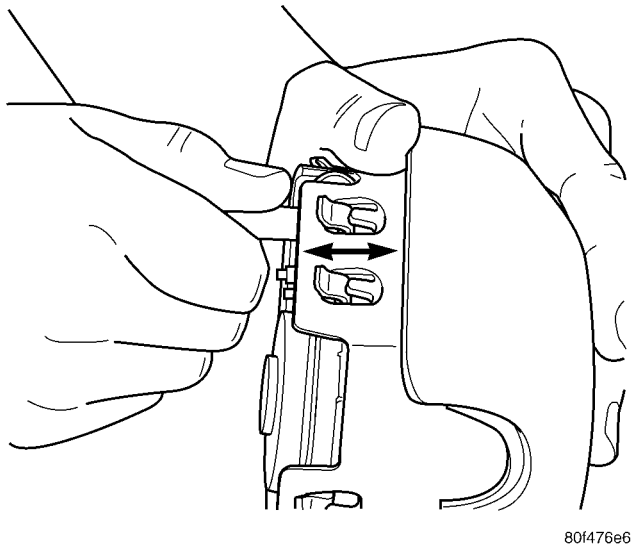

Fig. 19 SECURE DRIVER AIRBAG COVER LATCH HOOKS

(4) Install the driver airbag (Refer to 8 - ELECTRICAL/RESTRAINTS/DRIVER AIRBAG - INSTALLATION).

FRONT SEAT BELT & RETRACTOR

REMOVAL

WARNING: FRONT SEAT BELT ASSEMBLIES MUST BE REPLACED AFTER A COLLISION.

(1) Disconnect and isolate the battery negative cable.
(2) Wait two minutes for the system reserve capacitor to discharge before servicing any airbag components.
(3) Remove plastic turning loop cover.
(4) Remove shoulder belt height control knob.
(5) Remove bolt attaching turning loop to belt adjuster.
(6) Remove upper B-pillar trim (Refer to 23 - BODY/INTERIOR/B-PILLAR TRIM - REMOVAL).
(7) Remove access cover from B-pillar trim.
(8) Remove anchor bolt from lower B-pillar.
(9) Disengage clips attaching trim to B-pillar.
(10) Feed seat belt turning loop and seat belt through trim panel.
(11) Disconnect electrical connector.
(12) Remove the webbing mid guide two screws.
(13) Remove lower B-pillar trim from vehicle.
(14) Remove front seat belt retractor.

INSTALLATION

WARNING: FRONT SEAT BELT ASSEMBLIES MUST BE REPLACED AFTER A COLLISION.

NOTE: Tighten all seat belt bolts to 40 N·m (30 ft. lbs.) torque.

(1) Place front seat belt retractor into position.
(2) Position lower B-pillar trim panel near B-pillar (Refer to 23 - BODY/INTERIOR/B-PILLAR TRIM - INSTALLATION).
(3) Install the two screws to the webbing mid guide.
(4) Connect electrical connector.
(5) Feed seat belt turning loop and seat belt through trim panel.
(6) Align locating pins on backside of trim panel to mating holes in B-pillar.
(7) Push clips on trim panel into slots in B-pillar.
(8) Install access cover to B-pillar trim.
(9) Install bolt attaching lower seat belt anchor to floor pan kick-up.
(10) Install bolt attaching turning loop to belt adjuster.
(11) Move height adjuster to the lowest position.
(12) Install upper B-pillar trim.
(13) Install shoulder belt height control knob.
(14) Install the plastic turning loop cover.

WARNING: DO NOT CONNECT BATTERY NEGATIVE CABLE YET (Refer to 8 - ELECTRICAL/RESTRAINTS - DIAGNOSIS AND TESTING - AIRBAG SYSTEM).

FRONT SEAT BELT & RETRACTOR - PT27

REMOVAL

(1) Release hood latch and open hood.
(2) Disconnect and isolate the battery negative cable.

WARNING: Wait two minutes for the airbag system reserve capacitor to discharge before beginning any airbag system or component service. Failure to do so may result in accidental airbag deployment, personal injury or death.

(3) Remove the seat belt from within the seat belt web guide (Fig. 20).
(4) Remove the seat belt anchor bolt (Fig. 21).
(5) Remove the upper turning loop retaining bolt (Fig. 21).
(6) Remove the Lower Quarter Trim Panel.

FRONT SEAT BELT & RETRACTOR - PT27 (Continued)

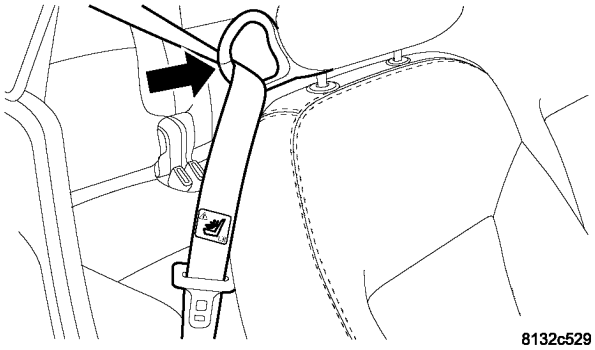

Fig. 20 SEAT BELT WEB GUIDE

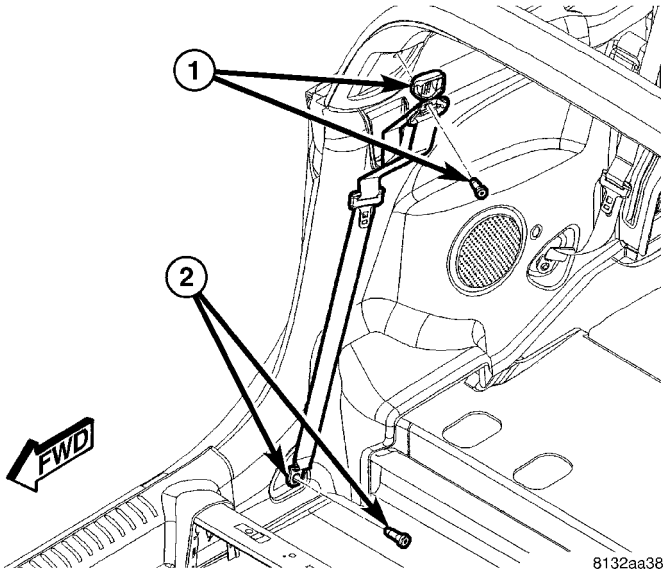

Fig. 21 LOWER ANCHOR BOLT

1 - JUPPER TURNING LOOP RETAINING BOLT
2 - LOWER ANCHOR BOLT

(7) Disconnect the tensioner squib connector (Fig. 22).

(8) Remove the one bolt to the front seat belt retractor (Fig. 23).

(9) Remove retractor from vehicle.

INSTALLATION

(1) Position retractor in vehicle.

(2) Install the one bolt to the front seat belt retractor (Fig. 23). Torque bolt to 40 N·m (30 ft. lbs.).

(3) Connect the tensioner squib connector (Fig. 22).

(4) Install the Lower Quarter Trim Panel.

(5) Install the upper turning loop retaining bolt (Fig. 21). Torque bolt to 40 N·m (30 ft. lbs.).

(6) Install the seat belt anchor bolt (Fig. 21). Torque bolt to 40 N·m (30 ft. lbs.).

(7) Route the seat belt within the seat belt web guide (Fig. 20).

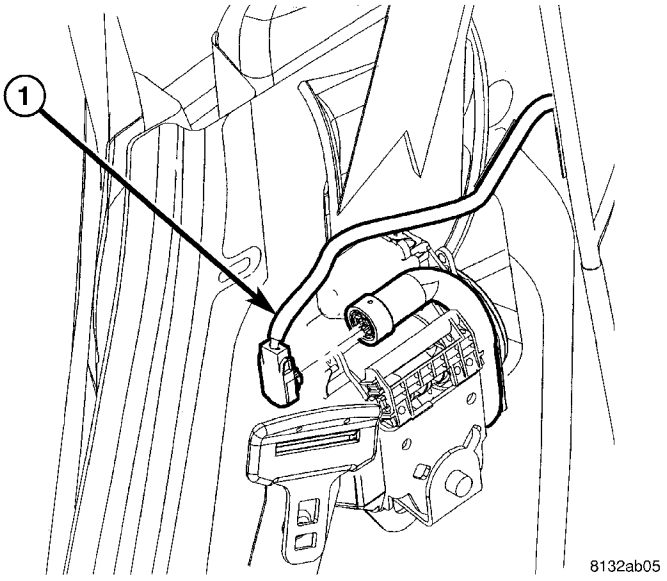

Fig. 22 TENSIONER SQUIB CONNECTOR

1 - TENSIONER SQUIB CONNECTOR

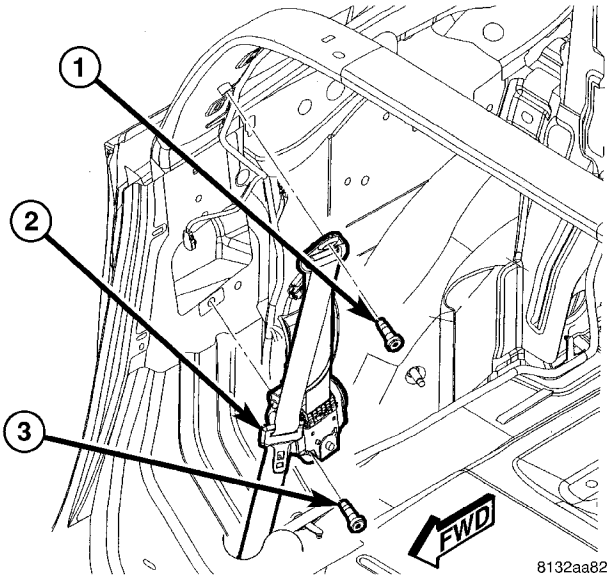

Fig. 23 RETRACTOR - REMOVE/INSTALL

1 - UPPER TURNING LOOP MOUNTING BOLT
2 - FRONT SEAT BELT RETRACTOR
3 - FRONT SEAT BELT RETRACTOR MOUNTING BOLT

WARNING: Do not connect the battery negative cable (Refer to 8 - ELECTRICAL/RESTRAINTS - DIAGNOSIS AND TESTING - AIRBAG SYSTEM). Personal injury or death may result if the system test is not performed first.

(8) Close hood.

(9) Verify vehicle and system operation.

FRONT SEAT BELT BUCKLE

REMOVAL

WARNING: FRONT SEAT BELT ASSEMBLIES MUST BE REPLACED AFTER A COLLISION.

(1) Remove center console (Refer to 23 - BODY/INTERIOR/CENTER CONSOLE - REMOVAL).
(2) Remove front seat cushion side shield two retaining screws.
(3) Remove bolt attaching seat belt buckle to seat.
(4) Remove seat belt buckle from seat.

INSTALLATION

WARNING: FRONT SEAT BELT ASSEMBLIES MUST BE REPLACED AFTER A COLLISION.

(1) Place seat belt buckle in position on seat anchor.
(2) Install bolt attaching seat belt buckle to seat. Tighten seat belt anchor bolt to 40 N·m (30 ft. lbs.) torque.
(3) Install front seat cushion side shield two screws.
(4) Install the center console (Refer to 23 - BODY/INTERIOR/CENTER CONSOLE - INSTALLATION).

FRONT SEAT BELT HEIGHT ADJUSTER

REMOVAL

WARNING: FRONT SEAT BELT ASSEMBLIES MUST BE REPLACED AFTER A COLLISION.

(1) Remove B-pillar trim (Refer to 23 - BODY/INTERIOR/B-PILLAR TRIM - REMOVAL).
(2) Remove the two bolts attaching front seat belt height adjuster to B-pillar (Fig. 24).
(3) Remove front seat belt height adjuster from vehicle.

INSTALLATION

WARNING: FRONT SEAT BELT ASSEMBLIES MUST BE REPLACED AFTER A COLLISION.

NOTE: Front seat belt height adjuster must be in the lowest position when Installing adjuster knob.

(1) Place into position the front seat belt height adjuster.

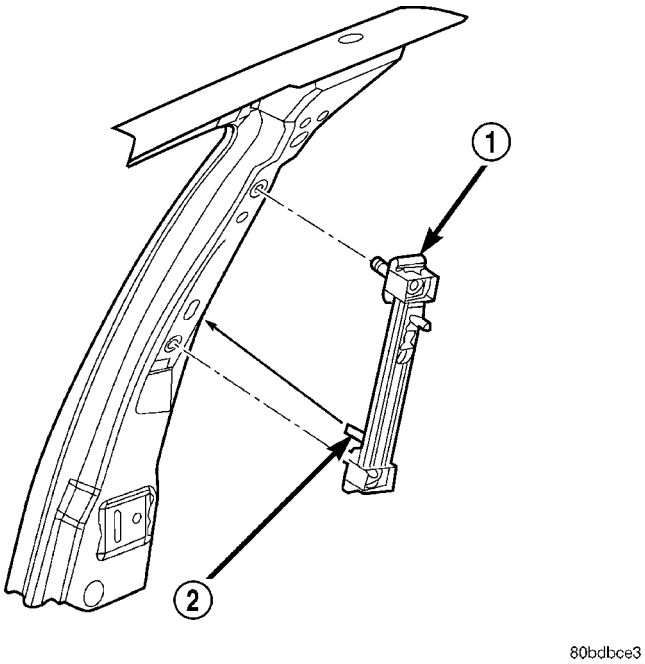

Fig. 24 FRONT SEAT BELT HEIGHT ADJUSTER

1 - FRONT SEAT BELT HEIGHT ADJUSTER
2 - TAB IS ON BOTTOM

(2) Install bolts attaching the front seat belt height adjuster to B-pillar. Tighten all seat belt bolts to 40 N·m (30 ft. lbs.) torque.
(3) Install B-pillar trim (Refer to 23 - BODY/INTERIOR/B-PILLAR TRIM - INSTALLATION).

OCCUPANT RESTRAINT CONTROLLER

DESCRIPTION

The Occupant Restraint Controller (ORC) is also sometimes referred to as the Airbag Control Module (ACM). The ORC is mounted on the tunnel floor pan, between the transmission shifter and parking brake (Fig. 25).

The ORC contains a microprocessor, the impact sensing device, and energy storage capacitors. The microprocessor contains the airbag system logic. The airbag system logic includes On-Board Diagnostics (OBD) capability, and communicates with the instrument cluster circuitry on the Programmable Communication Interface (PCI) data bus to control the airbag indicator lamp.

OPERATION

The impact sensing device is located inside the ORC. The sensing device provides crash severity discrimination and confirmation of a crash. The ORC monitors the system to determine the system readiness. The ORC contains on-board diagnostics (OBD),

OCCUPANT RESTRAINT CONTROLLER (Continued)

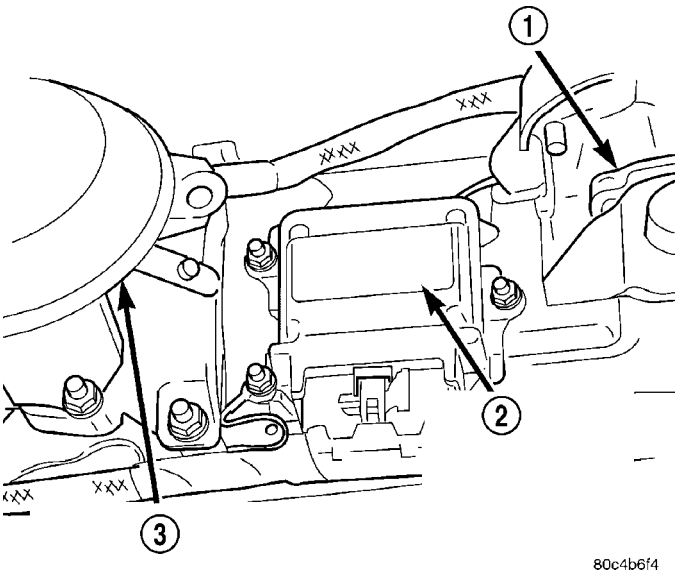

Fig. 25 OCCUPANT RESTRAINT CONTROLLER LOCATION

1 - PARKING BRAKE
2 - OCCUPANT RESTRAINT CONTROLLER
3 - CONSOLE GEAR SELECTOR

and will illuminate the AIRBAG warning lamp on the cluster when a fault occurs. The warning indicator is illuminated for six to eight seconds every time the vehicle is started.

The microprocessor in the ORC monitors internal components and the airbag system electrical circuits to determine the system readiness. If the ORC detects a monitored system fault, it sends messages to the instrument cluster over the PCI data bus to turn ON the airbag warning lamp. A decision algorithm in the ORC microprocessor determines when the deceleration rate is severe enough to require airbag system protection. When the appropriate conditions are met, the ORC sends an electrical signal to deploy the frontal airbags. The impact sensing device is an accelerometer that senses deceleration, which provides verification of the severity of an impact. The ORC is calibrated for the specific vehicle, and is only serviced as a unit. The ORC also contains an energy-storage capacitor. The purpose of the capacitor is to provide airbag system protection if the impact has damaged or disconnected the battery. The ORC cannot be repaired or adjusted, and if damaged or faulty, must be replaced.

REMOVAL

(1) Open hood.

(2) Disconnect and isolate the battery negative cable.

(3) Wait two minutes for the system reserve capacitor to discharge before servicing any airbag components.

(4) Remove the center console (Refer to 23 - BODY/INTERIOR/CENTER CONSOLE - REMOVAL).

(5) Remove ORC module mounting nuts and ground eyelet, then remove module (Fig. 26).

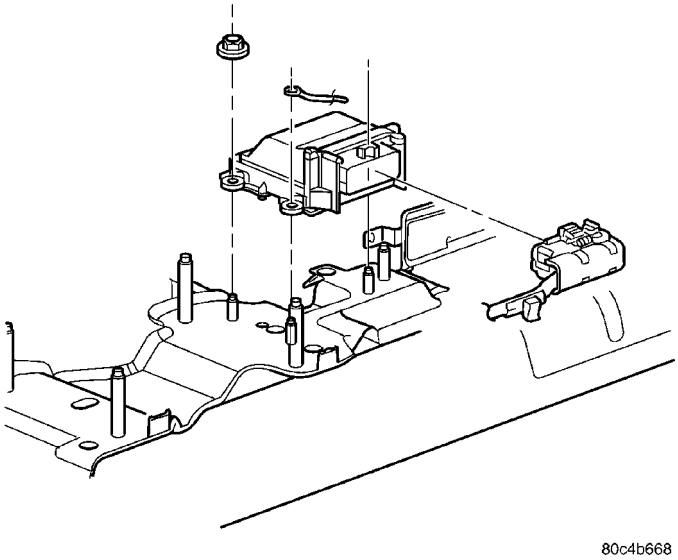

Fig. 26 OCCUPANT RESTRAINT CONTROLLER - REMOVE/INSTALL

(6) Disconnect ORC 23-way connector.

(7) Remove ORC from vehicle.

INSTALLATION

(1) Connect ORC connector and ensure that the connector and all locking tabs are engaged.

CAUTION: USE SUPPLIED NUTS ONLY

(2) Position ORC (arrow pointing forward) in the console floor bracket (Fig. 26), replace ground eyelet, and attach the nuts and tighten to 9.6 to 14 N·m (85 to 125 in. lbs.) torque.

NOTE: Place the ground eyelet over the front (towards the front of the vehicle) weld stud when reattaching the ORC.

(3) Install center console assembly (Refer to 23 - BODY/INTERIOR/CENTER CONSOLE - INSTALLATION).

WARNING: DO NOT CONNECT BATTERY NEGATIVE CABLE YET (Refer to 8 - ELECTRICAL/RESTRAINTS - DIAGNOSIS AND TESTING - AIRBAG SYSTEM).

(4) Close hood.

(5) Verify vehicle and system operation.

PASSENGER AIRBAG

DESCRIPTION

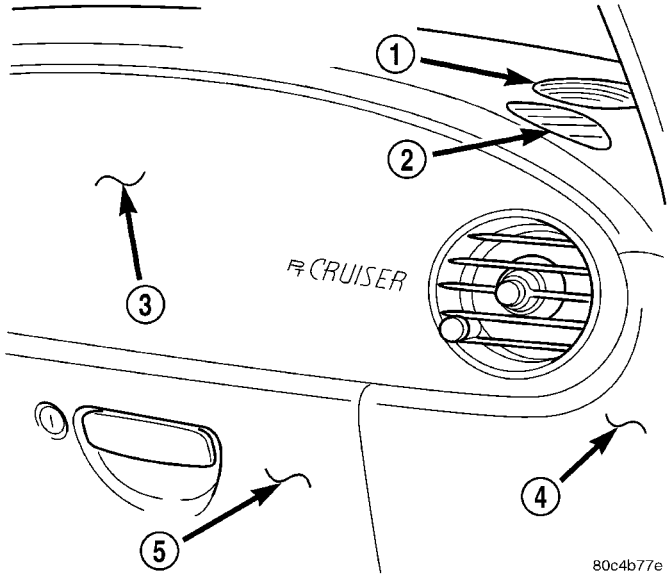

Fig. 27 PASSENGER AIRBAG LOCATION

1 - INSTRUMENT PANEL SPEAKER
2 - SIDE WINDOW DEMISTER
3 - PASSENGER AIRBAG
4 - RIGHT INSTRUMENT PANEL END COVER
5 - GLOVE BOX ASSEMBLY

The passenger airbag is located behind the passenger airbag cover, between the glove box and instrument panel top cover (Fig. 27).

The passenger airbag includes a stamped steel housing within which the cushion and inflator are mounted and sealed. Two stamped metal brackets, one on each end of the housing, enclose the cushion and inflator. The mounting scheme consists of two weld studs and a bracket with two tabs off the bottom of the housing.

Following a passenger airbag deployment, the passenger airbag and the passenger airbag cover must be replaced. If inspection reveals that the passenger airbag mounting points on the instrument panel structural duct have been cracked or damaged, the instrument panel assembly must also be replaced. The passenger airbag cannot be repaired, and must be replaced if deployed or in any way damaged.

OPERATION

The hybrid-type inflator assembly includes a small canister of highly compressed argon gas. The inflator seals the hole in the airbag cushion so it can discharge the gas it produces directly into the cushion when supplied with the proper electrical signal. Following an airbag deployment, the airbag cushion quickly deflates by venting this gas through the porous fabric material used on each end panel of the airbag cushion.

The passenger airbag is secured with screws to the instrument panel structural duct beneath the instrument panel top pad and above the glove box opening.

REMOVAL

NON-DEPLOYED AIRBAG

(1) Open hood.

(2) Disconnect and isolate the battery negative cable.

(3) Wait two minutes for the system reserve capacitor to discharge before servicing any airbag components.

(4) Remove instrument panel top cover (Refer to 23 - BODY/INSTRUMENT PANEL/INSTRUMENT PANEL TOP COVER - REMOVAL).

(5) Open glove box, push in on the box/bin sides and lower to floor.

(6) Remove the right instrument panel end cap.

(7) Remove four passenger airbag cover screws along the bottom end of the airbag cover.

(8) Remove two passenger airbag cover screws along the top edge of the airbag cover.

(9) Remove two nuts retaining passenger airbag to instrument panel assembly inside glove box opening (Fig. 28).

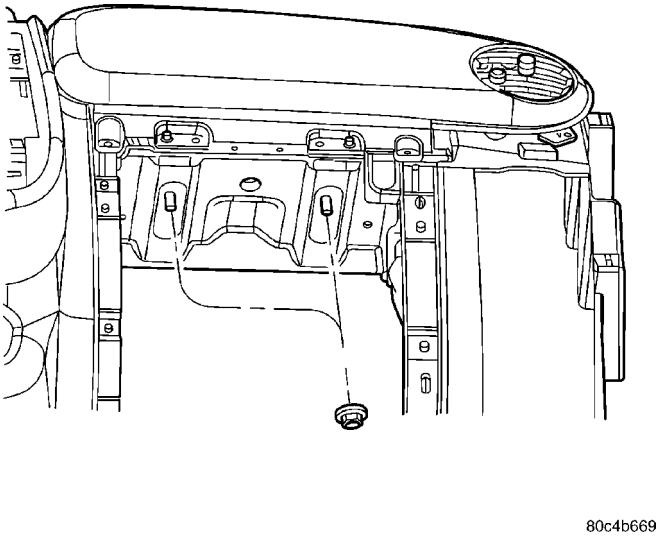

Fig. 28 PASSENGER AIRBAG RETAINING NUTS

(10) Lift airbag up until the wire connector is visible and disconnect the wire connector from airbag. Unlock the locking tab (Fig. 29) and release the connector (Fig. 30).

(11) Remove passenger airbag from vehicle.

PASSENGER AIRBAG (Continued)

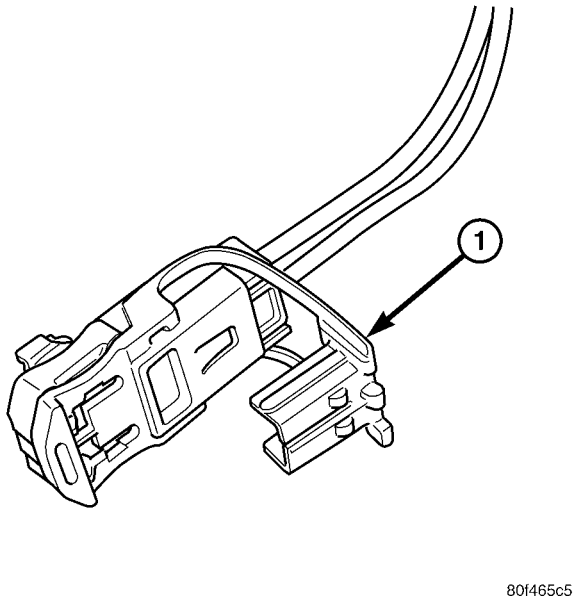

Fig. 29 ELECTRICAL CONNECTOR LOCK

1 - LOCKING TAB

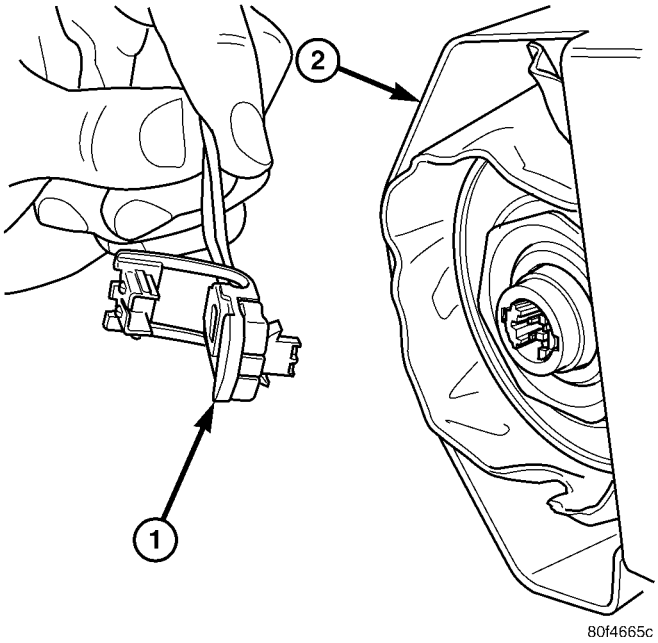

Fig. 30 PASSENGER AIRBAG ELECTRICAL CONNECTOR

1 - ELECTRICAL CONNECTOR
2 - PASSENGER AIRBAG

DEPLOYED AIRBAG

(1) Open hood.

(2) Disconnect and isolate the battery negative cable.

(3) Roll/fold airbag towards instrument panel.

(4) Close door over folded airbag and tape door closed.

(5) Remove instrument panel top cover (Refer to 23 - BODY/INSTRUMENT PANEL/INSTRUMENT PANEL TOP COVER - REMOVAL).

(6) Open glove box, push in on the box/bin sides and lower to floor.

(7) Remove the right instrument panel end cap.

(8) Remove four passenger airbag cover screws along the bottom end of the airbag cover.

(9) Remove two passenger airbag cover screws along the top edge of the airbag cover.

(10) Remove two nuts retaining passenger airbag to instrument panel assembly inside glove box opening (Fig. 28).

(11) Lift airbag up until the wire connector is visible and disconnect the wire connector from airbag. Unlock the locking tab and release the connector (Fig. 30).

(12) Remove passenger airbag from vehicle.

INSTALLATION

(1) Place airbag into instrument panel opening, connect the 4-way wire connector, and lock the red locking tab (Fig. 30).

(2) Install the two nuts retaining passenger airbag to instrument panel assembly inside glove box opening (Fig. 28). Torque the two airbag retaining nuts to 22 to 34 N·m (200 to 300 in. lbs.) torque.

(3) Install two passenger airbag cover screws along the top edge of the airbag cover. Torque trim screws to 2 N·m (20 in. lbs.).

(4) Install four passenger airbag cover screws along the bottom end of the airbag cover. Torque trim screws to 2 N·m (20 in. lbs.).

(5) Install the right instrument panel end cap.

(6) Push in on the box/bin sides and close glove box door.

(7) Install instrument panel top cover (Refer to 23 - BODY/INSTRUMENT PANEL/INSTRUMENT PANEL TOP COVER - INSTALLATION).

WARNING: DO NOT CONNECT BATTERY NEGATIVE CABLE YET (Refer to 8 - ELECTRICAL/RESTRAINTS - DIAGNOSIS AND TESTING - AIRBAG SYSTEM).

(8) Close hood.

(9) Verify vehicle and system operation.

PASSENGER AIRBAG COVER

REMOVAL

(1) Open hood.
(2) Disconnect and isolate the battery negative cable.
(3) Wait two minutes for the system reserve capacitor to discharge before servicing any airbag components.
(4) Remove the passenger airbag from the vehicle (Refer to 8 - ELECTRICAL/RESTRAINTS/PASSENGER AIRBAG - REMOVAL).
(5) Unsnap cover from passenger airbag and remove by lifting the airbag cover up towards the hinge.
(6) Reach in under the cover and push down on the metal flap running the length of the top of the airbag housing.
(7) Maneuver airbag cover out of the airbag housing.

INSTALLATION

If reinstalling the airbag cover onto the same passenger airbag, perform the following adjustment. Otherwise, go to Step 1.

- Using a 90° needle nose pliers or equivalent, place the pliers on the rear edge of the airbag cover metal flap retainer.
- Bend roughly 10° so that the metal flap is closed slightly to eliminate rattles of the airbag cover.
- Bend until the measurement of the metal flap to airbag housing is 7 - 8.3 mm (use a drill bit ranging from 9/32 - 21/64 inch).

(1) Snap cover onto the passenger airbag frame.
(2) Install the passenger airbag (Refer to 8 - ELECTRICAL/RESTRAINTS/PASSENGER AIRBAG - INSTALLATION).

WARNING: DO NOT CONNECT BATTERY NEGATIVE CABLE YET (Refer to 8 - ELECTRICAL/RESTRAINTS - DIAGNOSIS AND TESTING - AIRBAG SYSTEM).

(3) Close hood.
(4) Verify vehicle and system operation.

REAR CENTER SEAT BELT & RETRACTOR

REMOVAL

(1) Detach Quick Connect Anchor by depressing tab.
(2) Remove seat bezel.
(3) De-trim seat back upper (Refer to 23 - BODY/SEATS/SEAT BACK COVER - REMOVAL).
(4) Lock seat back latch.
(5) Disconnect Locking Cable from retractor.
(6) Remove retractor bolt.
(7) Feed webbing and hardware through seat frame and remove retractor.

INSTALLATION

(1) Feed webbing and hardware through seat frame and install retractor.
(2) Install retractor bolt and tighten to 40 N·m (30 ft. lbs.).
(3) Connect locking cable to retractor.
(4) Unlock seat back latch.
(5) Re-trim rear seat back cover (Refer to 23 - BODY/SEATS/SEAT BACK COVER - INSTALLATION).
(6) Install seat bezel.
(7) Attach Quick Connect Anchor.

REAR SEAT BELT & RETRACTOR

REMOVAL

(1) Remove turning loop cover.
(2) Remove turning loop bolt.
(3) Remove upper and lower trim bezels.
(4) Remove trim panel from body (Refer to 23 - BODY/INTERIOR/LEFT QUARTER TRIM PANEL - REMOVAL).
(5) Remove lower seat belt anchor bolt.
(6) Feed seat belt and hardware through trim openings.
(7) Unbolt and remove the retractor and belt assembly.

INSTALLATION

(1) Place rear seat belt retractor into position.
(2) Install bolt attaching retractor. Tighten the retractor belt bolt to 40 N·m (30 ft. lbs.) torque.
(3) Feed seat belt and hardware through trim opening.
(4) Install lower seat belt anchor bolt. Tighten to 40 N·m (30 ft. lbs.).
(5) Install trim panel (Refer to 23 - BODY/INTERIOR/LEFT QUARTER TRIM PANEL - INSTALLATION).
(6) Install upper and lower trim bezels.
(7) Install turning loop bolts.
(8) Install turning loop cover.

REAR SEAT BELT & RETRACTOR - PT27

REMOVAL

(1) Release hood latch and open hood.

(2) Disconnect and isolate the battery negative cable.

WARNING: Wait two minutes for the airbag system reserve capacitor to discharge before beginning any airbag system or component service. Failure to do so may result in accidental airbag deployment, personal injury or death.

(3) Remove the lower seat belt anchor nut (Fig. 31).

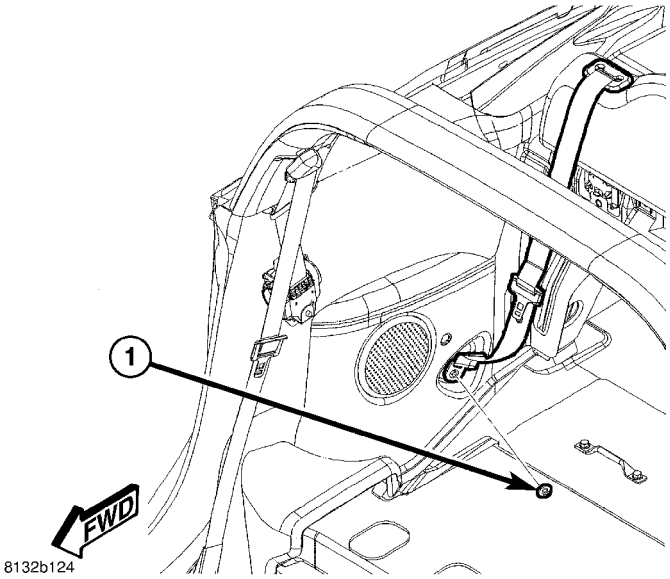

Fig. 31 SEAT BELT ANCHOR NUT - REMOVE/ INSTALL

1 - SEAT BELT ANCHOR NUT

(4) Remove the Lower Quarter Trim Panel the side in which you are removing the seat belt and retractor.

(5) Remove the four bolts to the rear seat upper bolster.

(6) Feed the seat belt webbing through the top of the bolster.

(7) Remove the one retaining bolt to the seat belt retractor (Fig. 32).

(8) Remove seat belt & retractor from vehicle.

INSTALLATION

(1) Position seat belt & retractor into vehicle.

(2) Install the one retaining bolt to the seat belt retractor (Fig. 32). Torque bolt to 40 N·m (30 ft. lbs.).

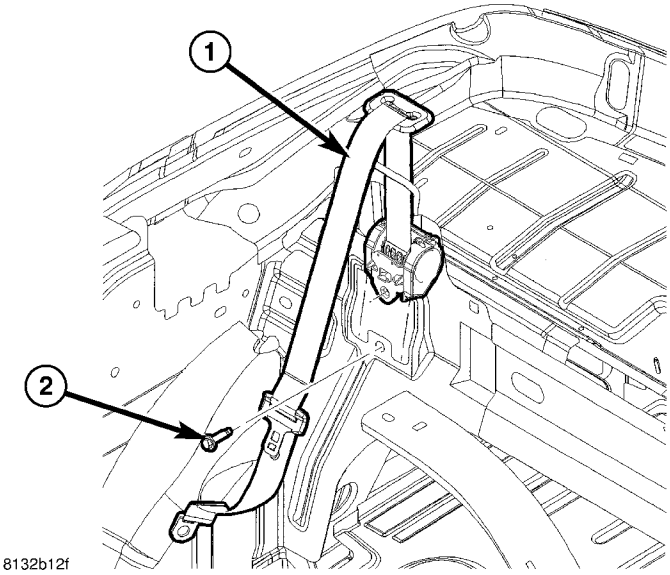

Fig. 32 SEAT BELT & RETRACTOR - REMOVE/ INSTALL

1 - SEAT BELT & RETRACTOR
2 - SEAT BELT RETRACTOR RETAINING BOLT

(3) Feed the seat belt webbing through the top of the rear seat upper bolster.

(4) Install the four bolts to the rear seat upper bolster.

(5) Install the Lower Quarter Trim Panel.

(6) Install the lower seat belt anchor nut (Fig. 31). Torque bolt to 40 N·m (30 ft. lbs.).

(7) Connect the battery negative cable.

(8) Close hood.

(9) Verify vehicle and system operation.

REAR SEAT BELT BUCKLE

REMOVAL

The rear seat belt buckles are riveted to the rear seat lower pivot. To service the rear seat belt buckles, the entire pivot assembly needs to be replaced.

REAR SEAT BELT BUCKLE - PT27

REMOVAL

(1) Open door and decklid.

(2) Release the fold down rear seat and pull forward.

(3) Remove the two screws at the side of the seat cushion shield at the buckle area (Fig. 33).

(4) Remove the two screws at the bottom of the cushion cover (Fig. 33).

REAR SEAT BELT BUCKLE - PT27 (Continued)

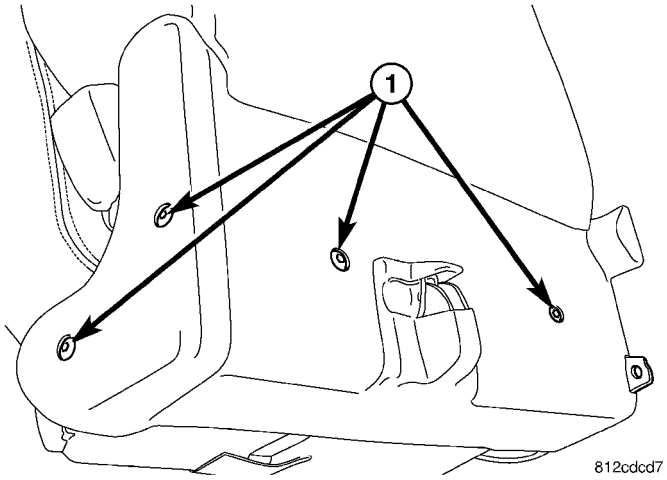

Fig. 33 REAR SEAT CUSHION COVER/SHIELD

1 - REAR SEAT CUSHION COVER RETAINING SCREWS (5)

(5) Pull cushion cover back far enough to get at the seat belt buckle anchor bolt.

(6) Remove the anchor bolt to the seat belt buckle (Fig. 34) and remove from seat.

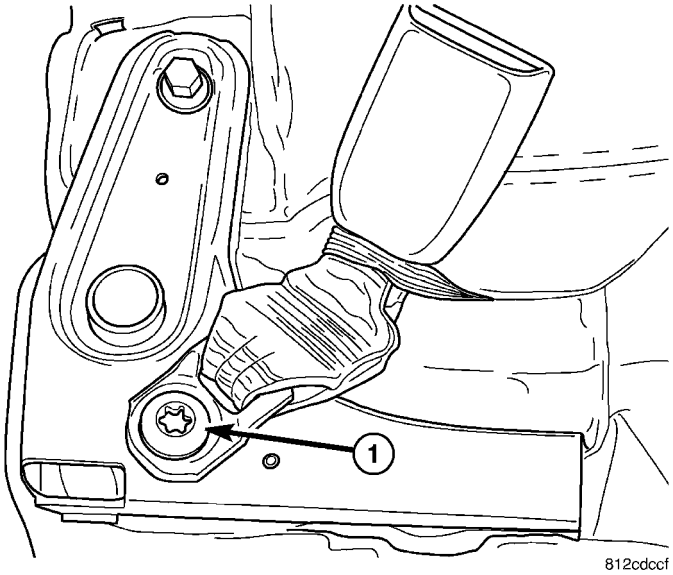

Fig. 34 SEAT BELT BUCKLE ANCHOR BOLT

1 - SEAT BELT BUCKLE ANCHOR BOLT (1)

INSTALLATION

(1) Pull cushion cover back far enough to get at the seat belt buckle anchor bolt.

(2) Position the seat belt buckle into position and install the anchor bolt (Fig. 34).

(3) Install the two screws at the bottom of the cushion cover (Fig. 33).

(4) Install the two screws at the side of the seat cushion shield at the buckle area (Fig. 33).

(5) Return the rear seat to the unfolded position.

(6) Verify seat belt operation is free and not binding.

(7) Close door and decklid.

SATELLITE ACCELERATION SENSOR

DESCRIPTION

Vehicles equipped with side impact airbags use two impact or Satellite Acceleration Sensors (SAS). One is located on each respective side body B-pillar.

The satellite acceleration sensors are electronic accelerometers that sense the rate of vehicle deceleration and when combined with the Occupant Restraint Controller (ORC) accelerometer provides verification of the direction and severity of a side impact. Each sensor also contains an electronic communication chip that allows the unit to communicate the sensor status as well as sensor fault information to the microprocessor in the ORC.

Refer to the appropriate wiring information and Body Diagnostic Procedures manual for diagnosis and testing.

OPERATION

The Satellite Acceleration Sensor (SAS) provides verification of the direction and severity of the side impact to the Occupant Restraint Controller (ORC). The ORC controls both the right and the left right side seat airbags. In the event of a side impact the ORC will send an electronic signal to deploy the appropriate seat airbag. The SAS periodically transmit the acceleration data to the ORC by modulation of the current on the power supply.

The accelerometer pulses are sent to a microprocessor, which contains a decision algorithm. When an impact is severe enough to require airbag protection, the ORC microprocessor sends a signal to deploy the side airbag that completes the electrical circuits to the right or left side airbag. The ORC is calibrated for the specific vehicle and reacts to the severity and direction of the impact.

The ORC microprocessor continuously monitors all of the passive restraint system electrical circuits to determine the system readiness. If the ORC detects a system fault, it sets a Diagnostic Trouble Code (DTC) and controls the airbag warning indicator operation accordingly. The side impact sensors receive battery current and ground through dedicated driver and passenger sensor signal and ground circuits from the ORC. If the sensor is dropped it must be replaced. Disconnect the battery or remove both airbag fuses before servicing impact sensors.

SATELLITE ACCELERATION SENSOR (Continued)

REMOVAL

(1) Disconnect and isolate the battery negative cable remote terminal.

(2) Wait two minutes for the system reserve capacitor to discharge before servicing any airbag components.

(3) Remove the lower B-pillar trim from the appropriate side of the vehicle. Refer to Body, Interior, B-Pillar Lower Trim, Removal.

(4) Disconnect the satellite acceleration sensor (SAS) electrical connector.

(5) Remove the SAS retaining screws and remove the sensor from the vehicle.

INSTALLATION

(1) Position the satellite acceleration sensor (SAS) in B-pillar (electrical connector facing forward in vehicle) and install the retaining screws. Torque the screws to 7 N·m (62 in. lbs.).

(2) Connect the SAS electrical connector.

(3) Install the lower B-pillar trim. Refer to Body, Interior, B-Pillar Lower Trim, Installation.

WARNING: DO NOT CONNECT THE BATTERY NEGATIVE CABLE REMOTE TERMINAL. REFER TO ELECTRICAL, RESTRAINTS, DIAGNOSIS AND TESTING - AIRBAG SYSTEM FIRST. FAILURE TO DO SO COULD RESULT IN OCCUPANT PERSONAL INJURY OR DEATH.

SATELLITE ACCELERATION SENSOR - PT27

DESCRIPTION

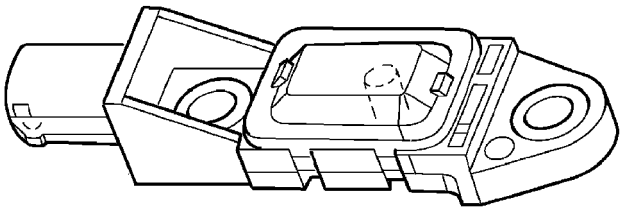

Fig. 35 SATELLITE ACCELERATION SENSOR

Vehicles equipped with side impact airbags use two impact or Satellite Acceleration Sensors (SAS) (Fig. 35). One is located on each respective side, just in front of the B-pillar (Fig. 36).

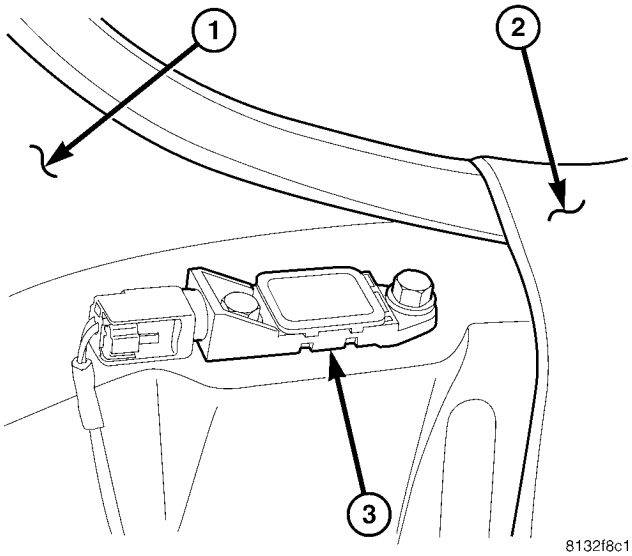

Fig. 36 SAS LOCATION

1 - B-PILLAR
2 - SILL PLATE
3 - SATELLITE ACCELERATION SENSOR

The SAS's are electronic accelerometers that sense the rate of vehicle deceleration and when combined with the Occupant Restraint Controller (ORC) accelerometer, provides verification of the direction and severity of a side impact. Each sensor also contains an electronic communication chip that allows the unit to communicate the sensor status as well as sensor fault information to the microprocessor in the ORC.

For diagnosis and testing, use a scan tool and refer to the appropriate body diagnostic information.

OPERATION

The Satellite Acceleration Sensor (SAS) provides verification of the direction and severity of the side impact to the Occupant Restraint Controller (ORC). The ORC controls both the right and the left right side seat airbags. In the event of a side impact the ORC will send an electronic signal to deploy the appropriate seat airbag. The SAS periodically transmit the acceleration data to the ORC by modulation of the current on the power supply.

The accelerometer pulses are sent to a microprocessor, which contains a decision algorithm. When an impact is severe enough to require airbag protection, the ORC microprocessor sends a signal to deploy the side airbag that completes the electrical circuits to the right or left side airbag. The ORC is calibrated for the specific vehicle and reacts to the severity and direction of the impact.

The ORC microprocessor continuously monitors all of the passive restraint system electrical circuits to determine the system readiness. If the ORC detects a

SATELLITE ACCELERATION SENSOR - PT27 (Continued)

system fault, it sets a Diagnostic Trouble Code (DTC) and controls the airbag warning indicator operation accordingly. The side impact sensors receive battery current and ground through dedicated driver and passenger sensor signal and ground circuits from the ORC. If the sensor is dropped it must be replaced.

REMOVAL

(1) Open hood.

(2) Disconnect and isolate the battery negative cable.

(3)

WARNING: Wait two minutes for the airbag system reserve capacitor to discharge before beginning any airbag system or component service. Failure to do so may result in accidental airbag deployment, personal injury or death.

(4) Remove the lower quarter trim from the appropriate side of the vehicle.

(5) Disconnect the Satellite Acceleration Sensor (SAS) electrical connector (Fig. 37).

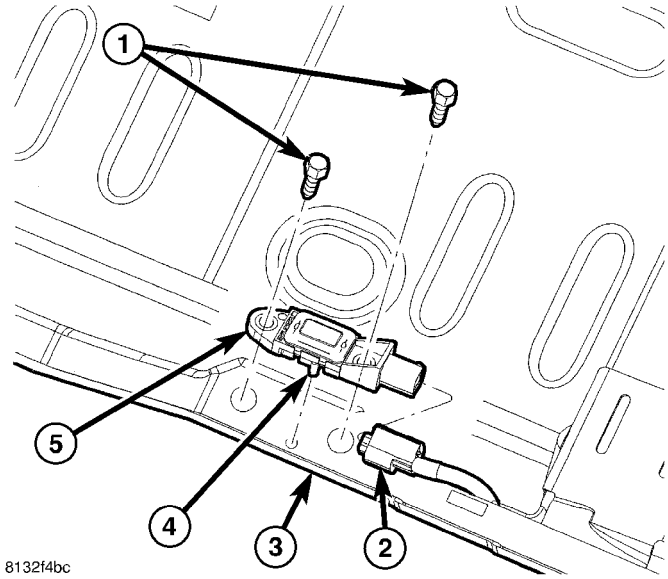

Fig. 37 SATELLITE ACCELERATION SENSOR - REMOVE/INSTALL

1 - SAS RETAINING SCREW
2 - SAS ELECTRICAL CONNECTOR
3 - BODY SIDE SILL PANEL
4 - SAS INDEXING PIN
5 - SATELLITE ACCELERATION SENSOR

(6) Remove the SAS retaining screws and remove the sensor from the vehicle (Fig. 37).

INSTALLATION

(1) Position the satellite acceleration sensor (SAS) in position (Fig. 36).

(2) Install the retaining screws (Fig. 37). Torque the screws to 8.5 N·m (75 in. lbs.).

(3) Connect the SAS electrical connector (Fig. 37).

(4) Install the quarter panel trim.

WARNING: Do not connect the battery negative cable (Refer to 8 - ELECTRICAL/RESTRAINTS - DIAGNOSIS AND TESTING - AIRBAG SYSTEM). Personal injury or death may result if the system test is not performed first.

(5) Verify vehicle and system operation.

(6) Close hood.

SEAT AIRBAG

DESCRIPTION

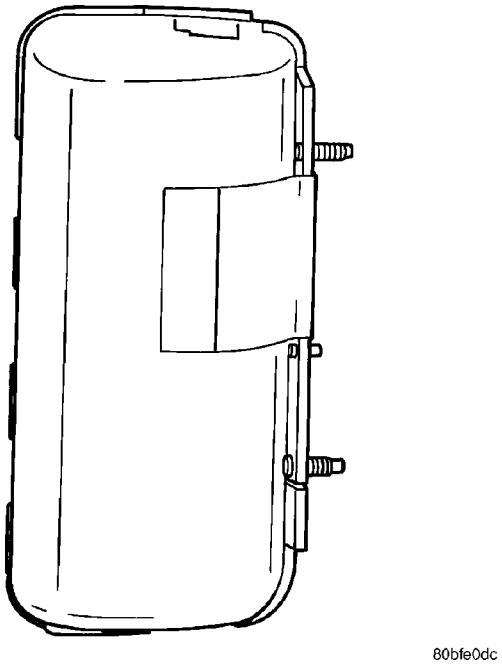

Fig. 38 SEAT AIRBAG - TYPICAL

The left and right seat airbags (Fig. 38) are located in the outboard end of the front seat backs. The airbag contains a bag, an inflator (small canister of highly compressed gas), and a mounting bracket. The seat airbag cannot be repaired and must be replaced, with the entire seat back assembly, if deployed or in any way damaged.

OPERATION

When supplied with the proper electrical signal, the inflator seals the hole in the airbag cushion so it can discharge the compressed gas it contains directly into the cushion. Upon deployment, the seat back trim cover will tear open and allow the seat airbag to fully deploy between the seat and the door.

SEAT AIRBAG (Continued)

REMOVAL

DEPLOYED SEAT AIRBAG

WARNING: DO NOT REPLACE A DEPLOYED SEAT AIRBAG. IF THE SEAT AIRBAG HAS BEEN DEPLOYED, THE ENTIRE SEAT BACK AND ALL DAMAGED PARTS MUST BE REPLACED.

If the seat airbag was deployed, the entire seat back must be replaced (Refer to 23 - BODY/SEATS/SEAT BACK - REMOVAL).

NONDEPLOYED SEAT AIRBAG

WARNING: ONLY REPLACE A NONDEPLOYED SEAT AIRBAG IF FAULTY OR DEFECTIVE.

(1) Position the front seat in the full forward position.
(2) Open hood.
(3) Disconnect and isolate the battery negative cable (Fig. 39).
(4) Wait two minutes for the system reserve capacitor to discharge before servicing any airbag components.

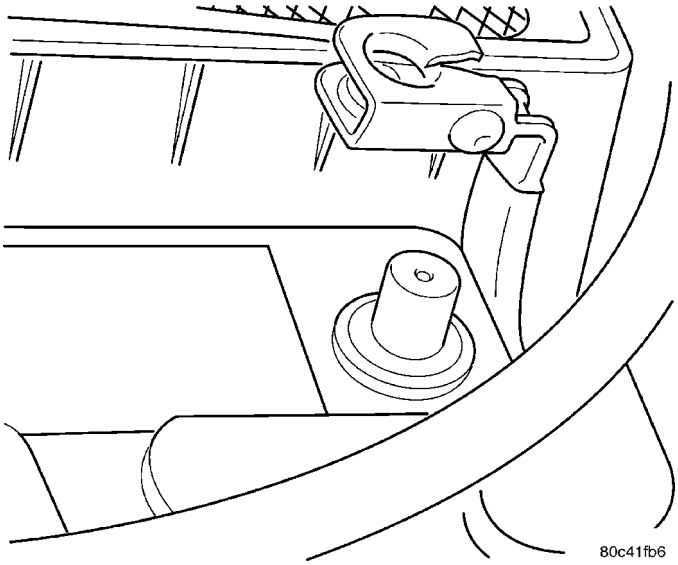

Fig. 39 BATTERY NEGATIVE CABLE - REMOVE/INSTALL

(5) Remove front seat from vehicle (Refer to 23 - BODY/SEATS/SEAT - REMOVAL).
(6) Remove plastic back panel from the seat back (Fig. 40).
(7) Disengage seat back trim cover J-strap from the upper, lower and airbag side of seat back.
(8) Disconnect the seat airbag electrical connector (Fig. 41). Slide the yellow locking tab down to unlock. Then with two fingers, push two side retaining tabs in and pull connector straight from module.

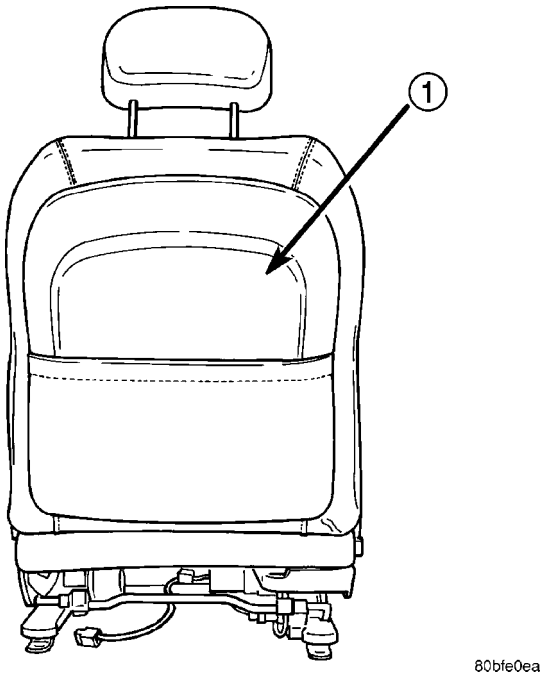

Fig. 40 FRONT SEAT BACK REAR PANEL

1 - FRONT SEAT BACK REAR PANEL

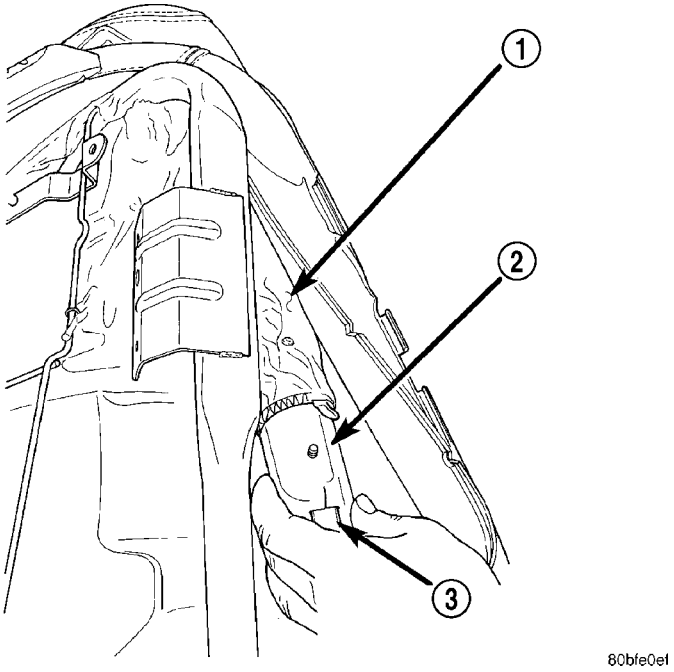

Fig. 41 SEAT AIRBAG ELECTRICAL CONNECTOR

1 - SEAT AIRBAG NYLON SLEEVE
2 - SEAT AIRBAG
3 - SEAT AIRBAG ELECTRICAL CONNECTOR

(9) Remove the seat airbag retaining nuts.
(10) Grasp the upper airbag side of the seat back trim cover and pull trim cover and cushion over top of seat back frame. This will allow room to remove seat airbag without damaging trim cover or cushion.

SEAT AIRBAG (Continued)

(11) Working between seat back trim cover/cushion and frame carefully unhook seat airbag studs from nylon sleeve and slide airbag out of sleeve. Be careful not to tear nylon sleeve as this will affect function of airbag system.

CAUTION: Be certain not to tear the seat airbag nylon sleeve during removal.

INSTALLATION

DEPLOYED SEAT AIRBAG

WARNING: DO NOT REPLACE A DEPLOYED SEAT AIRBAG. IF THE SEAT AIRBAG HAS BEEN DEPLOYED, THE ENTIRE SEAT BACK AND ALL DAMAGED PARTS MUST BE REPLACED.

If the seat airbag was deployed, the entire seat back must be replaced (Refer to 23 - BODY/SEATS/ SEAT BACK - INSTALLATION).

NONDEPLOYED SEAT AIRBAG

WARNING: ONLY REPLACE A NONDEPLOYED SEAT AIRBAG IF FAULTY OR DEFECTIVE.

NOTE: The seat airbag connector must face down (toward seat cushion) after installation.

(1) Carefully slide the side airbag in nylon sleeve until mounting studs line up with holes provided in nylon sleeve. Be careful not to tear nylon sleeve as this will affect function of airbag system.

CAUTION: The side airbag must be inside the nylon sleeve before installing retaining nuts. Failure to do so will adversely affect the function of the side impact airbag system.

(2) Pull seat airbag and nylon sleeve assembly up to line up mounting studs with holes provided in seat back frame mounting bracket (Fig. 42). Install the seat airbag retaining nuts. Torque to 10.7 N·m (94.7 in. lbs.).

(3) Position the upper seat back trim cover and cushion over seat back frame.

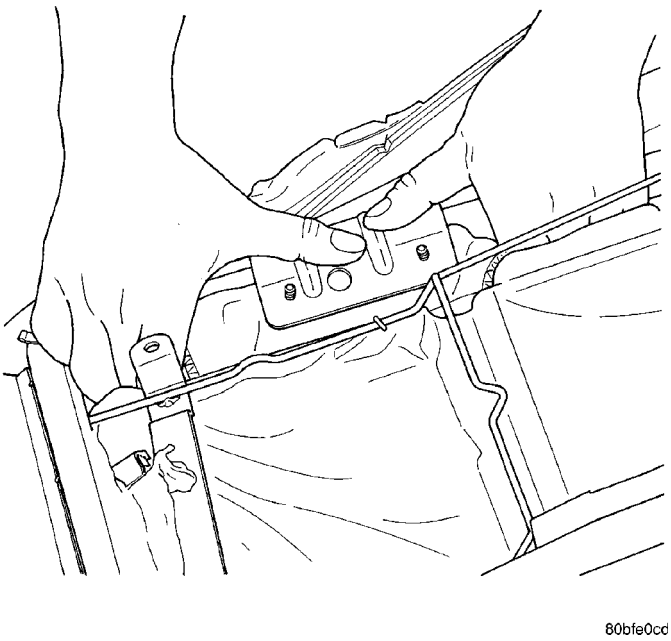

Fig. 42 INSTALLING SIDE AIRBAG INTO SEAT BACK

(4) Connect the seat airbag electrical connector. After initial connector is installed be certain the yellow locking tab is in the upper “locked” position. Check to be certain connector cannot be removed once yellow locking tab is positioned.

(5) Position seat back trim cover and install seat back trim cover J-straps on the upper, lower and airbag side of seat back frame.

(6) Install the plastic back panel on the seat back (Fig. 40). Install four screws in the upper mounting location of the back cover.

CAUTION: Be certain plastic back panel is securely installed on the seat back. Failure to do so will adversely affect the side impact airbag system.

(7) Install the front seat in vehicle (Refer to 23 - BODY/SEATS/SEAT - INSTALLATION).

WARNING: DO NOT CONNECT BATTERY NEGATIVE CABLE YET (Refer to 8 - ELECTRICAL/RESTRAINTS - DIAGNOSIS AND TESTING - AIRBAG SYSTEM).

(8) Close hood.

(9) Verify vehicle and system operation.

SEAT BELT CINCH BAR

STANDARD PROCEDURE - SEAT BELT CINCH BAR VERIFICATION TEST

WARNING: THE SEAT BELT CINCH BAR, CINCH BAR COVER OR ANY OTHER SEAT BELT COMPONENT MUST NEVER BE PAINTED. PAINT MAY CHANGE THE WAY IN WHICH THE SEAT BELT COMPONENTS PERFORM. FAILURE TO SO COULD RESULT IN OCCUPANT PERSONAL INJURY OR DEATH.

The latch plates of seat belts installed in certain positions may be equipped with an automatic cinching feature (Fig. 43). The cinch bar mechanism is designed to maintain the adjustment of the lap portion of the belt webbing when the belt is buckled, but allow the belt webbing to slide freely through the latch plate for proper adjustment or storage when the belt is not buckled. The following procedure will verify proper seat belt cinch bar operation.

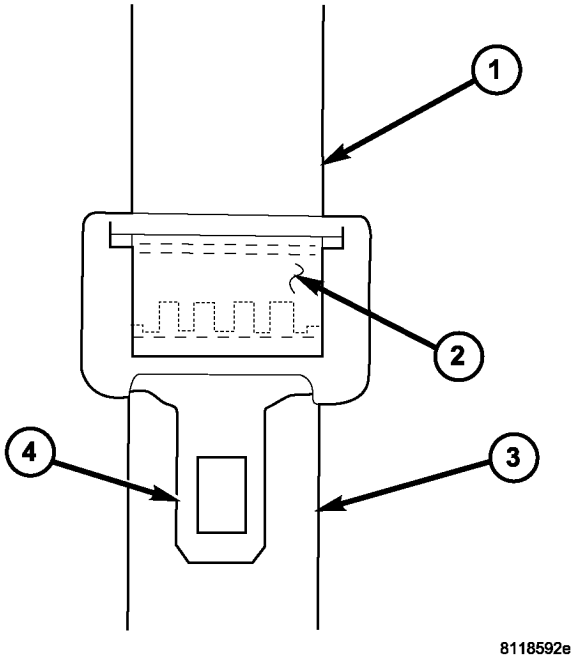

Fig. 43 SEAT BELT CINCH BAR

1 - SHOULDER BELT SIDE
2 - CINCH BAR MECHANISM
3 - LAP BELT SIDE
4 - LATCH PLATE

(1) Pull the suspect seat belt latch plate and webbing across the seat and insert the latch plate into the buckle until it is fully engaged (Fig. 44).

(2) Place a paper clip or a small piece of tape on the belt webbing on the lap belt side (not the shoulder belt side) of the latch plate as a reference mark of the latch plate location.

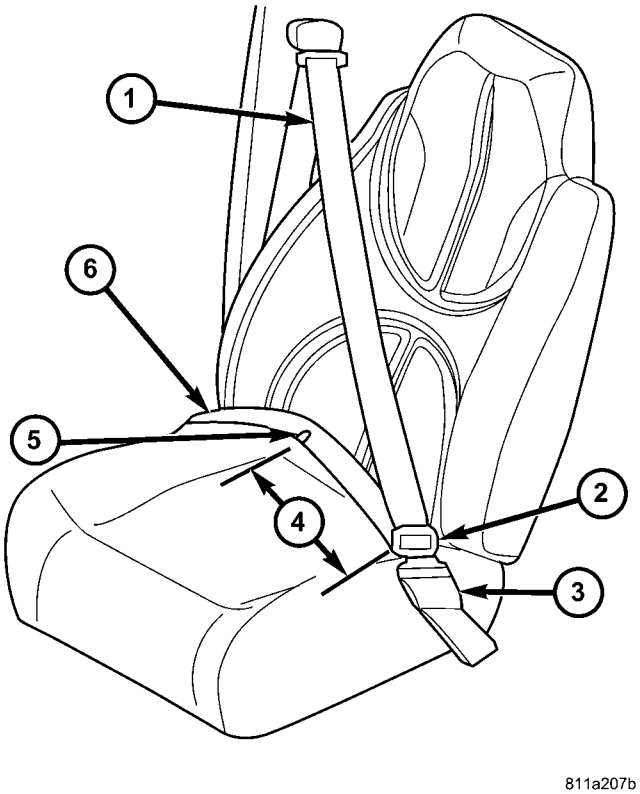

Fig. 44 SEAT BELT CINCH BAR VERIFICATION TEST

1 - SHOULDER BELT
2 - LATCH PLATE
3 - BUCKLE
4 - 38 CENTIMETERS (15 INCHES)
5 - REFERENCE MARK (TAPE OR PAPER CLIP)
6 - LAP BELT

(3) Release the seat belt latch plate from the buckle and pull another 38 centimeters (15 inches) of the belt webbing as measured from the latch plate reference mark location through to the lap belt side of the latch plate.

(4) Reinsert the latch plate into the buckle until it is fully engaged.

(5) Firmly grasp the center of the lap belt webbing, then pull the belt webbing upwards and towards the front of the vehicle while noting whether any of the webbing pulls through the latch plate.

(6) The cinch bar should engage the belt webbing and prevent it from being pulled through to the lap belt side of the latch plate. If the cinching mechanism is loose or fails to maintain proper lap belt adjustment while the latch plate is buckled, a seat belt cinch bar repair is required. (Refer to 8 - ELECTRICAL/RESTRAINTS/SEAT BELT CINCH BAR - REMOVAL).

SEAT BELT CINCH BAR (Continued)

REMOVAL

Before removing the cinch bar, verify that the cinch bar holds the belt from sliding through the latch plate. (Refer to 8 - ELECTRICAL/RESTRAINTS/SEAT BELT CINCH BAR - STANDARD PROCEDURE - SEAT BELT CINCH BAR VERIFICATION TEST). If the cinch bar components are not present in the seat belt latch plate, go directly to the installation procedure. (Refer to 8 - ELECTRICAL/RESTRAINTS/SEAT BELT CINCH BAR - INSTALLATION).

(1) Using a small screwdriver or equivalent, release the two cinch bar cover catches (Fig. 45).

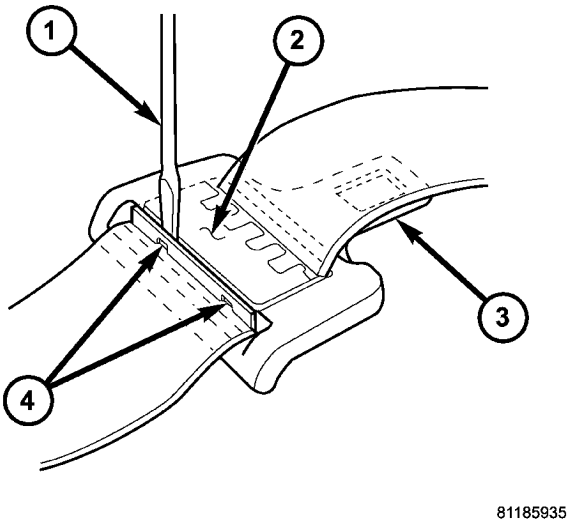

Fig. 45 CINCH BAR COVER REMOVE

1 - SCREWDRIVER
2 - CINCH BAR COVER
3 - LATCH PLATE
4 - CATCH (2)

(2) Remove and discard the cinch bar cover, the cinch bar and the two small springs (Fig. 46).

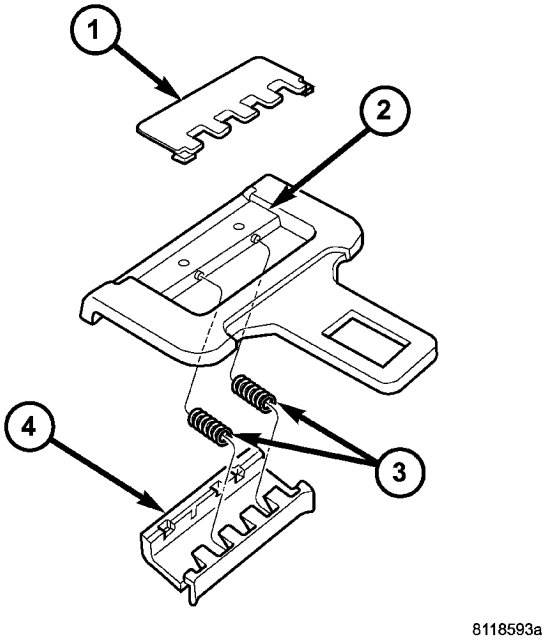

Fig. 46 CINCH BAR REMOVE

1 - CINCH BAR COVER
2 - LATCH PLATE BAR
3 - SPRING (2)
4 - CINCH BAR

INSTALLATION

WARNING: THE SEAT BELT CINCH BAR, CINCH BAR COVER OR ANY OTHER SEAT BELT COMPONENT MUST NEVER BE PAINTED. PAINT MAY CHANGE THE WAY IN WHICH THE SEAT BELT COMPONENTS PERFORM. FAILURE TO SO COULD RESULT IN OCCUPANT PERSONAL INJURY OR DEATH.

(1) Snap the new cinch bar onto the latch plate bar by pushing up on the bottom edge of the cinch bar. Be certain the new cinch bar is fully engaged around the latch plate bar (Fig. 47).

(2) Install two of the three springs provided in the repair package by positioning them over the dimples on the latch plate bar, then into the second slot from each end of the cinch bar (Fig. 48). The springs might not be exactly perpendicular to the cinch bar. This is acceptable.

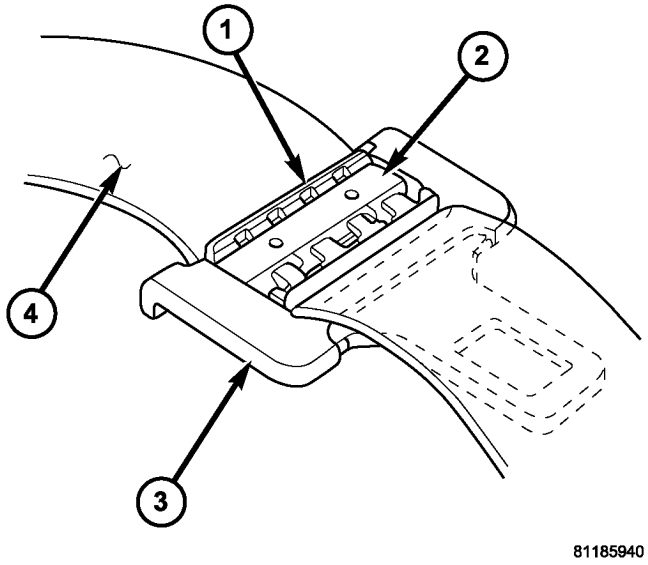

Fig. 47 CINCH BAR INSTALL

1 - CINCH BAR
2 - LATCH PLATE BAR

3 - LATCH PLATE BAR

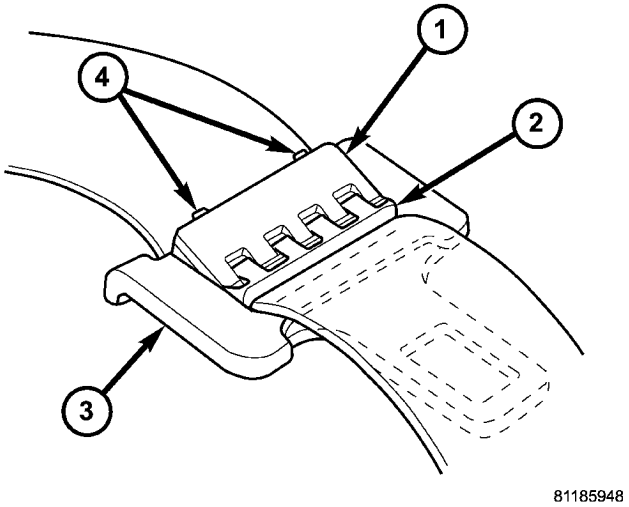

Fig. 49 CINCH BAR COVER INSTALL

1 - CINCH BAR COVER
2 - CINCH BAR
3 - LATCH PLATE
4 - CATCH (2)

(3) Align the cinch bar cover with the slots in the cinch bar, then slide the cover forward and snap it into place (Fig. 49). Be certain both cover catches are fully engaged.

(4) Connect the seat belt latch plate to the buckle and pull the webbing tight. Verify that the cinch bar holds the belt from sliding through the latch plate. (Refer to 8 - ELECTRICAL/RESTRAINTS/SEAT BELT CINCH BAR - STANDARD PROCEDURE - SEAT BELT CINCH BAR VERIFICATION TEST).

SPEED CONTROL

DESCRIPTION

The speed control system is electronically controlled and vacuum operated. The electronic control is integrated into the Powertrain Control Module, located on the left side of the engine compartment next to the air cleaner. The controls are located on the steering wheel and consist of a single switch. The ON, OFF, RESUME, ACCEL, SET, COAST, and CANCEL, lever is located on the right of the steering wheel (Fig. 1). For identification and location of the major components (Fig. 2).

The system is designed to operate at speeds above 25 mph (40 km/h).

WARNING: THE USE OF SPEED CONTROL IS NOT RECOMMENDED WHEN DRIVING CONDITIONS DO NOT PERMIT MAINTAINING A CONSTANT SPEED, SUCH AS IN HEAVY TRAFFIC OR ON ROADS THAT ARE WINDING, ICY, SNOW COVERED, OR SLIPPERY.

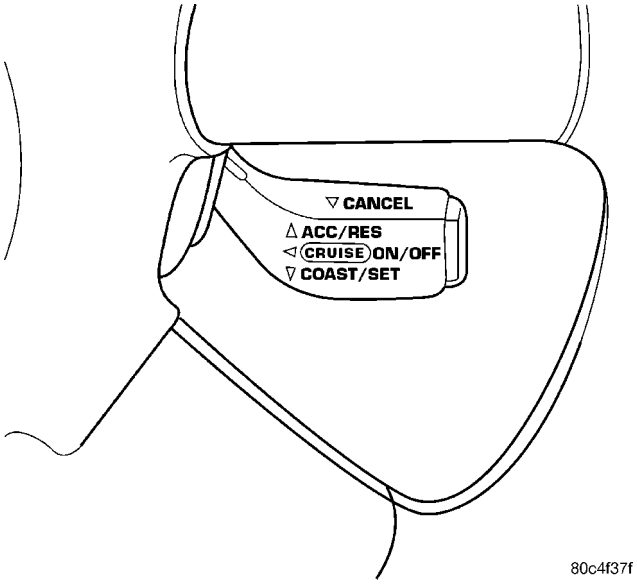

Fig. 1 Speed Control Switch

SPEED CONTROL (Continued)

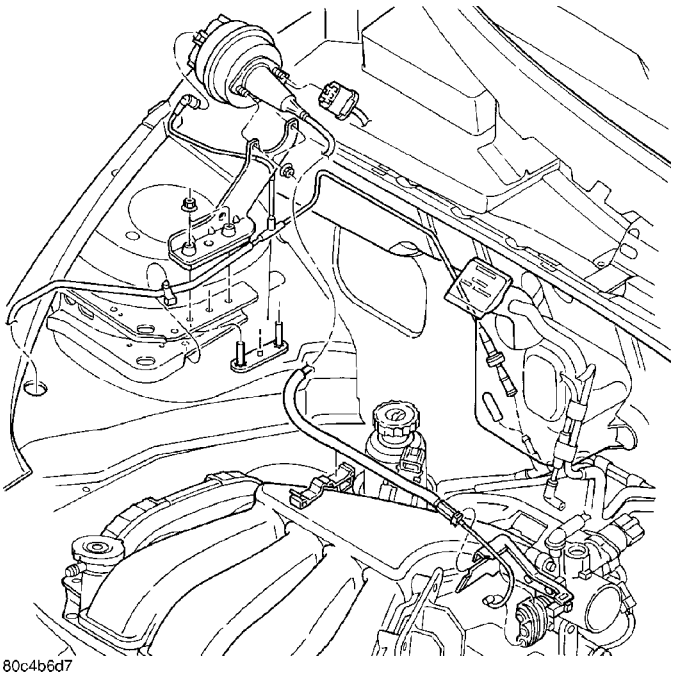

Fig. 2 Speed Control System

OPERATION

OPERATION

When speed control is activated by depressing the ON switch, the PCM allows a set speed to be stored in RAM for speed control. To store a set speed, depress and release the SET switch while the vehicle is moving at a speed between 25 and 85 mph. In order for the speed control to engage, the brakes cannot be applied, nor can the gear selector be indicating the transmission is in Park or Neutral (ATX) or 1st/2nd gear (MTX). The speed control can be disengaged manually by:

- Stepping on the brake pedal
- Depressing the OFF switch
- Depressing the CANCEL switch.
- Depressing the clutch pedal
- Operating in 1st or 2nd gear (autostick, if equipped)

NOTE: Turning the system off by depressing the OFF switch or turning off the ignition switch will erase the set speed stored in the PCM.

For added safety, the speed control system is programmed to disengage for any of the following conditions:

- An indication of Park or Neutral
- A rapid increase rpm (indicates that the clutch has been disengaged)
- Excessive engine rpm (indicates that the transmission may be in a low gear)
- The speed signal increases at a rate of 10 mph per second (indicates that the co-efficient of friction between the road surface and tires is extremely low)
- The speed signal decreases at a rate of 10 mph per second (indicates that the vehicle may have decelerated at an extremely high rate)
- If the actual speed is greater than 20 mph over the set speed.
- Autostick shifts into 1st or 2nd gear (autostick, if equipped)

Once the speed control has been disengaged, depressing the RESUME switch when speed is greater than 20 mph allows the vehicle to resume control to the target speed that was stored in the PCM.

While the speed control is engaged, the driver can increase the vehicle speed by depressing the ACCEL switch. The new target speed is stored in the PCM when the ACCEL switch is released. The PCM also has a ″tap-up″ feature in which target speed increases by 2 mph for each momentary switch activation of the ACCEL switch. The PCM also provides a means to decelerate to a new lower target speed without disengaging speed control. Depress and hold the COAST switch until the desired speed is reached, then release the switch.

The PCM also has a “Tap Down” feature in which target speed decreases at 1 mph for each momentary switch activation of the coast switch.

OPERATION - INTERACTIVE SPEED CONTROL (4 Speed EATX Only)

Interactive means that communication between the PCM and the TCM is taking place, this communication is internal to the PCM on NGC vehicles. Interactive speed control avoids unnecessary shifting for smoother, quieter operation and when downshifts are required, makes the shifts smoother.

CLIMBING A GRADE

DESCRIPTION

When climbing a grade the interactive speed control tries to maintain the set speed by increasing the throttle opening, while inhibiting/delaying downshifts.

OPERATION

If opening the throttle alone cannot maintain the set speed and the vehicle speed drops more than three mph below the set speed, the transmission will downshift to third gear. If the vehicle continues to lose speed, by more than 6 mph, the transmission will downshift again to maintain the set speed. After the vehicle encounters a less-steep grade, or has crested the grade (reduced the load on the power-

SPEED CONTROL (Continued)

train) and can maintain the set speed at a reduced throttle position, the transmission will upshift, as appropriate, until the set speed can be maintained in Overdrive.

GRADE HUNTING

DESCRIPTION

All vehicles equipped with a four speed automatic transmission have a grade hunting feature for the 2nd to 3rd gear upshift and the 3rd to Overdrive upshift.

OPERATION

The PCM on NGC vehicles identifies the powertrain loading conditions and selects the proper gear to maintain the current vehicle speed. Under moderate loading conditions the transaxle will stay in 3rd gear until the top of the grade is reached or the powertrain loading is reduced.

If powertrain loading is severe, the transaxle may shift into 2nd gear and remain there until powertrain loading is reduced, then a 2nd to 3rd gear upshift will be scheduled. Grade hunting features always operate regardless of whether or not the interactive speed control is engaged. **If the interactive speed control is not engaged and powertrain loading is not reduced, the driver may have to completely lift off of the throttle before an upshift will occur**. If the driver does lift off the throttle to induce an upshift under these conditions, vehicle speed will reduce and the Overdrive to 3rd and 3rd to 2nd gear downshifts will reoccur when the throttle is reapplied. If grade hunting is repeatedly induced by the driver, transaxle damage may result.

AUTOMATIC SPEED CONTROL OVERSPEED REDUCTION

DESCRIPTION

Transmission control software includes an automatic speed control overspeed reduction feature. This maintains vehicle speed at the selected set point when descending a grade.

OPERATION

The PCM on NGC vehicles first senses that the speed control is set. If the set speed is exceeded by more than 4 mph (6.5 km/hr) and the throttle is closed, the PCM on NGC vehicles causes the transaxle to downshift to THIRD gear. After downshifting, the automatic speed control resumes normal operation. To ensure that an upshift is appropriate after the set speed is reached, the PCM on NGC vehicles waits until the speed control system opens the throttle at least 6 degrees before upshifting to OVERDRIVE again.

If the driver applies the brakes, canceling automatic speed control operation with the transaxle still in THIRD gear, the PCM on NGC vehicles maintains this gear until the driver opens the throttle at least 6 degrees to avoid an inappropriate upshift. The upshift is also delayed for 2.5 seconds after reaching the 6 degrees throttle opening in anticipation that the driver might open the throttle enough to require THIRD gear. This will avoid unnecessary and disturbing transmission cycling. If the automatic speed control RESUME feature is used after braking, the upshift is delayed until the set speed is achieved to reduce cycling and provide better response.

OPERATION - CHECKING FOR DIAGNOSTIC CODES

When trying to verify a speed control system electronic malfunction: Connect a DRBIII® scan tool if available to the data link connector. The connector is located near the steering column, and at lower edge of the dash panel.

A speed control malfunction may occur without a diagnostic code being indicated. For further information and usage of the DRBIII® scan tool and a more complete list of Diagnostic Trouble Code and No Trouble Codes, refer to the Powertrain Diagnostic Manual.

DIAGNOSIS AND TESTING - ROAD TEST

Perform a vehicle road test to verify reports of speed control system malfunction. The road test should include attention to the speedometer. Speedometer operation should be smooth and without flutter at all speeds.

Flutter in the speedometer indicates a problem which might cause surging in the speed control system. The cause of any speedometer problems should be corrected before proceeding. Refer to the Instrument Cluster for speedometer diagnosis.

If a road test verifies an inoperative system, and the speedometer operates properly, check for:

- A Diagnostic Trouble Code (DTC). If a DTC exists, conduct tests per the Powertrain Diagnostic Procedures manual.
- A misadjusted brake (stop) lamp switch. This could also cause an intermittent problem.
- Loose or corroded electrical connections at the servo. Corrosion should be removed from electrical terminals and a light coating of Mopar Multipurpose Grease, or equivalent, applied.
- Leaking vacuum reservoir.
- Loose or leaking vacuum hoses or connections.
- Defective one-way vacuum check valve.

SPEED CONTROL (Continued)

- Secure attachment at both ends of the speed control servo cable.
- Smooth operation of throttle linkage and throttle body air valve.
- Conduct electrical test at PCM.
- Failed speed control servo. Do the servo vacuum test.

CAUTION: When test probing for voltage or continuity at electrical connectors, care must be taken not to damage connector, terminals or seals. If these components are damaged, intermittent or complete system failure may occur.

CABLE

DESCRIPTION

The speed control servo cable is connected between the speed control vacuum servo diaphragm and the throttle body control linkage.

OPERATION

This cable causes the throttle control linkage to open or close the throttle valve in response to movement of the vacuum servo diaphragm.

REMOVAL

REMOVAL

(1) Remove the air cleaner lid, and makeup air hose.

(2) Remove the negative battery cable.

(3) Remove the engine cover and throttle control shield, if equipped.

(4) Remove two nuts attaching speed control cable and mounting bracket to servo (Fig. 6).

(5) Remove servo from the mounting bracket.

(6) Disconnect electrical connectors and vacuum hose.

(7) Remove retaining clip holding cable to servo (Fig. 3).

(8) Remove throttle cable clasp from the throttle body cam (Fig. 4).

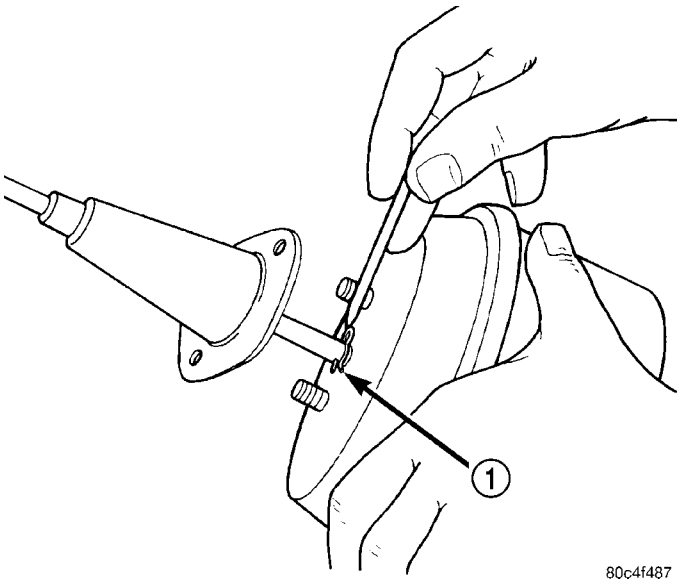

Fig. 3 Cable Clip

1 - HAIRPIN CLIP

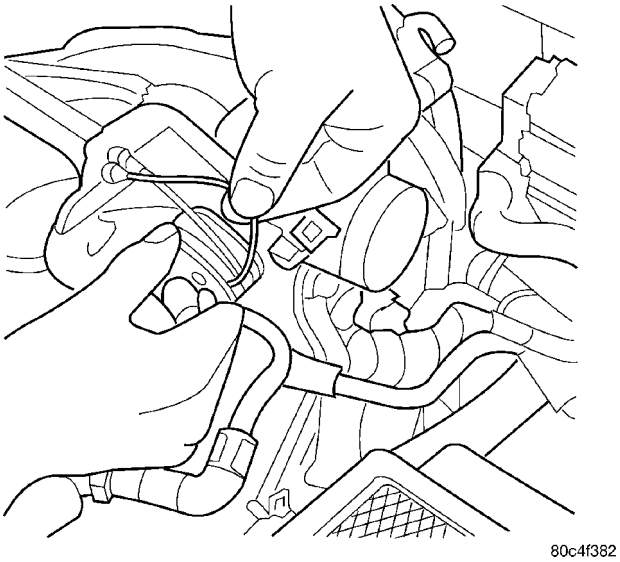

Fig. 4 Throttle Cable and Speed Control Cable

(9) Remove speed control cable from throttle cam by sliding clasp out hole used for throttle cable.

(10) Compress the retaining tabs on the cables and slide cables out of bracket (Fig. 5).

CABLE (Continued)

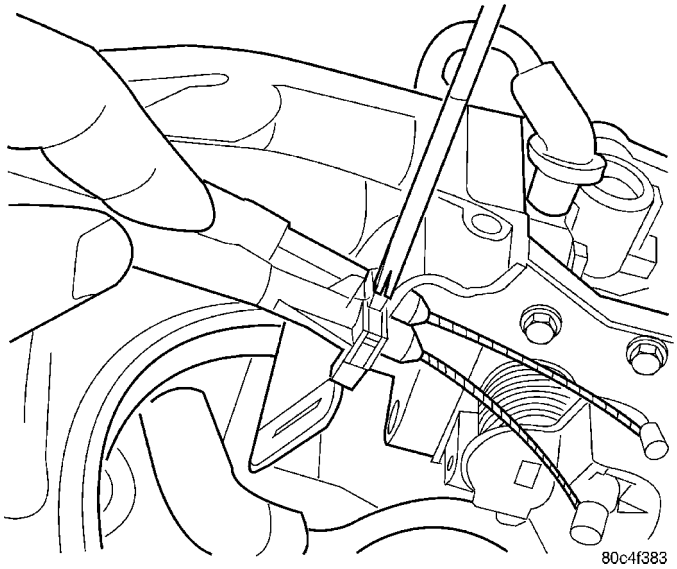

Fig. 5 Retaining Tabs

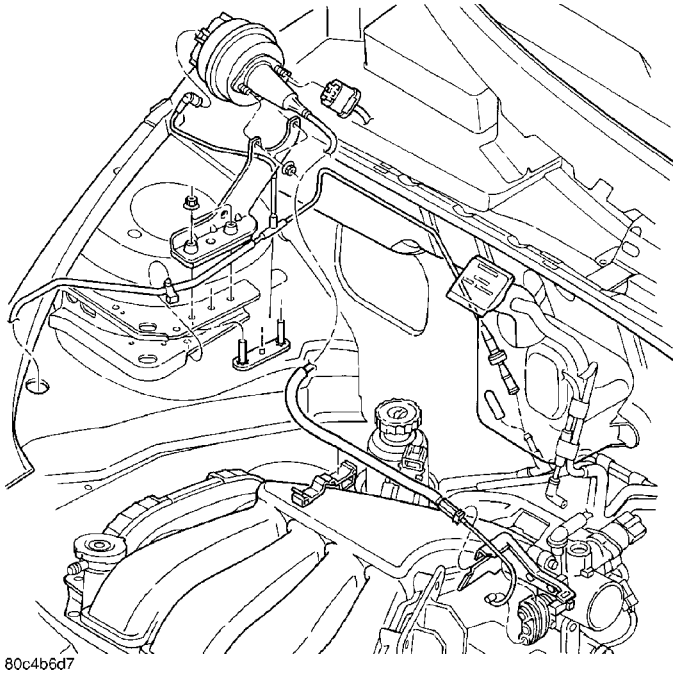

Fig. 6 Speed Control System

REMOVAL - 2.4L TURBO

(1) Disconnect the negative battery cable.

(2) Remove the throttle control shield (Fig. 7).

(3) Remove the speed control cable from the throttle body lever.

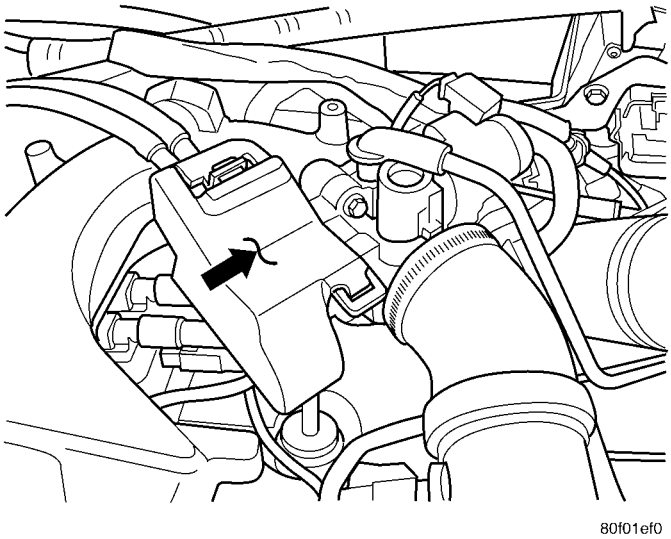

Fig. 7 THROTTLE CONTROL SHIELD

(4) Remove from throttle cable bracket by compressing the retaining tabs on the cable and slide cable out of the bracket (Fig. 8).

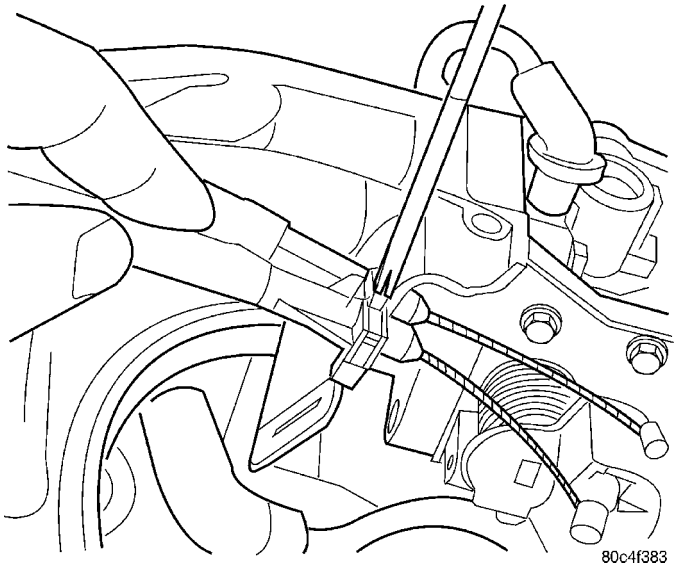

Fig. 8 Retaining Tabs

CABLE (Continued)

(5) Remove the vacuum line from the speed control servo (Fig. 9).

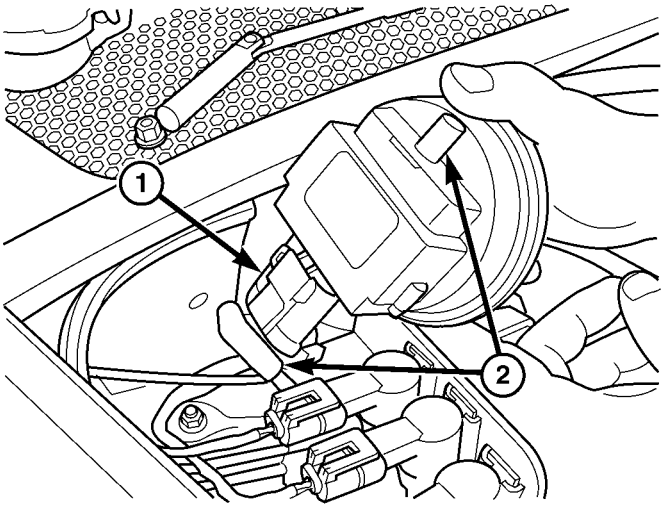

Fig. 9 VACUUM AND ELECTRICAL CONNECTION

1 - Electrical Connector
2 - Vacuum Line and Nipple

(6) Remove the 2 nuts from the speed control servo studs (Fig. 10).

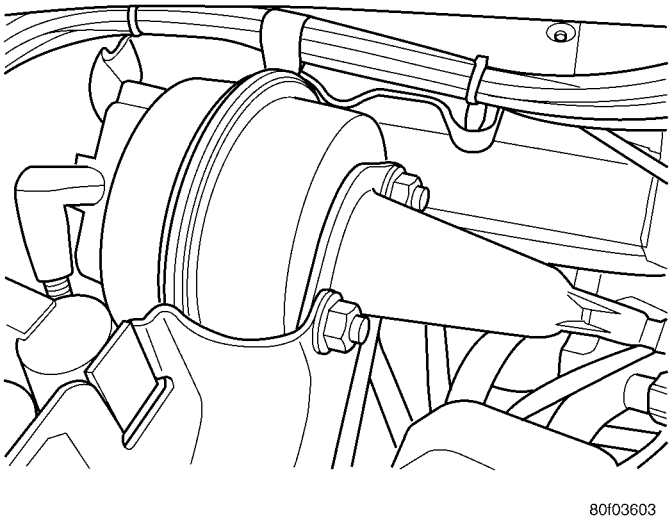

Fig. 10 SPEED CONTROL SERVO - 2.4L TURBO

(7) Push and pull up the speed control servo from the mounting bracket.

(8) Unlock and disconnect the electrical connector from the speed control servo (Fig. 9).

(9) Remove the 2 push clips and discard.

(10) Remove the retaining clip holding cable to servo (Fig. 11).

(11) Remove the cable.

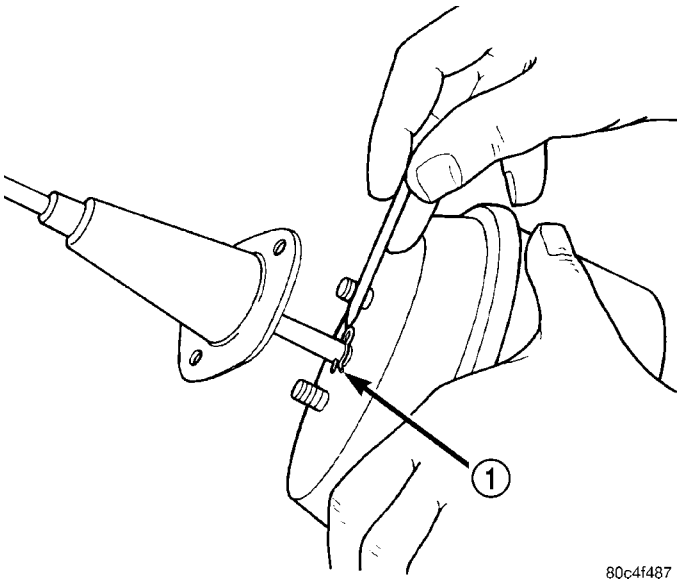

Fig. 11 Cable Clip

1 - HAIRPIN CLIP

INSTALLATION

INSTALLATION

(1) Install cable core wire through center hole on bracket, onto servo center post.

(2) Install retaining clip to cable at servo (Fig. 3).

(3) Slide cable bell housing over servo mounting studs through the bracket.

(4) Install 2 nuts, tighten to 7 N·m (60 ins. lbs.).

(5) Slide cables into throttle cable bracket and engage retaining tabs (Fig. 4).

(6) Rotate the throttle cam forward to the wide open position and install speed control cable clasp (Fig. 4).

(7) Rotate the throttle cam forward to the wide open position and install throttle cable clasp.

(8) Install engine cover and throttle control shield, if equipped.

(9) Install the negative battery cable.

(10) Install the air cleaner lid, makeup air hose.

INSTALLATION - 2.4L TURBO

(1) Install the cable.

(2) Install the retaining clip holding cable to servo (Fig. 11).

(3) Connect and Lock the electrical connector to the speed control servo (Fig. 9).

(4) Install the speed control servo to the mounting bracket.

(5) Install the 2 nuts to the speed control servo studs (Fig. 10) and tighten to 7 N·m(60 in. lbs.).

(6) Install the vacuum line to the speed control servo nipple (Fig. 9).

CABLE (Continued)

(7) Install speed control cable to throttle cable bracket (Fig. 8).

(8) Install the speed control cable to the throttle body lever.

(9) Install the throttle control shield (Fig. 7).

(10) Connect the negative battery cable.

SERVO

DESCRIPTION

The servo unit consists of a solenoid valve body, and a vacuum chamber. The solenoid valve body contains three solenoids:

- Vacuum
- Vent
- Dump

The vacuum chamber contains a diaphragm with a cable attached to control the throttle linkage.

OPERATION

The PCM controls the solenoid valve body. The solenoid valve body controls the application and release of vacuum to the diaphragm of the vacuum servo. The servo unit cannot be repaired and is serviced only as a complete assembly.

Power is supplied to the servo by the PCM through the brake switch. The PCM controls the ground path for the vacuum and vent solenoids.

The dump solenoid is energized anytime it receives power. If power to the dump solenoid is interrupted, the solenoid dumps vacuum in the servo. This provides a safety backup to the vent and vacuum solenoids.

The vacuum and vent solenoids must be grounded by the PCM to operate. When the PCM grounds the vacuum servo solenoid, the solenoid allows vacuum to enter the servo and pull open the throttle plate using the cable. When the PCM breaks the ground, the solenoid closes and no more vacuum is allowed to enter the servo. The PCM also operates the vent solenoid via ground. The vent solenoid opens and closes a passage to bleed or hold vacuum in the servo as required.

The PCM cycles the vacuum and vent solenoids to maintain the set speed, or to accelerate and decelerate the vehicle. To increase throttle opening, the PCM grounds the vacuum and vent solenoids. To decrease throttle opening, the PCM removes the grounds from the vacuum and vent solenoids.

REMOVAL

REMOVAL

(1) Remove the air cleaner lid, and makeup air hose.

(2) Remove the negative battery cable.

(3) Remove two nuts attaching speed control cable and mounting bracket to servo (Fig. 12).

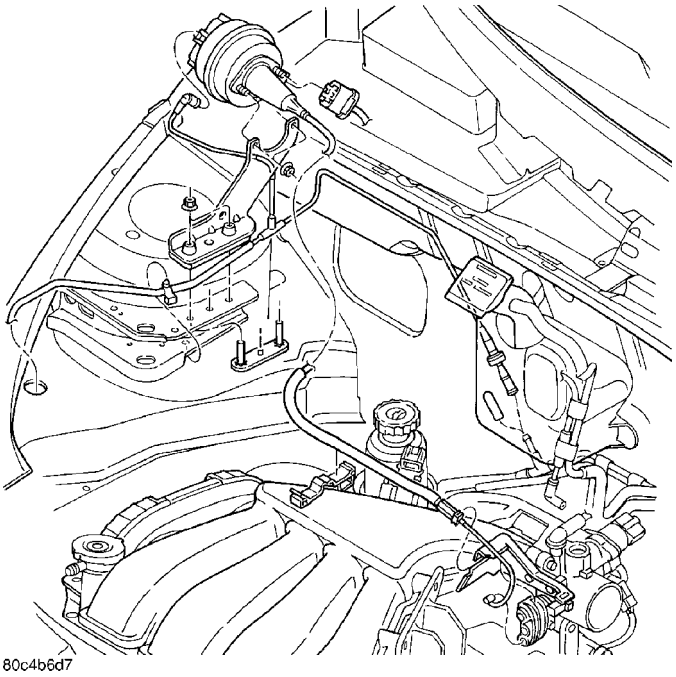

Fig. 12 Speed Control System

(4) Remove servo from the mounting bracket.

(5) Disconnect electrical connectors and vacuum hose.

(6) Remove the engine cover.

(7) Remove cable from throttle cam. Refer to Speed Control Servo Cable Removal/Installation in this section.

(8) Remove the 2 push nuts and discard.

(9) Remove clip attaching cable to servo (Fig. 13).

REMOVAL - 2.4L TURBO

(1) Disconnect the negative battery cable.

(2) Remove the throttle control shield (Fig. 7).

(3) Remove the speed control cable from the throttle body lever.

(4) Remove the vacuum line from the speed control servo (Fig. 9).

(5) Remove the 2 nuts from the speed control servo studs (Fig. 10).

SERVO (Continued)

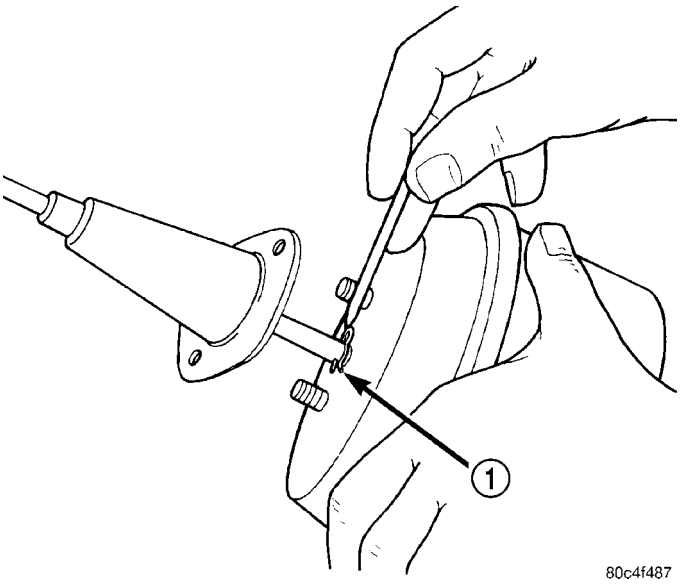

Fig. 13 Attaching Clip

1 - HAIRPIN CLIP

(6) Push and pull up the speed control servo from the mounting bracket.

(7) Unlock and disconnect the electrical connector from the speed control servo (Fig. 10).

(8) Remove the 2 push clips and discard.

(9) Remove the retaining clip holding cable to servo (Fig. 11).

INSTALLATION

INSTALLATION

(1) Install hairpin clip to servo and cable (Fig. 13).

(2) Install servo studs through cable bell and then the bracket.

(3) Install nuts, tighten to 7 N·m (60 in. lbs.).

(4) Install speed control cable to throttle cam. Refer to Speed Control Servo Cable Removal/Installation in this section.

(5) Connect electrical connector.

(6) Connect the vacuum hose to servo.

(7) Install the engine cover.

(8) Install the negative battery cable.

(9) Install the air cleaner lid, and makeup air hose.

INSTALLATION - 2.4L TURBO

(1) Install the retaining clip holding cable to servo (Fig. 11).

(2) Connect and lock the electrical connector to the speed control servo (Fig. 10).

(3) Install the speed control servo to the mounting bracket.

(4) Install the 2 nuts from the speed control servo studs (Fig. 10).

(5) Install the vacuum line to the speed control servo (Fig. 9).

(6) Install the speed control cable to the throttle body lever.

(7) Install the throttle control shield (Fig. 7).

(8) Connect the negative battery cable.

SWITCH

REMOVAL

The speed control switches is mounted in the steering wheel and wired through the clock spring device under the airbag module (Fig. 14).

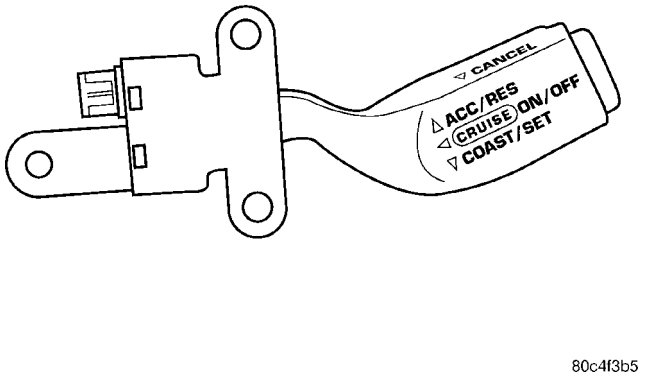

Fig. 14 Speed Control Switch

WARNING: IF REMOVAL OF AIRBAG MODULE IS NECESSARY, REFER TO THE RESTRAINT SYSTEMS.

(1) Remove the air cleaner lid, disconnect the inlet air temperature sensor and makeup air hose.

(2) Remove the negative battery cable.

(3) Turn off ignition.

(4) Remove air bag, refer to the Restraint systems section.

(5) Remove the top mounting screw (Fig. 15).

(6) Rotate steering wheel so that the switch is in the 6 o'clock position. Remove 2 screws from the back side of the speed control switch.

(7) Disconnect the electrical connector.

(8) Remove switch (Fig. 16).

INSTALLATION

The speed control switch is mounted in the steering wheel and wired through the clock spring device under the airbag module (Fig. 14).

WARNING: IF REMOVAL OF AIRBAG MODULE IS NECESSARY, REFER TO THE RESTRAINT SYSTEMS.

SWITCH (Continued)

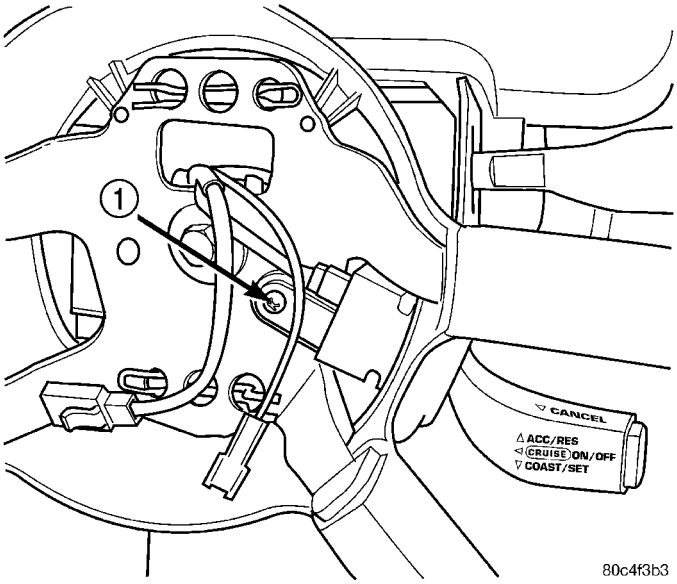

Fig. 15 Switch Top Mounting Screw

1 - TOP MOUNTING SCREW

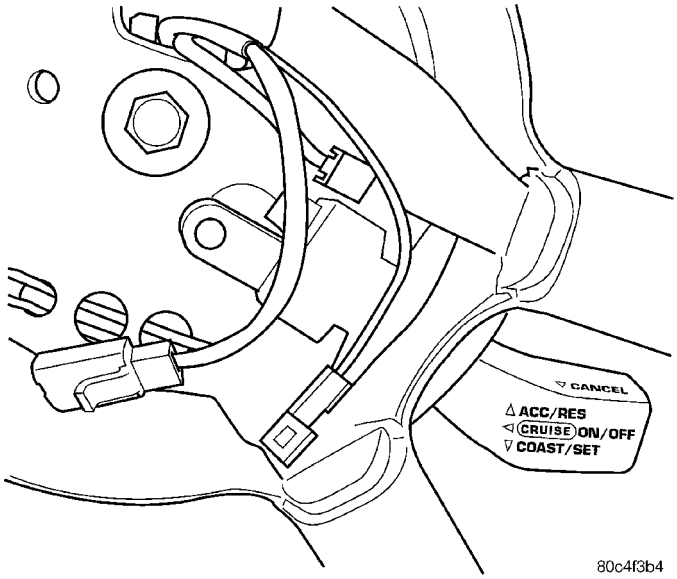

Fig. 16 Switch Removal

(1) Connect the electrical connector.

(2) Install switch (Fig. 16) and tighten the screws to 1.6 N·m (15 ins. lbs.). Make sure rubber seal is in place around switch.

(3) Install airbag, refer to the Restraint Systems section.

(4) Install the negative battery cable.

(5) Install the air cleaner lid, connect the inlet air temperature sensor and makeup air hose.

VACUUM RESERVOIR

DESCRIPTION

The vacuum reservoir is located in the right front fender well on the frame rail (Fig. 17). It is made of plastic.

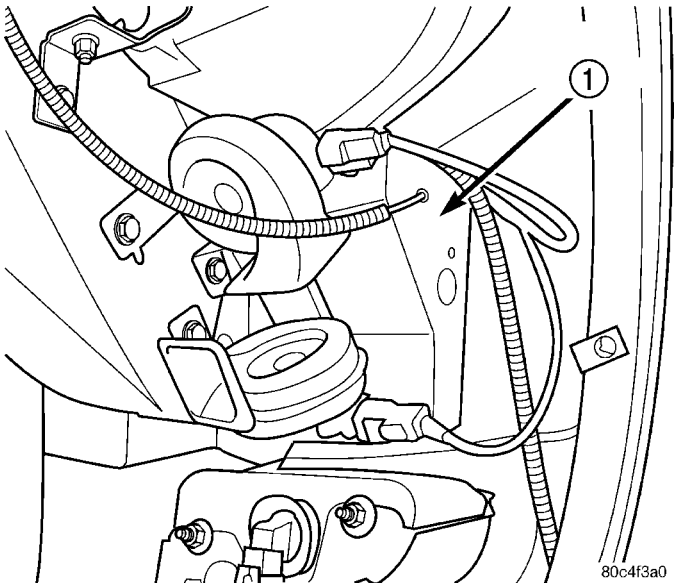

Fig. 17 Vacuum Reservoir

1 - VACUUM RESERVOIR

OPERATION

The reservoir stores engine vacuum. Manifold vacuum is supplied from the brake booster check valve. The speed control vacuum supply hose has a check valve at the source (brake booster) to maintain the highest available vacuum level in the servo, reservoir and vacuum hoses. When engine vacuum drops, as in climbing a grade while driving, the reservoir supplies the vacuum needed to maintain proper speed control operation. The vacuum reservoir cannot be repaired and must be replaced if faulty.

VACUUM RESERVOIR (Continued)

REMOVAL

The vacuum reservoir is located in the right front fender well on the frame rail (Fig. 19). It is made of plastic.

(1) Remove the air cleaner lid, disconnect the inlet air temperature sensor and makeup air hose.

(2) Remove the negative battery cable.

(3) Raise vehicle and support.

(4) Remove the right front wheel.

(5) Remove the front half of the inner splash shield and relocate rearward (Fig. 18).

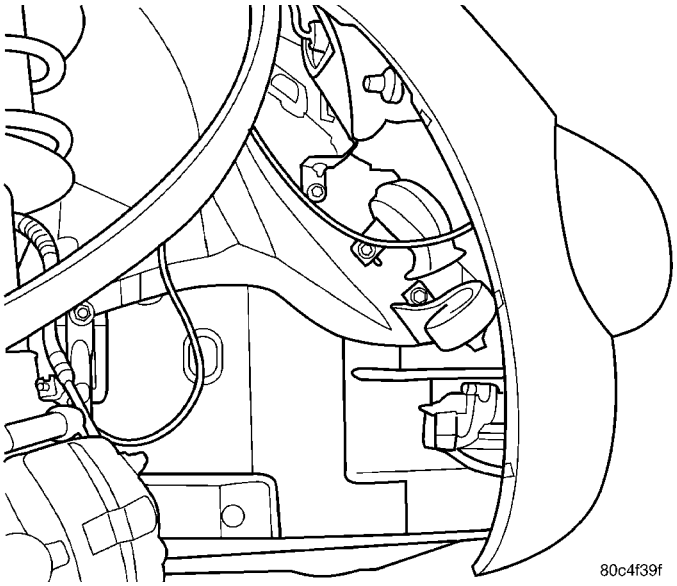

Fig. 18 Inner Splash Shield

(6) Remove the 2 screws from vacuum reservoir (Fig. 19).

(7) Disconnect vacuum hose from reservoir (Fig. 20).

INSTALLATION

The vacuum reservoir is located in the right front fender well on the frame rail (Fig. 19). It is made of plastic.

(1) Connect hoses to reservoir.

(2) Install reservoir and tighten screws to 5 N·m (45 ins. lbs.) (Fig. 19).

(3) Install the inner splash shield (Fig. 18).

(4) Lower vehicle.

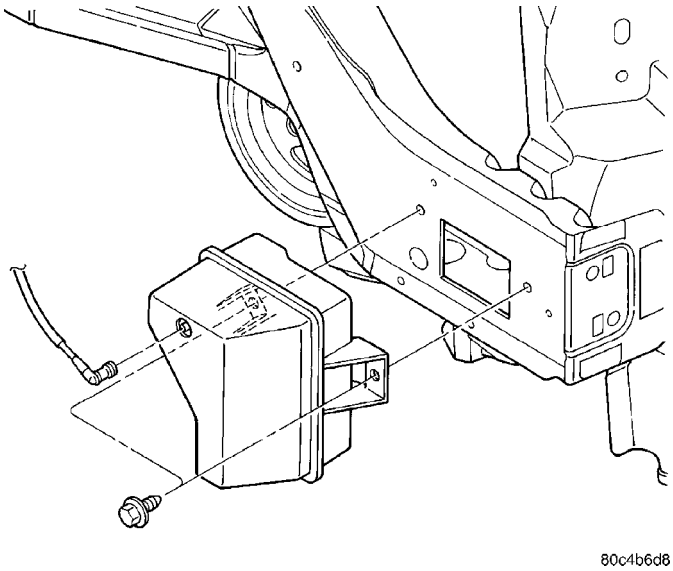

Fig. 19 Reservoir Mounting Screws

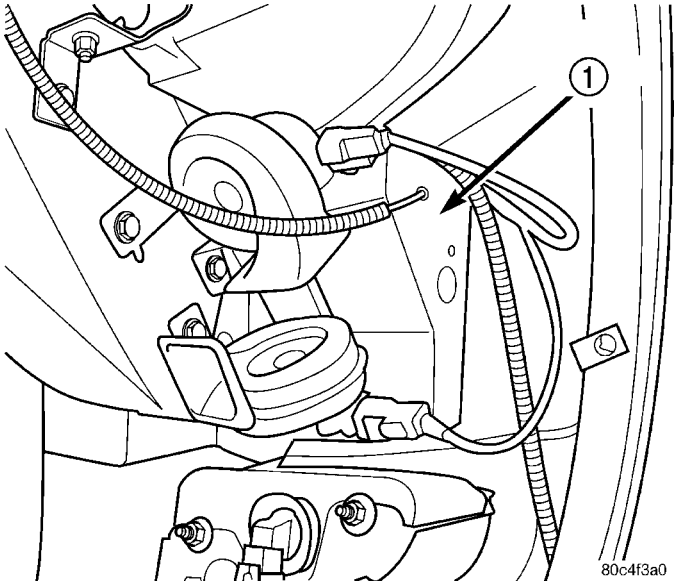

Fig. 20 Vacuum Reservoir

1 - VACUUM RESERVOIR

(5) Install the negative battery cable.

(6) Install the air cleaner lid, connect the inlet air temperature sensor and makeup air hose.

VEHICLE THEFT SECURITY

DESCRIPTION

VEHICLE THEFT SECURITY SYSTEM

The Vehicle Theft/Security System (VTSS) is designed to protect against whole vehicle theft. The system monitors vehicle doors, liftgate, and ignition for unauthorized operation.

The VTSS activates:

- Sounding of the horn.
- Flashing of the park lamps.
- Flashing of the headlamps.

The vehicle theft security system contains a built-in tamper alert feature. This feature is designed to notify the driver that the system had been activated during its armed state. When the vehicle is disarmed, 3 horn pulses will be followed by the initial disarming pulse letting the driver know the system had been activated.

VEHICLE THEFT SECURITY SYSTEM - EXPORT

Some vehicles are equipped with a Premium Vehicle Theft Security System (VTSS). The premium VTSS is designed to protect against whole vehicle theft and the loss of its contents. This system monitors vehicle doors, hood, liftgate and ignition key cylinders for unauthorized operation, as well as monitoring any movement inside the cabin when the intrusion sensor is armed.

Some vehicles are equipped with a standard vehicle theft security system. This system is designed to protect against whole vehicle theft. This system monitors the vehicle doors, liftgate, and ignition key cylinders for unauthorized operation.

SENTRY KEY IMMOBILIZER SYSTEM

The Sentry Key Immobilizer System (SKIS) is available as a factory-installed option on this vehicle. It is designed to provide passive protection against unauthorized vehicle use by disabling the engine, after two (2) seconds of running, whenever an invalid key is used to start the vehicle. The SKIS is active whenever the ignition is on and does not require any customer intervention. The primary components of the system are the Sentry Key Immobilizer Module (SKIM), Sentry Key (ignition key with a transponder molded into the head), indicator light, and the Powertrain Control Module (PCM). The SKIM is mounted to the steering column with the molded, integral antenna mounted on the trim ring surrounding the ignition lock cylinder. The indicator light, is located in the instrument cluster.

OPERATION

VEHICLE THEFT SECURITY SYSTEM

The system is armed when the vehicle is locked using the:

- Power door lock switches.
- Remote Keyless Entry (RKE) transmitter.
- Key cylinder switches.

VEHICLE THEFT SECURITY (Continued)

After the vehicle is locked and the last door is closed, the circular red VTSS indicator in the instrument cluster will flash quickly for 16 seconds, indicating that arming is in progress. If no monitored systems are activated during this period the system will arm. After 16 seconds, the LED will continue to flash at a slower rate indicating the system is armed.

If the VTSS indicator does not illuminate at all upon door closing it indicates that the system is not arming.

VTSS disarming occurs upon normal vehicle entry by unlocking either door via the key cylinders or RKE transmitter, or by starting the vehicle with a valid Sentry Key. This disarming will also halt the alarm once it has been activated.

A tamper alert exists to notify the driver that the system had been activated. This alert consists of 3 horn pulses when the vehicle is disarmed.

The VTSS will not arm by mechanically locking the vehicle doors. This will manually override the system.

The VTSS functionality is contained within the Remote Keyless Entry (RKE) Module, sometimes referred to as the Alarm Remote Keyless Entry Module (ARKEM) (Refer to 8 - ELECTRICAL/POWER LOCKS - DESCRIPTION).

TRIGGERING THE VTSS

ARMING THE VTSS

Locking the power door switch and closing the door or the keyless transmitter will arm the system, or locking any door or liftgate with the key cylinder switch.

SETTING OFF THE VTSS Any of the following actions will trigger the system:

(1) Opening any door or liftgate.

NOTE: Only EXPORT alarm systems will include a hood ajar switch, motion sensor, and decklid ajar switch.

(2) Turning the ignition to the ON position with an invalid key.

VEHICLE THEFT SECURITY SYSTEM - EXPORT

In the event the Premium VTSS is triggered, the VTSS siren will sound and the turn indicator lamps will flash on the premium security system. The premium system cannot be disarmed via the key cylinders.

In the event the Standard VTSS is triggered, the VTSS will sound the vehicle horn and flash the headlamp and park lamps in a alternating fashion.

The VTSS and RKE system receives signals from the hand-held key fob or transmitter. European market vehicles use 433 MHz frequency. Japan market vehicles use 268 MHz frequency.

SENTRY KEY IMMOBILIZER SYSTEM

The SKIS includes keys from the factory which are pre-programmed. Each SKIM will recognize a maximum of eight Sentry Keys. If the customer would like to own additional keys other than those provided with the vehicle, they can be purchased from any authorized dealer. These keys must be programmed to the SKIM on the vehicle in order for the system to recognize them as valid keys. This can be done by the dealer with a DRB III® scan tool or by a customer if this feature is available in their market and they have two (2) valid keys already available to them. Refer to the Service Procedures portion of this system for additional details. The SKIS performs a self-test each time the ignition switch is turned to the ON position and will store Diagnostic Trouble Codes (DTC's) if a system malfunction is detected. The DTC's can be retrieved using a DRB III® scan tool. The SKIS can be diagnosed using the proper Powertrain Diagnostic Procedures manual.

DIAGNOSIS AND TESTING - SENTRY KEY IMMOBILIZER SYSTEM

WARNING: ON VEHICLES EQUIPPED WITH AIRBAGS, (Refer to 8 - ELECTRICAL/RESTRAINTS - WARNING). FAILURE TO TAKE THE PROPER PRECAUTIONS COULD RESULT IN ACCIDENTAL AIRBAG DEPLOYMENT AND POSSIBLE PERSONAL INJURY.

NOTE: The following tests may not prove conclusive in the diagnosis of this system. The most reliable, efficient, and accurate means to diagnose the Sentry Key Immobilizer System (SKIS) involves the use of a DRB lll® scan tool and the proper Powertrain Diagnostic Procedures manual.

The Sentry Key Immobilizer System (SKIS) and the Programmable Communication Interface (PCI) bus network should be diagnosed using a DRB lll® scan tool. The DRB lll® will allow confirmation that the PCI bus is functional, that the Sentry Key Immobilizer Module (SKIM) is placing the proper messages on the PCI bus, and that the Powertrain Control Module (PCM) and the instrument cluster are receiving the PCI bus messages. Refer to the proper Powertrain Diagnostic Procedures manual. Refer to Wiring Diagrams for complete circuit descriptions and diagrams.

VEHICLE THEFT SECURITY (Continued)

(1) Check the fuses in the fuse block. If OK, go to Step 2. If not OK, repair the shorted circuit or component as required and replace the faulty fuse.

(2) Disconnect and isolate the battery negative cable (Fig. 1). Unplug the wire harness connector at the SKIM. Check for continuity between the ground circuit cavity of the SKIM wire harness connector and a good ground. There should be continuity. If OK, go to Step 3. If not OK, repair the open circuit to ground as required.

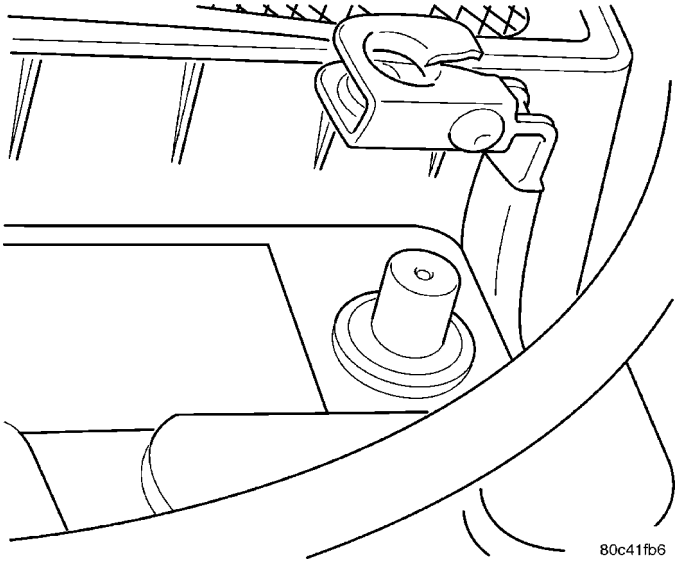

Fig. 1 BATTERY NEGATIVE CABLE - REMOVE/ INSTALL

(3) Connect the battery negative cable. Check for battery voltage at the fused B(+) circuit cavity of the SKIM wire harness connector. If OK, go to Step 4. If not OK, repair the open circuit to the fuse in the fuse block as required.

(4) Turn the ignition switch to the ON position. Check for battery voltage at the fused ignition switch output (run/start) circuit cavity of the SKIM wire harness connector. If OK, use a DRB lll® scan tool and the proper Powertrain Diagnostic Procedures manual to complete the diagnosis of the SKIS. If not OK, repair the open circuit to the fuse in the fuse block as required.

GENERAL TROUBLESHOOTING TIPS

(1) Using a DRB III® scan tool, read and record the faults as they exist in the module when you first start your analysis of the vehicle. It is important to document these faults because the SKIM does not differentiate between historical faults (those faults that occurred in the past) and active faults (those faults that are present now). If this problem turns out to be an intermittent condition, this information may become very valuable to your analysis.

(2) Using a DRB III® scan tool, erase the faults in the Sentry Key Immobilizer Module (SKIM).

(3) Turn the ignition off and back on again.

(4) Using a DRB III® scan tool, read the faults now listed in the Sentry Key Immobilizer Module (SKIM).

(5) Using the fault information you now have, refer to the proper Powertrain Diagnostic Procedures manual for additional specific steps.

STANDARD PROCEDURE

STANDARD PROCEDURE - RKE/VTSS CONFIGURING A NEW MODULE

To switch operating modes or to configure a new module, a DRB lll® scan tool must be used.

(1) Hook up the DRB lll® scan tool to the Data Link Connector (DLC).

(2) With the key in the ignition, turn the key to the RUN position.

(3) After the DRB lll® scan tool initialization, perform the following:

(a) Select “Theft Alarm.”

(b) Select “VTSS.”

(c) Select “Miscellaneous.”

(4) Once in the “Miscellaneous” screen:

(a) If you wish to configure a new module, select “Configure Module.”

STANDARD PROCEDURE - SENTRY KEY IMMOBILIZER SYSTEM INITIALIZATION

The Sentry Key Immobilizer System (SKIS) initialization should be performed following a Sentry Key Immobilizer Module (SKIM) replacement.

It can be summarized by the following:

(1) Obtain the vehicles unique PIN number assigned to it’s original SKIM from the vehicle owner, the vehicle’s invoice or from Chrysler’s Customer Center.

(2) With the DRB lll® scan tool, select “Theft Alarm,” “SKIM,” Miscellaneous.” Select “SKIM Module Replaced” function and the DRB lll® will prompt you through the following steps.

(3) Enter secured access mode using the unique four digit PIN number.

(4) Program the vehicle’s VIN number into the SKIM’s memory.

(5) Program the country code into the SKIM’s memory.

VEHICLE THEFT SECURITY (Continued)

(6) Transfer the vehicle's unique Secret Key data from the PCM. This process will require the SKIM to be in **secured access mode**. The PIN number must be entered into the DRB lll® before the SKIM will enter **secured access mode**. Once **secured access mode** is active, the SKIM will remain in that mode for 60 seconds.

(7) Program all customer keys into the SKIM's memory. This required that the SKIM be in **secured access mode** The SKIM will immediately exit **secured access mode** after each key is programmed.

NOTE: If a PCM is replaced, the unique "Secret Key" data must be transferred from the SKIM to the PCM. This procedure requires the SKIM to be placed in SECURED ACCESS MODE using the four digit PIN code.

DOOR CYLINDER LOCK SWITCH

REMOVAL

(1) Open hood.

(2) Disconnect and isolate the battery negative cable (Fig. 1).

(3) Remove front door trim panel (Refer to 23 - BODY/DOOR - FRONT/TRIM PANEL - REMOVAL).

(4) Remove door cylinder lock switch from door lock cylinder (Fig. 2).

(5) Remove the switch from the inside of the door by pulling the switch and attached wires out of the door.

(6) Cut the two wires leading to the bad switch, at least three inches from where the wires enter the switch.

INSTALLATION

(1) Splice in the new switch. Refer to Wiring Diagrams for splicing information.

(2) Route the door cylinder lock switch inside the door panel.

(3) Install door cylinder lock switch on rear of door lock cylinder (Fig. 2).

(4) Install the front door trim panel (Refer to 23 - BODY/DOOR - FRONT/TRIM PANEL - INSTALLATION).

(5) Connect the battery negative cable (Fig. 1).

(6) Close hood.

(7) Verify vehicle and system operation.

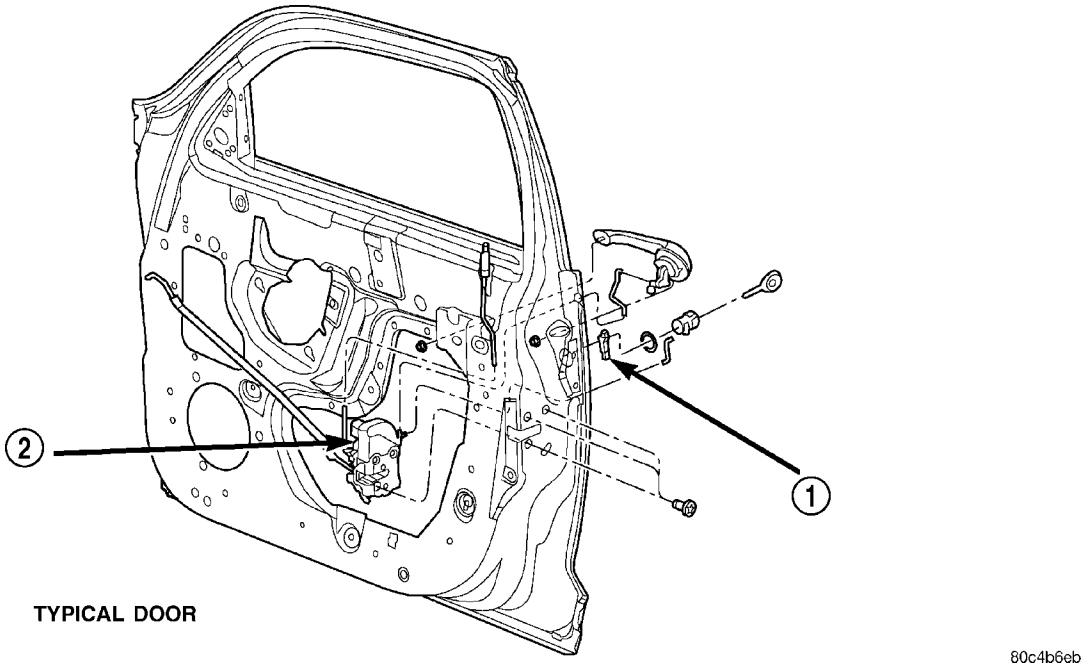

Fig. 2 DOOR CYLINDER LOCK SWITCH - REMOVE/INSTALL

1 - DOOR CYLINDER LOCK SWITCH
2 - DOOR LOCK MOTOR

HOOD AJAR SWITCH - EXPORT

REMOVAL

(1) Open hood.

(2) Disconnect and isolate the battery negative cable (Fig. 1).

(3) Disconnect wire harness connector from hood ajar switch.

(4) Firmly press tangs on the bottom side of the switch together and push up through bracket (Fig. 3).

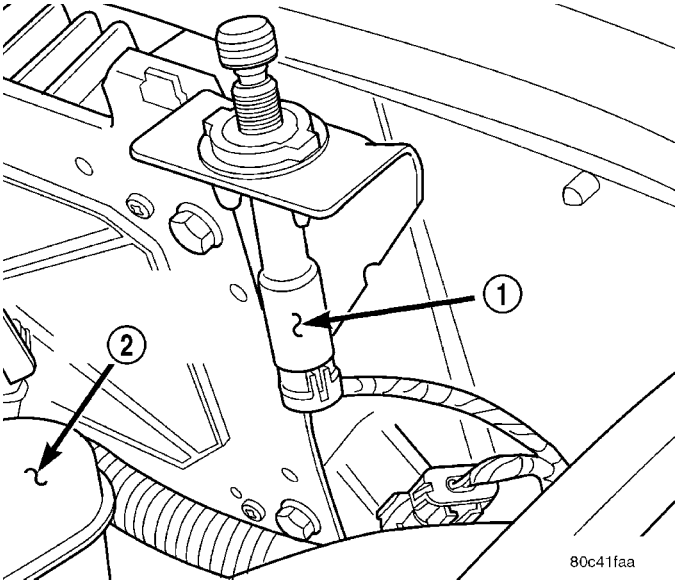

Fig. 3 HOOD AJAR SWITCH LOCATION

1 - HOOD AJAR SWITCH CONNECTOR
2 - BRAKE FLUID RESERVOIR

(5) Remove switch from vehicle.

INSTALLATION

(1) Firmly press hood ajar switch through bracket (Fig. 3).

(2) Connect wire harness connector to hood ajar switch.

(3) Connect the battery negative cable (Fig. 1).

(4) Close hood.

(5) Verify vehicle and system operation.

LIFTGATE CYLINDER LOCK SWITCH

REMOVAL

(1) Open hood.

(2) Disconnect and isolate the battery negative cable (Fig. 1).

(3) Remove the liftgate trim panel (Refer to 23 - BODY/DECKLID/HATCH/LIFTGATE/TAILGATE/ TRIM PANEL - REMOVAL).

(4) Remove the liftgate cylinder U-bracket by sliding it out.

(5) Remove switch E-clip and disconnect connector.

(6) Remove liftgate cylinder lock switch from liftgate lock cylinder (Fig. 4) by gently unsnapping.

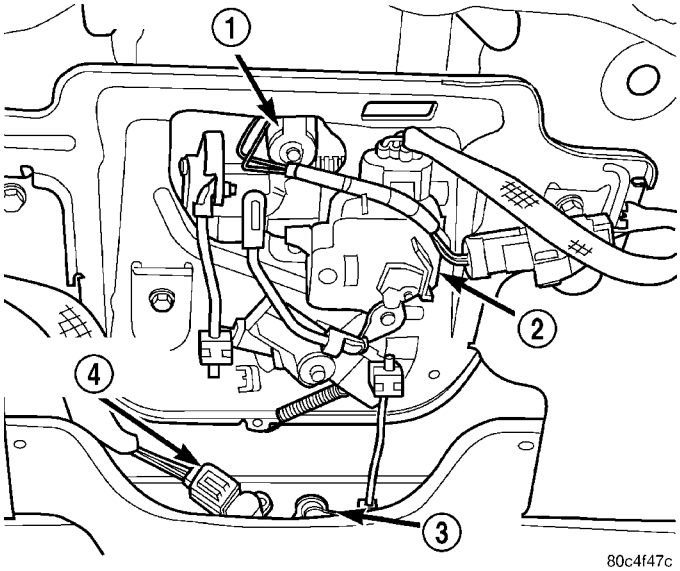

Fig. 4 LIFTGATE CYLINDER LOCK SWITCH LOCATION

1 - LIFTGATE CYLINDER LOCK SWITCH
2 - LIFTGATE LOCK MOTOR
3 - LATCH ASSEMBLY
4 - LIFTGATE AJAR SWITCH

INSTALLATION

(1) Install liftgate cylinder lock switch on rear of liftgate lock cylinder without rotating the switch (Fig. 2).

(2) Install the liftgate cylinder U-bracket by sliding it in.

(3) Install switch E-clip and connector.

(4) Install the liftgate trim panel (Refer to 23 - BODY/DECKLID/HATCH/LIFTGATE/TAILGATE/ TRIM PANEL - INSTALLATION).

(5) Connect the battery negative cable (Fig. 1).

(6) Close hood.

(7) Verify vehicle and system operation.

SKIS INDICATOR LAMP

DESCRIPTION

The Sentry Key Immobilizer System (SKIS) uses the Vehicle Theft Security System (VTSS) indicator LED to give an indication when the SKIS is faulty or when the vehicle has been immobilized due to the use of an invalid ignition key. The LED is controlled by the instrument cluster circuitry based upon messages received from the Sentry Key Immobilizer Module (SKIM).

OPERATION

The SKIM sends messages to the instrument cluster, to turn the LED on for about three seconds when the ignition switch is turned to the ON position as a bulb test. After completion of the bulb test, the SKIM sends PCI bus messages to keep the LED off for a duration of about one second. Then the SKIM sends messages to the instrument cluster circuitry to turn the LED on or off based upon the results of the SKIS self-tests. If the VTSS indicator LED comes on and stays on after the bulb test, it indicates that the SKIM has detected a system malfunction and/or that the SKIS has become inoperative. If the SKIM detects an invalid key when the ignition switch is turned to the ON position, it sends messages to the instrument cluster to flash the VTSS indicator LED.

The SKIM can also send messages to the instrument cluster to flash the LED and to generate a single audible chime tone. These functions serve as an indication to the customer that the SKIS has been placed in its “Customer Learn” programming mode. See Sentry Key Immobilizer System Transponder Programming in this group for more information on the “Customer Learn” programming mode.

The VTSS indicator LED uses a Light Emitting Diode (LED) on the instrument cluster electronic circuit board. It is not serviceable separate from the instrument cluster assembly. If the VTSS indicator LED comes on and stays on after the bulb test function, diagnosis of the SKIS should be performed with a DRB lll® scan tool and the proper Powertrain Diagnostic Procedures manual.

TRANSPONDER KEY

DESCRIPTION

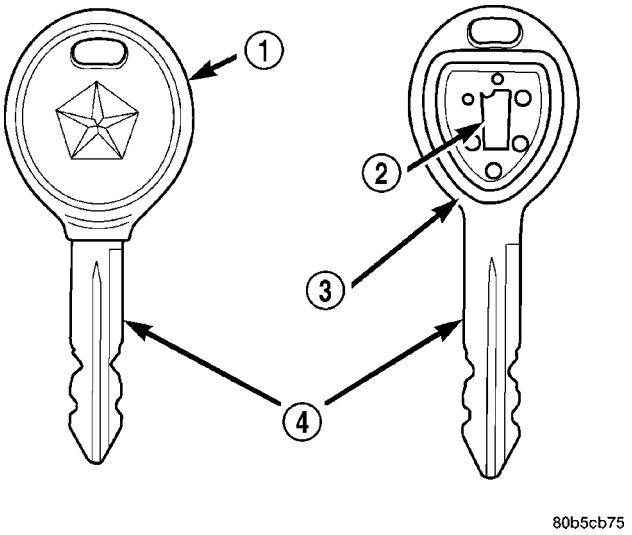

Fig. 5 SENTRY KEY IMMOBILIZER TRANSPONDER

1 - MOLDED CAP
2 - TRANSPONDER
3 - MOLDED CAP REMOVED
4 - SENTRY KEY

The Sentry Key Immobilizer System (SKIS) uses a transponder chip that is integral to each ignition key (Fig. 5) to communicate with the Sentry Key Immobilizer Module (SKIM). Ignition keys are supplied with the vehicle when it is shipped from the factory. The transponder chip is undermolded within the head of the key. This undermold is hidden beneath an overmolded rubber cap.

OPERATION

Each Sentry Key transponder has a unique transponder identification code programmed into it by the manufacturer. The Sentry Key Immobilizer Module (SKIM) has a unique “Secret Key” code programmed into it by the manufacturer. When a Sentry Key transponder is programmed into the memory of the SKIM, the SKIM learns the transponder identification code from the transponder, and the transponder learns the “Secret Key” code from the SKIM. Each of these codes is stored within the transponder and in the nonvolatile memory of the SKIM. Therefore, blank keys for the SKIS must be programmed by and into the SKIM, in addition to being cut to match the mechanical coding of the ignition lock cylinder. See Sentry Key Immobilizer System Transponder Programming in this section for more information.

TRANSPONDER KEY (Continued)

The Sentry Key's transponder is within the range of the SKIM's transceiver antenna ring when it is inserted into the ignition lock cylinder. When the ignition switch is turned to the ON position, the SKIM communicates with the Sentry Key via a radio frequency (RF) signal. The SKIM determines if a valid key is present based on the information it receives from the Sentry Key. If a valid key is detected, that fact is communicated to the PCM via the PCI bus and the vehicle is allowed to continue running. If an invalid key is received by the PCM or no status at all is communicated, the vehicle will stall after two (2) seconds of running. The indicator light will be flashing at this point. The Sentry Key's transponder can not be repaired. If it is faulty or damaged, it must be replaced.

STANDARD PROCEDURE - TRANSPONDER PROGRAMMING

USING A DRB III® SCAN TOOL

All Sentry Keys included with the vehicle are preprogrammed to work with the Sentry Key Immobilizer System (SKIS) when it is shipped from the factory. The Sentry Key Immobilizer Module (SKIM) can be programmed to recognize up to a total of eight Sentry Keys. When programming a blank Sentry Key transponder, the key must first be cut to match the ignition lock cylinder of the vehicle for which it will be used. The vehicle's four digit PIN code will be required to complete this task since you will need it to enter the Secured Access Mode in the SKIM. The following steps must be completed using a DRB III® scan tool:

(1) Insert the blank key into the ignition and turn it to the RUN position.

(2) Using a DRB III® scan tool, select "Theft Alarm," "SKIM," "Miscellaneous," and then "Program Ignition Key."

(3) Enter the four digit PIN code using the DRB III® scan tool. When programming is completed, the SKIM will exit Secured Access Mode and the DRB III® scan tool will display the results of your attempt to program the key. One of five distinct results may be displayed. All five are listed below:

- **"Programming Successful"** is displayed if the Sentry Key programming is successful.
- **"Learned Key in Ignition"** is displayed if the key in the ignition has already been programmed into that vehicle's SKIM.
- **"Eight Keys Already Learned (At The Maximum) Programming Not Done"** is displayed if eight keys have already been programmed into the SKIM. In this case, if a new key needs to be added due to a lost or defective key, the "Erase All Keys" command (which requires entering the Secured Access Mode) has to be performed. Following the "Erase All Keys" command, all keys that will be used to operate the vehicle **MUST** be reprogrammed to the SKIM.
- **"Programming Not Attempted"** is displayed after an "Erase All Keys" function is executed.
- **"Programming Key Failed"** is displayed if further diagnosis is required.

To learn additional keys, turn the ignition OFF, remove the learned key, insert the next new blank key, and repeat the steps from the beginning.

"CUSTOMER LEARN" MODE

This feature is only available on domestic vehicles or those which have a U.S. country code designator. This procedure requires access to at least two valid Sentry Keys. If two valid Sentry Keys are not available, Sentry Key programming will require the use of a DRB III® scan tool.

The steps required to program Sentry Keys with two valid Sentry Keys follows:

(1) Obtain the blank Sentry Key(s) that need to be programmed. Cut the keys to match the ignition lock cylinder mechanical key codes.

(2) Insert one of the two valid Sentry Keys into the ignition switch and turn the ignition switch to the ON position.

(3) After the ignition switch has been in the ON position for longer than three seconds, but no more than fifteen seconds, cycle the ignition switch back to the OFF position. Replace the first valid Sentry Key in the ignition lock cylinder with the second valid Sentry Key and turn the ignition switch back to the ON position. The second valid Sentry Key must be inserted, and the ignition key to the ON position, within 15 seconds of removing the first valid Sentry key.

(4) About ten seconds after the completion of Step 3, the indicator light will start to flash and a single audible chime tone will sound to indicate that the system has entered the "Customer Learn" programming mode.

(5) Within sixty seconds of entering the "Customer Learn" programming mode, turn the ignition switch to the OFF position, replace the valid Sentry Key with a blank Sentry Key transponder, and turn the ignition switch back to the ON position.

TRANSPONDER KEY (Continued)

(6) About ten seconds after the completion of Step 5, a single audible chime tone will sound and the indicator light will stop flashing and stay on solid for three seconds and then turn off to indicate that the blank Sentry Key has been successfully programmed. The SKIS will immediately exit the ″Customer Learn″ programming mode and the vehicle may be started using the newly programmed Sentry Key.

These steps must be completed in their entirety for each additional Sentry Key to be programmed. If any of the above steps are not completed in the given sequence, or within the allotted time, the SKIS will exit the ″Customer Learn″ programming mode and the programming will be unsuccessful. The SKIS will also automatically exit the ″Customer Learn″ programming mode if:

- It sees a non-blank Sentry Key when it should see a blank.
- If it has already programmed eight (8) valid Sentry Keys.
- If the ignition switch is turned to the OFF position for more than about fifty (50) seconds.

NOTE: If you attempt to start the vehicle while in “Customer Learn” mode (LED flashing), the vehicle will behave as though an invalid key is being used (i.e. the engine will stall after two (2) seconds of running). No faults will be logged.

NOTE: Once a Sentry Key has been programmed to a particular vehicle, it cannot be used on any other vehicle.

WIPERS/WASHERS

DESCRIPTION

FRONT WINDSHIELD WIPER SYSTEM

The front windshield wiper/washer switch is mounted on the right side of the multi-function switch (Fig. 1), on the steering column, behind the steering wheel.

The wiper system has LOW, HIGH, and INTERMITTENT switch positions. The intermittent wiper system, in addition to low and high speed, has a delay mode and a pulse wipe mode.

The intermittent wiper function is integral to the wiper switch. All electronics and relay are inside the switch assembly. The wiper switch also includes the MIST feature which provides a single wipe when actuated.

FRONT WINDSHIELD WASHER SYSTEM

This vehicle is equipped with an electrically operated windshield washer pump. The washers are operated by a switch in the multi-function switch control lever (Fig. 1). The lever is located on the right side of the steering column.

The electric pump assembly is mounted directly to the reservoir. A permanently lubricated motor is coupled to an impeller type pump. The pump and reservoir are serviced as separate assemblies.

WIPERS/WASHERS (Continued)

5 - CANCELLING CAM
6 - PANEL DIMMER/INTERIOR LIGHT SWITCH
7 - EXTERIOR LIGHTING CONTROL/FOG LAMP

REAR WINDSHIELD WIPER SYSTEM

The driver controls an electrically operated intermittent rear wiper system with the switch located on the instrument panel accessory switch bezel. The rear wiper is controlled by ignition switched battery current through a fuse in the fuse block, and will operate only when the ignition switch is in the Accessory or ON positions.

The intermittent rear wiper system allows the driver to select an intermittent wipe mode. The intermittent wipe mode delay time has a fixed delay interval of about four seconds between sweeps. This system also has a wipe-after-wash feature that operates the rear wiper for as long as the washer pump is energized, then provides about two additional sweeps of the wiper after the washer pump is de-energized.

The rear wiper motor module operates on a separate non-switched battery current feed through a fuse in the fuse block.

The rear wiper system includes the following components:

- Rear wiper and washer switch.
- Rear wiper arm and blade.
- Rear wiper motor module.

REAR WINDSHIELD WASHER SYSTEM

The driver controls all rear washer system functions with the switch integral to the accessory switch bezel in the instrument panel. The rear washer system is controlled by ignition switched battery current through a fuse in the fuse block, and will operate only when the ignition switch is in the ACCESSORY or ON positions.

This system has a wipe-after-wash feature that operates the rear wiper for as long as the washer pump is energized, then provides about two additional sweeps of the wiper after the washer pump is de-energized.

The rear washer system shares the washer reservoir of the front windshield washer system. The front washer pump is a two way pump that is reversed depending on which switch is activated.

The rear washer system includes the following components:

- Washer reservoir and pump.
- Wiper and washer switch.
- Rear washer nozzle and plumbing.

WIPERS/WASHERS (Continued)

OPERATION

FRONT WINDSHIELD WIPER SYSTEM

Move the control lever up to select the desired wiper speed. Move the lever upward to the second detent for Low speed wiper operation, or to the third detent for High speed operation.

Use the intermittent wiper when weather conditions make a single wiping cycle, with a variable pause between cycles, desirable. Move the lever to the DEL position, then select the delay interval by turning the end of the lever. The delay can be regulated from a maximum of approximately 18 ± 0.5 seconds between cycles, to a cycle every second ± 0.5 second.

The windshield wipers will only operate with the ignition switch in the ACCESSORY or IGNITION RUN position. The wiper circuit is protected against over loads by a fuse in the fuse block and a circuit breaker within the wiper motor. This protects the circuitry of the wiper system and the vehicle. The wiper motor has permanent magnet fields.

The intermittent wiper delay mode has a range of 1 ± 0.5 to 18 ± 0.5 seconds. Pulse wipe is accomplished by holding stalk lever in the WASH position momentarily. The wiper blades then sweep once or twice after the WASH at low speed and then return to the previous wiper switch mode.

The wiper system completes the wipe cycle when the switch is turned OFF. The blades park in the lowest portion of the wipe pattern.

Push down on the wiper lever to activate a single wipe to clear off road mist or spray from a passing vehicle. As long as the lever is held down, the wipers will continue to operate.

FRONT WINDSHIELD WASHER SYSTEM

To use the washer, pull the stalk lever toward you and hold while spray is desired. If the stalk lever is pulled while in the delay range, the wiper will operate for two wipe cycles (± 1) after the stalk lever is released, and then resume the intermittent interval previously selected.

The wash function can be accessed in the OFF position of the wiper control switch. Pulling the washer stalk lever rearward when the switch is in the OFF position will operate the wipers and washer motor pump continuously until the stalk lever is released. Releasing the stalk lever will stop the washer pump but the wipers will complete the current wipe cycle followed by an average of two more wipe cycles (± 1) before the wipers park and the module turns off.

If the stalk lever is pulled while in the OFF position, the wipers will operate for two wipe cycles, then turn OFF.

Fluid, gravity fed from the reservoir, is forced by the pump through rubber hoses to the hood mounted nozzles which direct the fluid to the windshield.

REAR WINDSHIELD WIPER SYSTEM

A rocker switch located in the accessory switch bezel, below the radio turns the rear wiper ON or OFF. When this switch is pressed the rear wiper will operate at a fixed interval of about four seconds.

Press and hold the switch as long as spray is desired. If the switch is depressed while the wiper is ON, the wipers will operate for a few seconds after the switch is released then resume the previously set mode of intermittent wiper.

NOTE: The washers will stop spraying if the switch is pressed longer than 30 seconds.

REAR WINDSHIELD WASHER SYSTEM

The vehicle operator selects the rear washer system functions using the wiper and washer switch, which is located on the instrument panel, accessory switch bezel. The instrument panel switch provides a hard wired ignition switched battery current feed to the rear washer pump for the washer system function.

Press and hold the switch as long as spray is desired. If the switch is depressed while the wiper is ON, the wipers will operate for a few seconds after the switch is released then resume the previously set mode of intermittent wiper.

NOTE: The washers will stop spraying if the switch is pressed longer than 30 seconds.

DIAGNOSIS AND TESTING

DIAGNOSIS AND TESTING - FRONT WIPER CONDITIONS

The following is a list of general wiper motor system problems, the tests that are to be performed to locate the faulty part, and the corrective action to be taken.

Whatever the problem, disconnect motor wire harness and clean the terminals, then connect motor wire harness and test.

Refer to Wiring Diagrams for circuit information and connector call-outs.

MOTOR WILL NOT OPERATE ALL SWITCH POSITIONS

(1) Check fuse 1, in the fuse block (Fig. 2).
  (a) If fuse is OK, go to Step 2.

WIPERS/WASHERS (Continued)

(b) If fuse is defective, replace and check motor operation in all switch positions.

(c) If motor is still inoperative and the fuse does not blow, go to Step 2.

(d) If replacement fuse blows, go to Step 6.

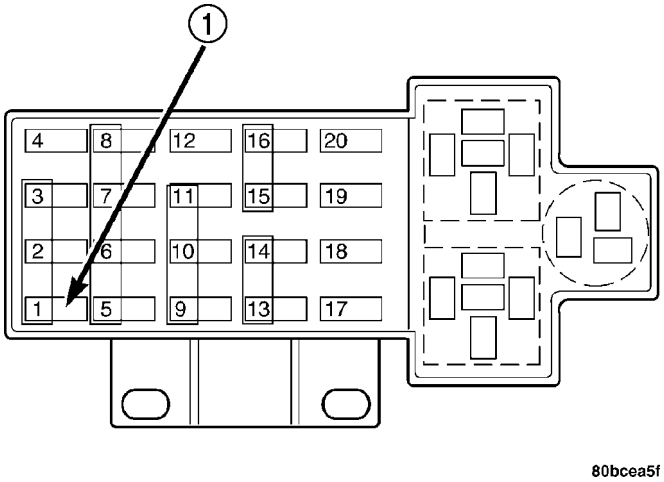

Fig. 2 FUSE BLOCK

1 - FUSE 1 WIPER

(2) Disconnect motor harness connector.

(3) Check motor low speed. Using two jumper wires, connect one jumper wire between the battery positive terminal and terminal 4 of the motor connector. Connect the other jumper wire to the battery negative terminal and terminal 1 of the motor (Fig. 3). Check motor high speed, connect the positive jumper wire to terminal 5 of the motor connector. Connect the negative jumper wire to terminal 1 of the motor.

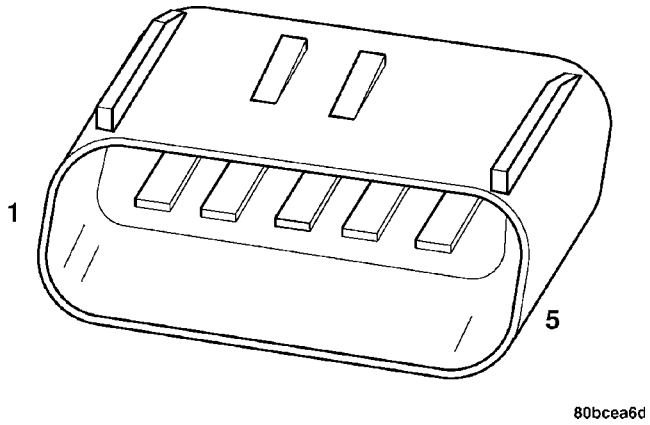

Fig. 3 WINDSHIELD WIPER MOTOR CONNECTOR

(a) If motor does not run in high or low speed go to Step 4.

(b) If motor does run, go to Step 5.

(4) Using an ohmmeter, check for good ground at terminal 1 of the motor. If OK, replace motor. If not repair the ground circuit as necessary.

(5) Check terminal 2 of wiper switch connector for continuity to ground. If OK, go to Step 6. If not OK, repair the ground circuit as necessary.

(6) Using a voltmeter, with wiper switch connected, connect negative lead to terminal 1 of the motor. Connect the positive lead to terminal 4 of the wiper switch connector (Fig. 4).

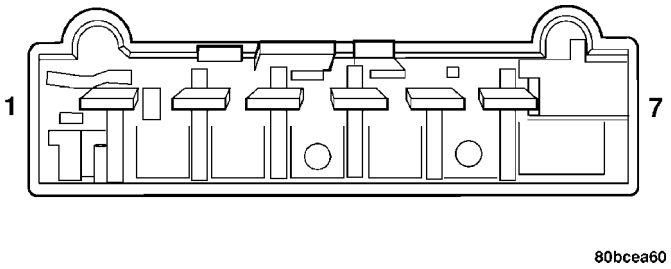

Fig. 4 WIPER/WASHER SWITCH CONNECTOR

(a) If no voltage, repair wiring as necessary. If OK, go to Step b.

(b) Check wiper switch low speed. Connect voltmeter positive lead to terminal 6 of the wiper switch connector. Move wiper stalk to LOW position. If no voltage, replace switch.

(c) Check wiper switch high speed, connect voltmeter positive lead to terminal 5 of the wiper switch connector. Move wiper stalk to HIGH position. If no voltage, replace switch.

(7) Disconnect motor connector and replace fuse 1 in fuse block.

(a) If fuse does not blow, replace motor.

(b) If fuse blows, disconnect wiper switch and replace fuse.

(c) If fuse does not blow, replace switch.

(d) If fuse blows, repair wiring as necessary.

MOTOR OPERATES SLOWLY AT ALL SPEEDS

(1) Remove wiper arms and cowl screen. Disconnect motor linkage from motor. Connect an ammeter between battery positive terminal and terminal 4 of the motor connector. Turn wiper motor on and check ampere reading.

If motor runs and ammeter reading is more than 6 amps, go to Step 2. If less than 6 amps, go to Step 3.

(2) Using an ohmmeter, check the high and low circuits for a short to ground. Refer to Wiring Diagrams.

(3) Check to see if wiper linkage or pivots are binding or caught.

WIPERS RUN AT HIGH SPEED WITH SWITCH IN LOW SPEED POSITION OR WIPERS RUN AT LOW SPEED WITH SWITCH IN HIGH SPEED POSITION.

(1) Check for crossed wires in harness connector from wiper switch to motor.

(2) If OK, replace wiper switch.

WIPERS/WASHERS (Continued)

WIPERS WILL OPERATE CONTINUOUSLY WITH THE SWITCH IN THE INTERMITTENT POSITION - WHEN WIPER SWITCH IS TURNED OFF, WIPERS STOP WHEREVER THEY ARE WITHOUT RETURNING TO PARK POSITION.

(1) Check at terminal 1 of the motor for a good ground.

(2) Turn ignition switch OFF. Disconnect the wiper switch harness connector. Using an ohmmeter with the motor in the park position, check for continuity between terminal 2 of the wiper switch harness connector (Fig. 5) and terminal 1 of the motor. If continuity, replace wiper switch. If no continuity, repair wiring as necessary.

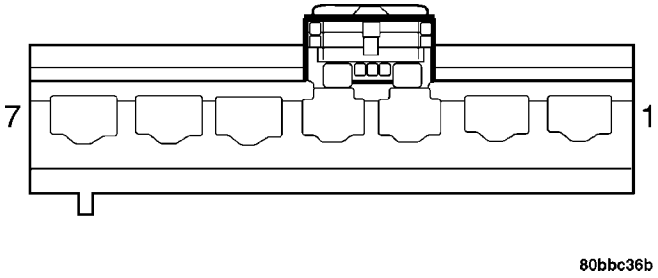

Fig. 5 WINDSHIELD WIPER SWITCH HARNESS CONNECTOR

WIPERS DO NOT OPERATE WHEN WASHER MOTOR IS ENGAGED (PULSE WIPE) OR WIPERS DO OPERATE IN INTERMITTENT POSITION.

Check for a good ground at terminal 1 of the motor and at wiper switch terminal 2. If OK, replace wiper switch. If not OK, repair wiring as necessary.

DIAGNOSIS AND TESTING - REAR WIPER SYSTEM

The rear window wiper system operates in several modes:

- Intermittent wipe.
- Wash
- Wipe after wash.

(1) Check the fused B(+) fuse in the fuse block. If OK, go to Step 2. If not OK, repair the shorted circuit or component as required and replace the faulty fuse.

(2) Check for battery voltage at the fused B(+) fuse in the fuse block. If OK, go to Step 3. If not OK, repair the open fused B(+) circuit to the Power Distribution Center (PDC) fuse as required.

(3) Check the fused ignition switch output (run/accessory) fuse in the fuse block. If OK, go to Step 4. If not OK, repair the shorted circuit or component as required and replace the faulty fuse.

(4) Turn the ignition switch to the On position. Check for battery voltage at the fused ignition switch output (RUN/ACCESSORY) fuse in the fuse block. If OK, turn the ignition switch to the Off position and go to Step 5. If not OK, repair the open fused ignition switch output (RUN/ACCESSORY) circuit to the ignition switch as required.

(5) Disconnect and isolate the battery negative cable. Disconnect the rear windshield wiper/washer switch wire harness connector. Reconnect the battery negative cable. Turn the ignition switch to the ON position. Check for battery voltage at the fused ignition switch output (RUN/ACCESSORY) circuit cavity of the instrument panel wire harness connector for the rear windshield wiper and washer switch. If OK, go to Step 6. If not OK, repair the open fused ignition switch output (RUN/ACCESSORY) circuit to the fuse block fuse as required.

(6) Turn the ignition switch to the OFF position. Disconnect and isolate the battery negative cable.

(7) Remove the liftgate inner trim panel. Disconnect the liftgate wire harness connector from the rear wiper motor. Check for continuity between the ground circuit cavity of the liftgate wire harness connector for the rear wiper motor and a good ground. There should be continuity. If not OK, repair the open ground circuit to ground as required.

(8) Reconnect the battery negative cable. Check for battery voltage at the fused B(+) circuit cavity of the liftgate wire harness connector for the rear wiper motor. If not OK, repair the open fused B(+) circuit to the fuse block fuse as required.

(9) Turn the rear wiper switch to the ON position. Check for battery voltage at the rear wiper motor control circuit cavity of the liftgate wire harness connector. If OK, replace the faulty rear wiper motor. If not OK, repair the open rear wiper motor control circuit to the wiper and washer switch as required.

DIAGNOSIS AND TESTING - WASHER SYSTEM

Whenever a windshield washer malfunction occurs, first verify that the washer pump connector and the multi-function switch, front wiper/washer switch connector is properly connected before starting diagnosis and testing. Also check the rear wiper/washer switch connection. Refer to WASHER SYSTEM TEST table.

WIPERS/WASHERS (Continued)

WASHER SYSTEM TEST

CONDITION	POSSIBLE CAUSES	CORRECTION
PUMP RUNS NO FLUID FLOWING.	1. NO FLUID IN THE RESERVOIR.	1. FILL RESERVOIR.
	2. NOZZLE PLUGGED OR FROZEN.	2. THAW AND CHECK FLOW IF BLOCKED
	3. BROKEN, LOOSE OR PINCHED HOSE.	3. CHECK FLOW THROUGH HOSE CONNECTIONS.
	4. FAULTY PUMP.	4. APPLY BATTERY VOLTAGE TO MOTOR TERMINALS, REPLACE IF PUMP DOES NOT RUN.
SYSTEM OPERATES INTERMITTENTLY.	1. LOOSE WIRE CONNECTION.	1. CHECK WIRE CONNECTIONS.
	2. FAULTY SWITCH.	2. DISCONNECT WIRE HARNESS USE VOLTMETER TO CHECK SWITCH.
SYSTEM OUTPUT IS LOW.	1. PINCHED HOSE.	1. CHECK FLOW THROUGH HOSE CONNECTION.
	2. HOSE BLOCKED.	2. DISCONNECT HOSE AT NOZZLE CHECK FOR FLOW. REPLACE AS NECESSARY.

FRONT WASHER NOZZLE

REMOVAL

(1) Open hood.

(2) Remove the rear underhood silencer pad fasteners.

(3) Disconnect the washer hose from the underside of the front washer nozzle.

(4) Lower hood down.

(5) Using a plastic body filler spreader or equivalent (credit card), gently place it underneath the front of the washer nozzle. Be careful not to damage the hood seal underneath the nozzle.

(6) Rock the nozzle back and forth slightly to release it from the hood panel.

INSTALLATION

(1) Place the nozzle into hood opening and snap into place.

(2) Open hood.

(3) Connect the washer hose to the underside of the washer nozzle.

(4) After connecting hose, check for proper system function and to assure leak free connections by actuating the front washer system switch from inside of vehicle.

(5) Install the underhood, rear hood silencer pad fasteners.

(6) Close hood.

(7) Verify system operation.

FRONT WIPER ARMS

REMOVAL

(1) Place the wiper arm/blades in the PARK position and turn ignition OFF.

(2) Open hood.

(3) Using a trim stick (special tool #C-4755) or equivalent, gently pry up on the wiper arm nut cap and remove (Fig. 6).

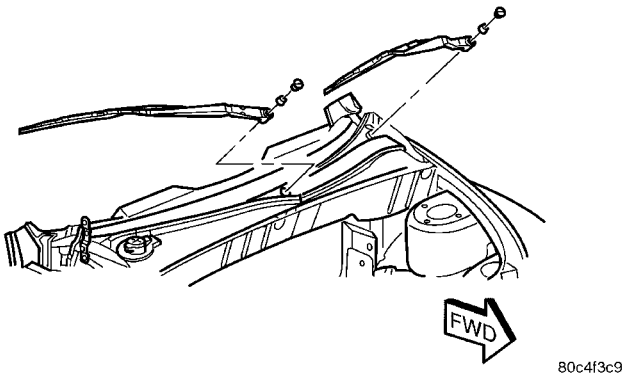

Fig. 6 FRONT WIPER ARM - REMOVE/INSTALL

(4) Remove wiper arm retaining nut (Fig. 6).

(5) Remove the arm from the pivot using a rocking motion while the arm is in an over/centered position (Fig. 6).

(6) Clean metal splinters OFF the pivot shafts.

FRONT WIPER ARMS (Continued)

INSTALLATION

Before installation activate wiper system to ensure the wiper module is in the PARK position. Position wiper arms so that the tip of the driver's blade and the middle of the passenger's blade is on the park line on the windshield. Refer to Adjustments in this section for Wiper Arm Adjustment.

(1) Place the arm on the pivot while the arm is in an over/centered position (Fig. 6).

(2) Install the wiper arm retaining nut (Fig. 6)and torque to 21 N·m (190 in. lbs.).

(3) Install the wiper arm nut cap (Fig. 6).

(4) Close hood.

(5) Verify system operation.

ADJUSTMENTS

ADJUSTMENT - FRONT WIPER ARMS

(1) Open hood.

(2) Using a trim stick (special tool #C-4755) or equivalent, gently pry up on the wiper arm nut cap and remove (Fig. 6).

(3) Remove wiper arm retaining nut (Fig. 6).

(4) Remove the arm from the pivot using a rocking motion while the arm is in an over/centered position (Fig. 6).

(5) The wiper blade should be within the tolerance shown by the tick mark. The park line or tick mark, is on the windshield (Fig. 7).

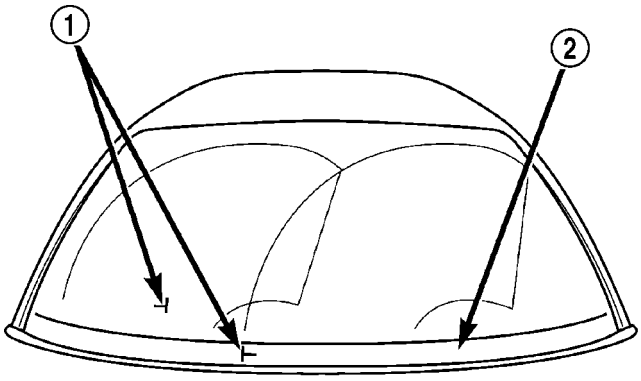

Fig. 7 WIPER BLADE/ARM PARK LINES

1 - PARK LINES
2 - BLACK OUT AREA

NOTE: In the event that the wiper blade tip excessively strikes the cowl screen due to long term normal wear, reposition the wiper blade tip slightly above the park line. Make sure that the wipers are in the PARK position.

(6) Place the arm on the pivot while the arm is in an over/centered position (Fig. 6).

(7) Install the wiper arm retaining nut (Fig. 6)and torque to 21 N·m (190 in. lbs.).

(8) Install the wiper arm nut cap (Fig. 6).

(9) Close hood.

(10) Verify system operation.

ADJUSTMENT - FRONT WIPER ARMS - RHD

(1) Open hood.

(2) Using a trim stick (special tool #C-4755) or equivalent, gently pry up on the wiper arm nut cap and remove (Fig. 6).

(3) Remove wiper arm retaining nut (Fig. 6).

(4) Remove the arm from the pivot using a rocking motion while the arm is in an over/centered position (Fig. 6).

(5) The wiper blade should be parked within the tolerance shown by the tick mark. The park line, or tick mark, is on the windshield (Fig. 8).

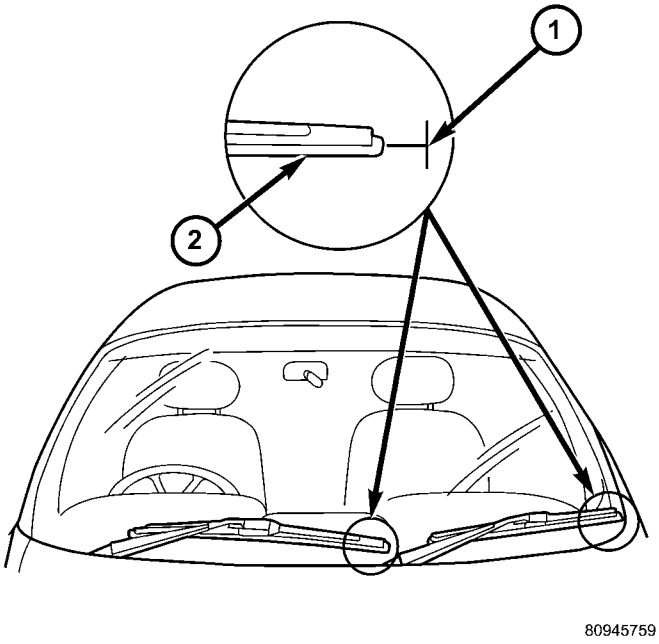

Fig. 8 WIPER BLADE/ARM PARK LINES - RHD

1 - ALIGNMENT TOLERANCE ON WINDSHIELD
2 - WIPER BLADE

NOTE: In the event that the wiper blade tip excessively strikes the cowl screen due to long term normal wear, reposition the wiper blade heel slightly above the park line. Make sure that the wipers are in the PARK position.

(6) Place the arm on the pivot while the arm is in an over/centered position (Fig. 6).

(7) Install the wiper arm retaining nut (Fig. 6) and torque to 21 N·m (190 in. lbs.).

FRONT WIPER ARMS (Continued)

(8) Install the wiper arm nut cap (Fig. 6).
(9) Close hood.
(10) Verify vehicle and system operation.

FRONT WIPER BLADES

REMOVAL

(1) Lift wiper arm to the over center position.
(2) Remove blade assembly from arm by pushing release tab under arm tip and slide blade away from arm tip (Fig. 9).

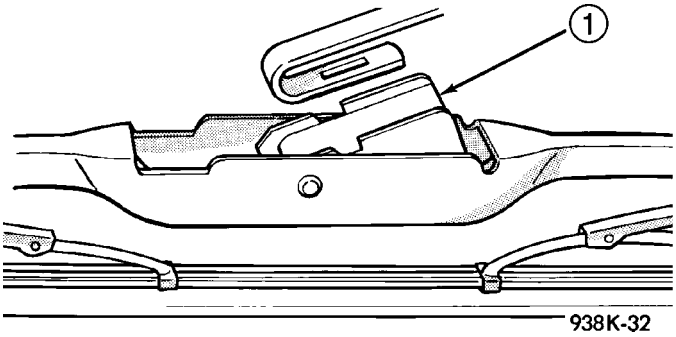

Fig. 9 FRONT WIPER BLADE - REMOVE/INSTALL

1 - RELEASE TAB

(3) Gently place wiper arm tip on glass surface.

CLEANING - FRONT WIPER BLADES

Wiper blades exposed to the weather for a long period of time tend to lose their wiping effectiveness. Periodic cleaning of the wiper blade is recommended to remove the accumulation of salt and road grime. The wiper blades, arms and windshield should be cleaned with a sponge or cloth and a mild detergent or nonabrasive cleaner. If the wiper blades continue to streak or smear, they should be replaced. The wiper blade should run smoothly across the windshield in both directions. The wiper blade should slightly roll over center when the blade reverses direction. A wiper blade insert that has lost flexibility or a wiper arm that has lost spring tension, will cause the blade to skip or chatter across the windshield. If the wiper blades are new and the wiper arm spring tension is OK and a chattering sound is emitted from the wiper(s), the wiper blade is not rolling over center. If this condition exists (Refer to 8 - ELECTRICAL/WIPERS/WASHERS/WIPER ARMS - ADJUSTMENTS).

INSTALLATION

(1) Install blade assembly on arm by sliding the blade into the arm tip until it clicks (Fig. 9).
(2) Let wiper arm/blade rest on front windshield.
(3) Verify system operation.

FRONT WIPER BLADE ELEMENTS

REMOVAL

(1) Lift wiper arm to raise blade off glass.
(2) Remove blade assembly from arm by pushing release tab under arm tip and slide blade away from arm tip (Fig. 9).
(3) Let wiper arm rest on front windshield.
(4) Remove wiping element from blade assembly. Pull pocket of the rubber element out of the end of the claw together with vertebra (metal rails) (Fig. 10).

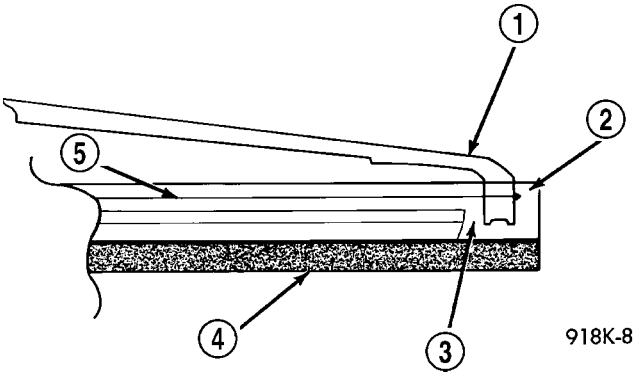

Fig. 10 WIPER BLADE ELEMENT - TYPICAL

1 - CLAW
2 - TO GRASP AND PULL
3 - CHANNEL
4 - RUBBER ELEMENT
5 - VERTABRA

INSTALLATION

After Installation, check that the element and vertebra are through all claws and the final claw is locked in the pocket.
(1) Install wiping element into blade assembly. Push pocket of the rubber element in the end claw together with vertebra (metal rails) (Fig. 10).
(2) Install blade assembly on arm by pushing tab under the hook on the arm tip and slide blade into arm tip (Fig. 9).
(3) Let wiper arm/blade rest on front windshield.
(4) Verify system operation.

FRONT WIPER MODULE

REMOVAL

(1) Open hood.
(2) Disconnect and isolate the battery negative cable (Fig. 11).
(3) Using a trim stick (special tool #C-4755) or equivalent, gently pry up on the wiper arm nut cap and remove (Fig. 6).

FRONT WIPER MODULE (Continued)

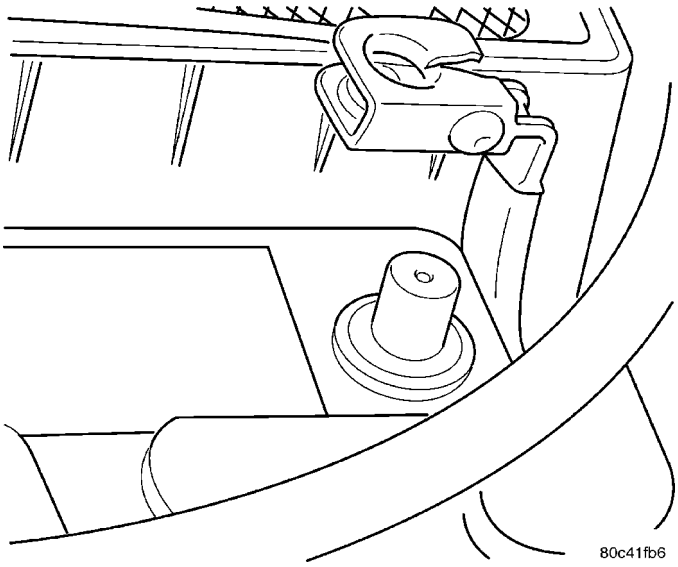

Fig. 11 BATTERY NEGATIVE CABLE - REMOVE/ INSTALL

(4) Remove wiper arm retaining nut (Fig. 6).

(5) Remove the arm from the pivot using a rocking motion while the arm is in an over/centered position (Fig. 6).

(6) Remove the cowl cover. The right side cover overlaps the left side cover, so they both must be removed.

(a) Remove the rear engine compartment seal at the cowl.

(b) Remove the four push retainers to the right side cowl cover and remove from vehicle.

(c) Remove the three push retainers to the left side cowl cover and remove from vehicle.

(7) Disconnect front wiper motor posi-lock harness connector.

(8) Remove three front wiper module mounting bolts and remove module from vehicle (Fig. 12).

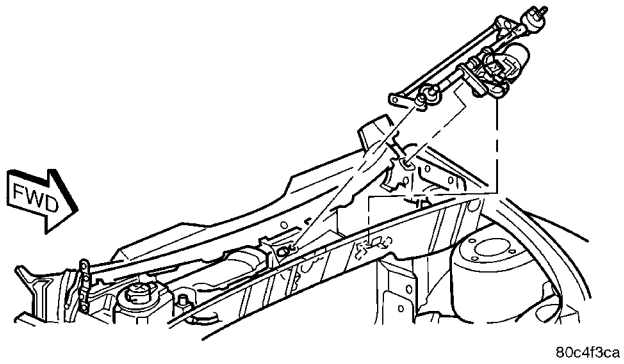

Fig. 12 FRONT WIPER MODULE - REMOVE/INSTALL

NOTE: If replacing the front wiper linkage, the wiper motor must be transferred to the new linkage.

- **Disconnect drive link from motor crank ball joint.**
- **Remove three bolts to the front wiper motor and separate from linkage.**

INSTALLATION

NOTE: If the front wiper linkage was replaced, install the wiper motor on the new linkage.

- **Place the motor on the front wiper module and install the three bolts to the front windshield wiper motor.**
- **Reconnect drive link to motor crank ball joint.**

(1) Place the front wiper module into cowl area and install the three mounting bolts (Fig. 12). Torque the mounting screws to 8 N·m (75 in. lbs.).

(2) Connect the front wiper motor posi-lock harness connector.

(3) Install the cowl cover. The right side cover overlaps the left side cover.

(a) Place the left side cowl cover into position and install the three push retainers.

(b) Place the right side cowl cover into position and install the four push retainers.

(c) Install the rear engine compartment seal at the cowl.

Before installation of the front wiper arms, activate the wiper system to ensure the front wiper module is in the PARK position. Position wiper arms so that the tip of the driver's blade and the middle of the passenger's blade is on the park line on the windshield (Refer to 8 - ELECTRICAL/WIPERS/WASHERS/WIPER ARMS - ADJUSTMENTS).

(4) Place the arm on the pivot while the arm is in an over/centered position (Fig. 6).

(5) Install the wiper arm retaining nut (Fig. 6) and torque to 21 N·m (190 in. lbs.).

(6) Install the wiper arm nut cap (Fig. 6).

(7) Connect the battery negative cable (Fig. 11).

(8) Close hood.

(9) Verify vehicle and system operation.

FRONT WIPER MOTOR

DIAGNOSIS AND TESTING - WIPER MOTOR

Whenever a wiper motor malfunction occurs, verify that the wire harness is properly connected, then start normal diagnosis and repair procedures. Refer to the WIPER MOTOR DIAGNOSIS table.

FRONT WIPER MOTOR (Continued)

WIPER MOTOR DIAGNOSIS

CONDITION	POSSIBLE CAUSES	CORRECTION
WIPER BLADES DO NOT PARK PROPERLY.	(1) WIPER ARMS IMPROPERLY PARKED.	(1) REMOVE WIPER ARMS AND REPARK. REFER TO ELECTRICAL, WIPERS/WASHERS, WIPER ARM, REMOVAL.
	(2) WIPER ARMS ARE LOOSE ON PIVOT SHAFT.	(2) REMOVE WIPER ARM AND REPARK. REFER TO ELECTRICAL, WIPERS/WASHERS, WIPER ARM, REMOVAL.
	(3) MOTOR CRANK LOOSE AT OUTPUT SHAFT.	(3) REMOVE WIPER ARM, RUN WIPER MOTOR TO PARK POSITION AND REMOVE THE MODULE. WITHOUT ROTATING THE MOTOR OUTPUT SHAFT, REMOVE THE CRANK AND CLEAN ANY FOREIGN MATTER FROM THE MOTOR SHAFT. INSTALL THE MOTOR CRANK IN ITS ORIGINAL POSITION.
MOTOR STOPS IN ANY POSITION WHEN THE SWITCH IS TURNED OFF.	(1) OPEN PARK CIRCUIT.	(1) CHECK PARK SWITCH BY DISCONNECTING THE WIRE CONNECTOR. PLACE A JUMPER WIRE FROM PIN 2 TO PIN 4. APPLY BATTERY VOLTAGE TO PIN 3 AND THEN TO PIN 1. REPLACE MOTOR IF IT DOES NOT PARK.
MOTOR WILL NOT STOP WHEN THE SWITCH IS TURNED OFF.	(1) FAULTY SWITCH.	(1) CHECK SWITCH IN LOW, HIGH AND INTERMITTENT POSITION.
WIPER BLADES SLAP AGAINST COWL SCREEN OR WINDOW MOLDINGS.	(1) WIPER ARMS ARE PARKED INCORRECTLY.	(1) PARK WIPER ARMS. REFER TO WIPER ARM ADJUSTMENT.
BLADES CHATTER.	(1) FOREIGN SUBSTANCE SUCH AS POLISH ON GLASS OR BLADES.	(1) CLEAN GLASS AND BLADE ELEMENT WITH NON-ABRASIVE CLEANER.
	(2) ARMS TWISTED, BLADE AT WRONG ANGLE ON GLASS.	(2) REPLACE ARM.
	(3) BLADE STRUCTURE BENT.	(3) REPLACE BLADE.
	(4) BLADE ELEMENT HAS PERMANENT SET.	(4) REPLACE BLADE ELEMENT.
WIPER KNOCK AT REVERSAL.	(1) LINKAGE BUSHINGS WORN.	(1) REPLACE WORN LINK. REFER TO ELECTRICAL, WIPERS/WASHERS, WIPER LINKAGE, REMOVAL.
	(2) ARMATURE ENDPLAY IN MOTOR.	(2) REPLACE WIPER MOTOR. REFER TO ELECTRICAL, WIPERS/WASHERS, WIPER MOTOR REMOVAL.

FRONT WIPER MOTOR (Continued)

CONDITION	POSSIBLE CAUSES	CORRECTION
WIPER MOTOR WILL NOT RUN.	(1) BLOWN FUSE.	(1) REPLACE FUSE, AND RUN SYSTEM.
	(2) NEW FUSE BLOWS.	(2) CHECK FOR SHORT IN WIRING OR SWITCH.
	(3) NEW FUSE BLOWS.	(3) REPLACE FUSE, REMOVE MOTOR CONNECTOR, TURN SWITCH ON, FUSE DOES NOT BLOW, REPLACE MOTOR.
	(4) NO VOLTAGE AT MOTOR.	(4) CHECK SWITCH AND WIRING HARNESS. REFER TO WIRING DIAGRAMS.
	(5) POOR GROUND.	(5) REPAIR GROUND WIRE CONNECTION AS NECESSARY.

REMOVAL

To service the front wiper motor, the front wiper module must first be removed.

(1) Open hood.

(2) Disconnect and isolate the battery negative cable (Fig. 11).

(3) Using a trim stick (special tool #C-4755) or equivalent, gently pry up on the wiper arm nut cap and remove (Fig. 6).

(4) Remove wiper arm retaining nut (Fig. 6).

(5) Remove the arm from the pivot using a rocking motion while the arm is in an over/centered position (Fig. 6).

(6) Remove the cowl cover. The right side cover overlaps the left side cover, so they both must be removed.

(a) Remove the rear engine compartment seal at the cowl.

(b) Remove the four push retainers to the right side cowl cover and remove from vehicle.

(c) Remove the three push retainers to the left side cowl cover and remove from vehicle.

(7) Disconnect front wiper motor posi-lock harness connector.

(8) Remove three front wiper module mounting bolts and remove module from vehicle (Fig. 12).

(9) Disconnect drive link to motor crank ball joint.

(10) Remove three bolts to the front wiper motor and separate from module.

INSTALLATION

(1) Place the motor on the wiper linkage and install the three bolts to the front wiper motor.

(2) Reconnect the drive link to the motor crank ball joint.

(3) Place the front wiper module into cowl area and install the three mounting bolts (Fig. 12). Torque the mounting screws to 8 N·m (75 in. lbs.).

(4) Connect the front wiper motor posi-lock harness connector.

(5) Install the cowl cover. The right side cover overlaps the left side cover.

(a) Place the left side cowl cover into position and install the three push retainers.

(b) Place the right side cowl cover into position and install the four push retainers.

(c) Install the rear engine compartment seal at the cowl.

Before installation of the front wiper arms, activate the wiper system to ensure the front wiper module is in the PARK position. Position wiper arms so that the tip of the driver's blade and the middle of the passenger's blade is on the park line on the windshield (Refer to 8 - ELECTRICAL/WIPERS/WASHERS/WIPER ARMS - ADJUSTMENTS).

(6) Place the arm on the pivot while the arm is in an over/centered position (Fig. 6).

(7) Install the wiper arm retaining nut (Fig. 6) and torque to 21 N·m (190 in. lbs.).

(8) Install the wiper arm nut cap (Fig. 6).

(9) Connect the battery negative cable (Fig. 11).

(10) Close hood.

(11) Verify vehicle and system operation.

FRONT WIPER SWITCH

DIAGNOSIS AND TESTING - FRONT WIPER/WASHER SWITCH

Refer to FRONT WIPER/WASHER SWITCH CONTINUITY TEST table and (Fig. 13).

FRONT WIPER/WASHER SWITCH CONTINUITY TEST

MODE	CONTINUITY BETWEEN
OFF	PIN C-1 AND C-6
LOW/MIST	PIN C-4 AND C-6
HIGH	PIN C-4 AND C-5
WASH	PIN C-4 AND C-3
INTERMITTENT	CANNOT BE CHECKED

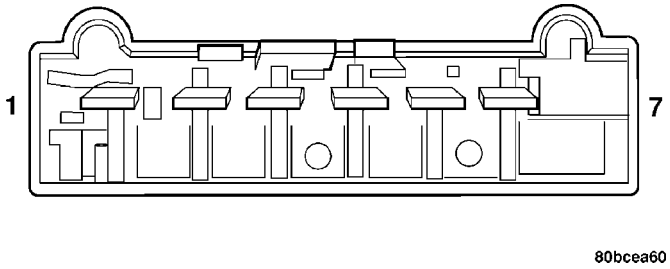

Fig. 13 WIPER/WASHER SWITCH CONNECTOR (C)

REMOVAL

To service the front wiper/washer switch, the multi-function switch must first be removed.

(1) Open hood.

(2) Disconnect and isolate the battery negative cable (Fig. 11).

(3) Remove both upper and lower steering column shrouds (Refer to 19 - STEERING/COLUMN/UPPER SHROUD - REMOVAL).

(4) Disconnect both posi-lock harness connectors at the rear of the multi-function switch (Fig. 14)

(5) Remove multi-function switch mounting screws (Fig. 14)and remove switch from vehicle.

(6) Remove the two torx screws retaining the wiper/washer switch to the multi-function switch and separate (Fig. 15).

INSTALLATION

To service the front wiper/washer switch, the multi-function switch must first be removed.

(1) Place new wiper/washer switch next to the multi-function switch and install two screws (Fig. 15).

(2) Place the multi-function switch into place and install the two mounting screws (Fig. 14). Torque multi-function switch to column retaining screws to 3 N·m (27 in. lbs.).

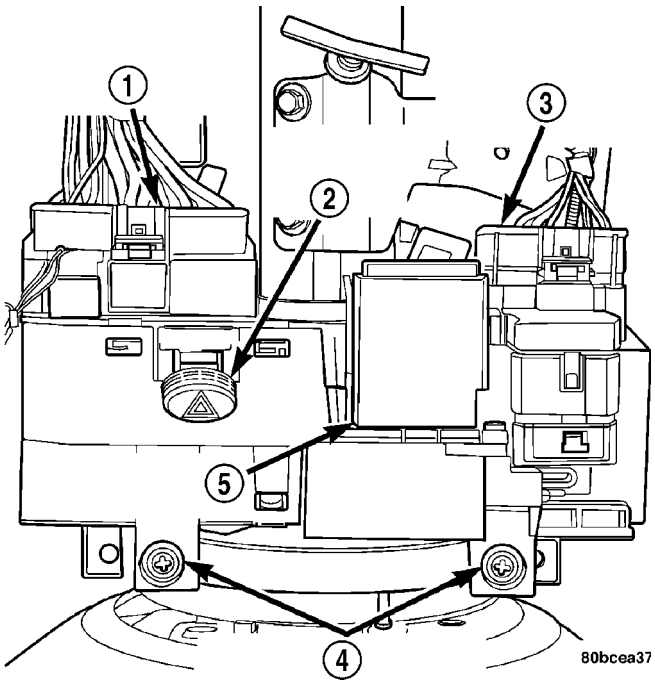

Fig. 14 MULTI-FUNCTION SWITCH - REMOVE/ INSTALL

1 - MULTI-FUNCTION SWITCH CONNECTOR
2 - HAZARD/WARNING SWITCH
3 - WINDSHIELD WIPER/WASHER SWITCH CONNECTOR
4 - MOUNTING SCREWS
5 - COMBINATION FLASHER

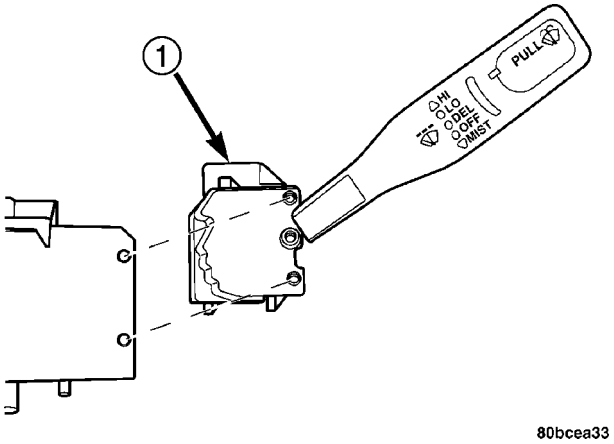

Fig. 15 FRONT WIPER SWITCH - REMOVE/INSTALL

1 - FRONT WIPER SWITCH

(3) Connect both posi-lock harness connectors at the rear of the multi-function switch and front wiper/ washer switch (Fig. 14).

(4) Install both upper and lower steering column shrouds (Refer to 19 - STEERING/COLUMN/UPPER SHROUD - INSTALLATION).

(5) Connect the battery negative cable (Fig. 11).

(6) Close hood.

(7) Verify vehicle and system operation.

REAR WASHER NOZZLE

REMOVAL

(1) Open liftgate.
(2) Remove liftgate CHMSL access panel (Refer to 23 - BODY/DECKLID/HATCH/LIFTGATE/TAILGATE/CHMSL COVER PANEL - REMOVAL).
(3) Disconnect the rear washer hose at nozzle.
(4) Remove the nut retaining the rear washer nozzle and remove the nozzle from rear window glass and vehicle.

INSTALLATION

(1) Install the nozzle into rear window opening and retaining nut to the rear washer nozzle and torque to 2.8 N·m (25 in. lbs.).

NOTE: Verify that the nozzle is pointing straight down.

(2) Connect the rear washer hose at nozzle.
(3) Install liftgate CHMSL access panel (Refer to 23 - BODY/DECKLID/HATCH/LIFTGATE/TAILGATE/CHMSL COVER PANEL - INSTALLATION).
(4) Close liftgate.
(5) Verify vehicle and system operation.

REAR WIPER ARMS

REMOVAL

(1) Remove the rear wiper arm nut cap.
(2) Remove wiper arm retaining nut.
(3) Use a battery terminal puller to remove the wiper arm from the wiper pivot (Fig. 16).

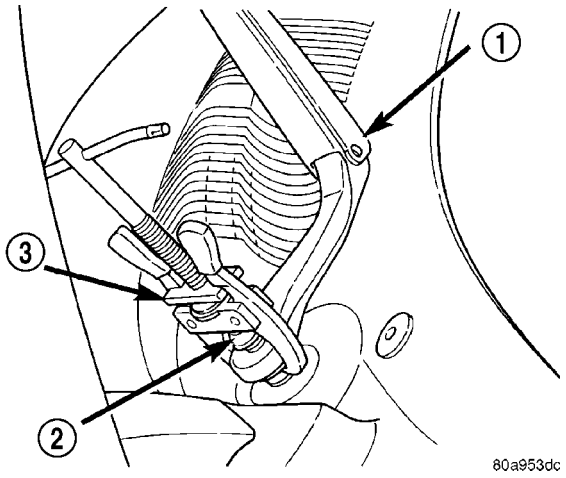

Fig. 16 WIPER ARM PULLER (SHOWN ON FRONT WIPER ARM)

1 - WIPER ARM
2 - WIPER PIVOT
3 - BATTERY TERMINAL PULLER

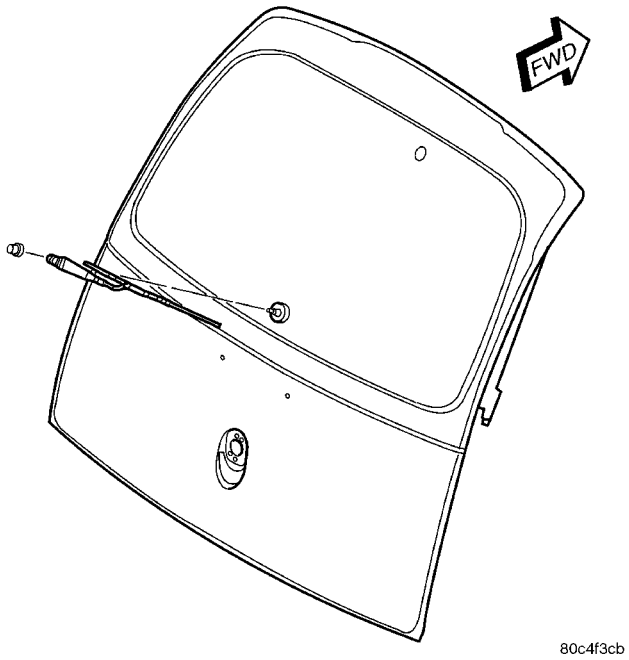

Fig. 17 REAR WIPER ARM - REMOVE/INSTALL

INSTALLATION

Before installation activate wiper system to ensure the wiper module is in the PARK position. Position wiper arm so that the tip of the blade is on the park line on the windshield.

NOTE: Blade should be parked along bottom rear window defogger grid line. Vertical tick mark shows park tolerance.

(1) Install the arm on the pivot (Fig. 17) and position to tick mark (Fig. 18).
(2) Install wiper arm retaining nut and torque to 18-20 N·m (160-175 in. lbs.).
(3) Install the rear wiper arm nut cap.
(4) Verify system operation.

REAR WIPER BLADE

REMOVAL

(1) Lift wiper arm from the glass.
(2) Remove blade assembly from arm by pushing release tab under arm tip and slide blade towards pivot (Fig. 19).
(3) Gently place wiper arm tip on glass surface.

REAR WIPER BLADE (Continued)

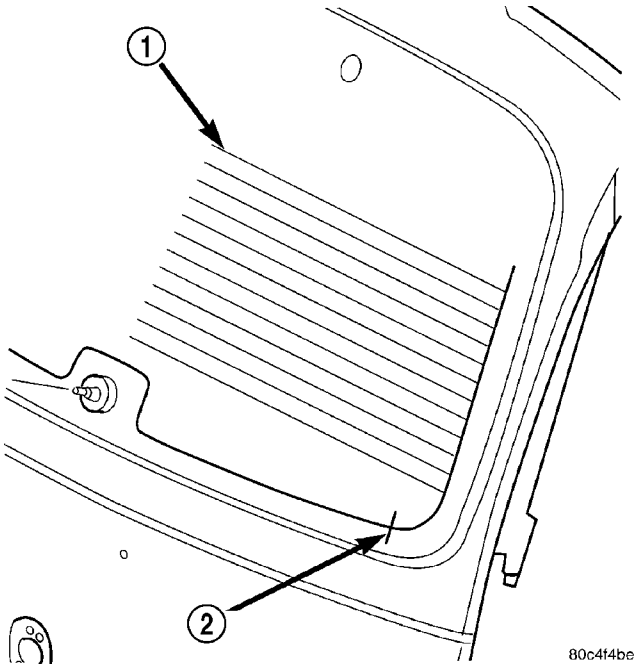

Fig. 18 REAR WIPER BLADE/ARM TICK MARK

1 - EBL GRID LINES
2 - TICK MARK

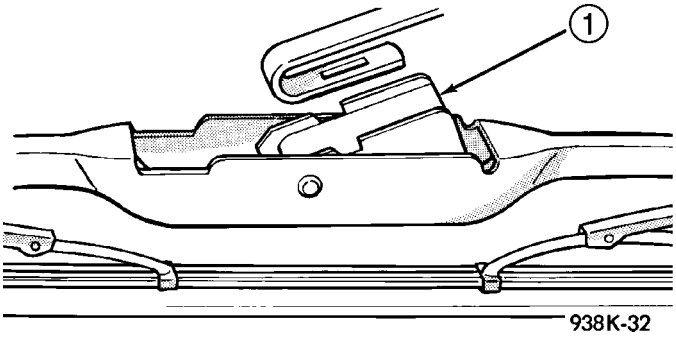

Fig. 19 REAR WIPER BLADE - REMOVE/INSTALL

1 - RELEASE TAB

INSTALLATION

(1) Install blade assembly on arm by sliding blade until it clicks into arm tip (Fig. 19).
(2) Let wiper arm/blade rest on glass.
(3) Verify system operation.

REAR WIPER MOTOR

REMOVAL

(1) Open hood.
(2) Disconnect and isolate the battery negative cable (Fig. 11).
(3) Remove the rear wiper arm nut cap.
(4) Remove wiper arm retaining nut.
(5) Use a battery terminal puller to remove the wiper arm from the wiper pivot (Fig. 16).
(6) Remove liftgate trim panel (Refer to 23 - BODY/DECKLID/HATCH/LIFTGATE/TAILGATE/ TRIM PANEL - REMOVAL).
(7) Disconnect harness connector.
(8) Remove three machine screws to the rear wiper motor and remove from vehicle.

CAUTION: Use extreme care when taking out motor. Damage to the grommet and or window can occur.

INSTALLATION

Before installation activate wiper system to ensure the wiper module is in the PARK position. Position wiper arm so that the tip of the blade is on the park line on the glass.

NOTE: When servicing the rear wiper motor, replace all three rubber well-nuts.

(1) Install three bolts to the rear wiper motor. Torque screws to 6.8 N·m (60 in. lbs.).
(2) Connect harness connector.
(3) Install liftgate trim panel (Refer to 23 - BODY/ DECKLID/HATCH/LIFTGATE/TAILGATE/TRIM PANEL - INSTALLATION).
(4) Install the arm on the pivot (Fig. 17).
(5) Install wiper arm retaining nut and torque to 18-20 N·m (160-175 in. lbs.).
(6) Install the rear wiper arm nut cap.
(7) Connect the battery negative cable (Fig. 11).
(8) Close hood.
(9) Verify vehicle and system operation.

REAR WIPER SWITCH

DIAGNOSIS AND TESTING - REAR WIPER SWITCH

The rear windshield wiper/washer switch may be tested in the vehicle or out of the vehicle, on the bench.

IN-VEHICLE TESTING

(1) Remove the switch from the instrument panel but leave the switch connected, refer to Instrument Panel Systems, Accessory Switch Bezel Removal and Installation.
(2) Turn the ignition switch ON.
(3) Using a voltmeter, check for battery voltage at Pin 1 and 2 (Fig. 20).
(a) If OK, go to Step 4.
(b) If NOT OK, check wiper fuse in the fuse block and the 40 Amp cartridge fuse in the Power

REAR WIPER SWITCH (Continued)

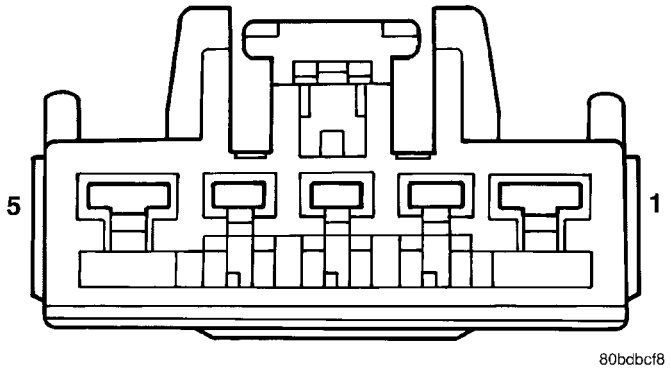

Fig. 20 REAR WIPER SWITCH HARNESS CONNECTOR

Distribution Center (PDC). If fuses are OK, check wiring circuit. Refer to Wiring Diagrams.

(4) Check Pin 5, with switch in the ON position there should be battery voltage and no voltage in the OFF position.

(a) If NOT OK, no voltage in the ON position or voltage in the OFF position. Replace the switch.

BENCH TESTING

(1) First remove switch. Refer to Instrument Panel Systems, Accessory Switch Bezel Removal and Installation.

(2) With switch removed from vehicle, use a jumper wire and connect a 12 volt supply to Pin 1 and 2. Using a third jumper wire, ground Pin 3. Refer to (Fig. 21).

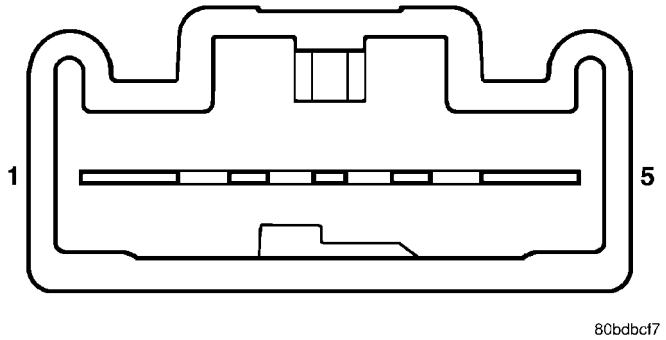

Fig. 21 REAR WIPER SWITCH CONNECTOR

(3) Follow the same procedures used for IN-VEHICLE TESTING, except for step Step 2.

REMOVAL

The Rear Wiper Switch is located within the accessory switch bezel in the lower center stack of the instrument panel. For Removal and Installation of the Rear Wiper Switch, (Refer to 23 - BODY/INSTRUMENT PANEL/ACCESSORY SWITCH BEZEL - REMOVAL) and (Refer to 23 - BODY/INSTRUMENT PANEL/ACCESSORY SWITCH BEZEL - INSTALLATION).

WASHER HOSES

REMOVAL

For damaged or plugged windshield washer hose, remove the affected piece of hose and replace with bulk hose. It may be necessary to de-trim parts of the interior to locate the problem portion of hose. Refer to (Fig. 22) hose routing. Refer also to Body, Interior component Removal and Installation.

INSTALLATION

Depending on how much of the vehicle has been de-trimmed, either splice in a small piece of hose or replace the entire length of affected hose. Verify vehicle and system operation upon reassembly.

WASHER PUMP MOTOR

REMOVAL

(1) Open hood.

(2) Disconnect and isolate the battery negative cable (Fig. 11).

(3) Using a trim stick (special tool #C-4755) or equivalent, gently pry up on the wiper arm nut cap and remove (Fig. 6).

(4) Remove wiper arm retaining nut (Fig. 6).

(5) Remove the arm from the pivot using a rocking motion while the arm is in an over/centered position (Fig. 6).

(6) Remove the right cowl cover.

(a) Remove the rear engine compartment seal at the cowl.

(b) Remove the four push retainers to the right side cowl cover and remove from vehicle.

(7) Remove three reservoir retaining screws.

(8) Disconnect the pump wire connector.

(9) Disconnect the washer hose connections.

(10) Lift washer reservoir out of cowl area and drain into bucket.

(11) Remove plastic strap from around pump.

(12) Gently pry pump away from reservoir and out of grommet. Care must be taken not to puncture reservoir.

(13) Remover rubber grommet from reservoir.

WASHER PUMP MOTOR (Continued)

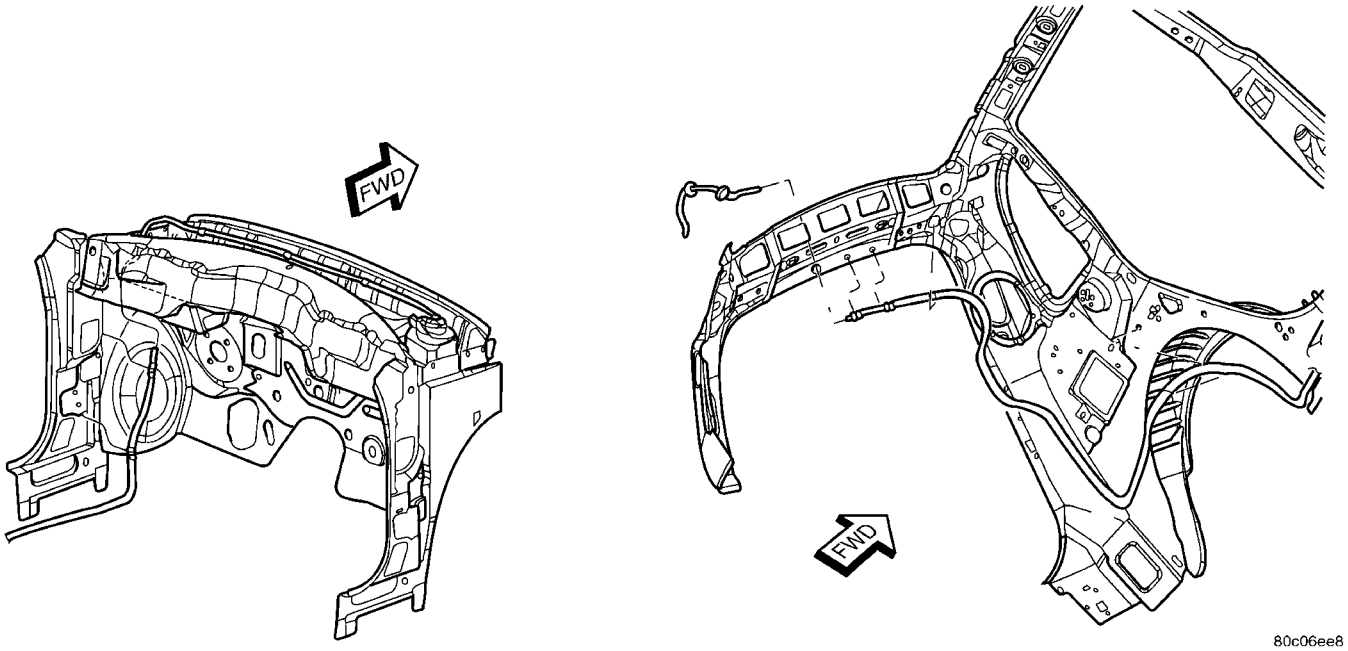

Fig. 22 BODY HOSE ROUTING

INSTALLATION

CAUTION: A new grommet must be used every time the pump is removed/installed from the reservoir to prevent possible leaks in the future.

(1) Install new grommet into the reservoir.
(2) Insert pump into pump grommet.
(3) Place plastic strap over pump assembly and firmly snap into the reservoir.
(4) Place reservoir into cowl area and connect the washer hoses.

NOTE: The hose with the white stripe goes on the white side of the pump and the black hose on the black side of the pump.

(5) Connect the pump wire connector.
(6) Install the three reservoir retaining screws. Torque screws to 8 N·m (70 in. lbs.).
(7) Install the right cowl cover.
(a) Place the right side cowl cover into position and install the four push retainers.
(b) Install the rear engine compartment seal at the cowl.

Before installation of the front wiper arms, activate the wiper system to ensure the front wiper module is in the PARK position. Position wiper arms so that the tip of the driver's blade and the middle of the passenger's blade is on the park line on the windshield (Refer to 8 - ELECTRICAL/WIPERS/WASHERS/WIPER ARMS - ADJUSTMENTS).

(8) Place the arm on the pivot while the arm is in an over/centered position (Fig. 6).
(9) Install the wiper arm retaining nut (Fig. 6) and torque to 21 N·m (190 in. lbs.).
(10) Install the wiper arm nut cap (Fig. 6).
(11) Connect the battery negative cable (Fig. 11).
(12) Close hood.
(13) Verify vehicle and system operation.

WASHER RESERVOIR

REMOVAL

(1) Open hood.
(2) Disconnect and isolate the battery negative cable (Fig. 11).
(3) Using a trim stick (special tool #C-4755) or equivalent, gently pry up on the wiper arm nut cap and remove (Fig. 6).
(4) Remove wiper arm retaining nut (Fig. 6).
(5) Remove the arm from the pivot using a rocking motion while the arm is in an over/centered position (Fig. 6).
(6) Remove the right cowl cover. The right side cover overlaps the left side cover.
(a) Remove the rear engine compartment seal at the cowl.
(b) Remove the four push retainers to the right side cowl cover and remove from vehicle.
(7) Remove three reservoir retaining screws.
(8) Disconnect the pump wire connector.
(9) Disconnect the washer hose connections.

WASHER RESERVOIR (Continued)

(10) Lift washer reservoir out of cowl area and drain into bucket.

NOTE: If replacing the washer reservoir, the washer pump must be transferred to the new reservoir. The new reservoir will come with a new washer pump grommet.

(11) Remove plastic strap from around pump.

(12) Gently pry pump away from reservoir and out of grommet.

INSTALLATION

(1) Insert pump into pump grommet.

(2) Place plastic strap over pump assembly and snap firmly into the reservoir.

(3) Place reservoir into cowl area and connect the washer hoses.

NOTE: The hose with the white stripe goes on the white side of the pump and the black hose on the black side of the pump.

(4) Connect the pump wire connector.

(5) Install the three reservoir retaining screws. Torque screws to 8 N·m (70 in. lbs.).

(6) Install the cowl cover. The right side cover overlaps the left side cover.

(a) Place the right side cowl cover into position and install the four push retainers.

(b) Install the rear engine compartment seal at the cowl.

Before installation of the front wiper arms, activate the wiper system to ensure the front wiper module is in the PARK position. Position wiper arms so that the tip of the driver's blade and the middle of the passenger's blade is on the park line on the windshield (Refer to 8 - ELECTRICAL/WIPERS/WASHERS/WIPER ARMS - ADJUSTMENTS).

(7) Place the arm on the pivot while the arm is in an over/centered position (Fig. 6).

(8) Install the wiper arm retaining nut (Fig. 6) and torque to 21 N·m (190 in. lbs.).

(9) Install the wiper arm nut cap (Fig. 6).

(10) Connect the battery negative cable (Fig. 11).

(11) Close hood.

(12) Verify vehicle and system operation.

NAVIGATION/ TELECOMMUNICATION

DESCRIPTION

TELECOMMUNICATION

The hands-free cellular system on this vehicle uses Bluetooth™ technology to provide wireless communication between the operator's compatible cellular telephone and the vehicle's on-board receiver.

The system uses voice recognition technology to control operation. The incoming voice is broadcast through the vehicle's radio speakers, automatically overriding any other audio signals on the front speakers when the hands-free system is in use. A microphone in the rearview mirror picks up vehicle occupant's voices.

The system will communicate with a telephone that is anywhere within the vehicle. However, covering the hand held phone or the hands-free phone module with a metal object may block the signal. The system will recognize up to seven telephones, each of which is given a spoken identification by the user during the setup process. The system includes Spanish voice recognition in addition to English.

Two buttons on the rearview mirror, identified with ISO icons, control the system: A ″phone″ button turns the system on and off; a ″voice recognition″ (or voice command) button prompts the hands-free system to listen for a voice command.

OPERATION

TELECOMMUNICATION

Two buttons on the rearview mirror, identified with ISO icons, control the system: A ″phone″ button turns the system on and off; a ″voice recognition″ (or voice command) button prompts the hands-free system to listen for a voice command. The system includes the following features:

- Phone book - Stores telephone numbers for later recall by name or other verbal identification, called a voice tag, and memory location.
- Four memory locations - Home, Work, Cellular and Pager. A maximum of 32 unique names or voice tags may be stored at the same time, with a different number in each of the four memory locations.
- Voice tag dialing - Dials the number associated with a voice tag and memory location.
- Digit dialing - Dials the telephone number by recognizing the names of the digits as they are spoken.
- Receiving calls - A voice prompt notifies the user of an incoming call. A voice response accepts or rejects the call without manual intervention.
- Privacy Mode - Switches the call to the hand-held telephone and the hands-free system and back again using the “voice recognition” (or “voice command”) button and a voice command, if desired.

HANDS FREE MODULE

REMOVAL

(1) Disconnect and isolate the battery negative cable.

(2) Remove the radio (Refer to 8 - ELECTRICAL/ AUDIO/RADIO - REMOVAL).

(3) Remove the mounting fasteners (Fig. 1).

(4) Disconnect the electrical harness connector and remove module.

INSTALLATION

(1) Connect electrical harness connector and position module.

(2) Install mounting fasteners.

(3) Install radio (Refer to 8 - ELECTRICAL/AUDIO/RADIO - INSTALLATION).

(4) Connect battery negative cable.

WIRING DIAGRAM INFORMATION

DESCRIPTION

DESCRIPTION - HOW TO USE WIRING DIAGRAMS

DaimlerChrysler Corporation wiring diagrams are designed to provide information regarding the vehicles wiring content. In order to effectively use the wiring diagrams to diagnose and repair DaimlerChrysler Corporation vehicles, it is important to understand all of their features and characteristics.

Diagrams are arranged such that the power (B+) side of the circuit is placed near the top of the page, and the ground (B-) side of the circuit is placed near the bottom of the page (Fig. 1).

All switches, components, and modules are shown in the at rest position with the doors closed and the key removed from the ignition (Fig. 2).

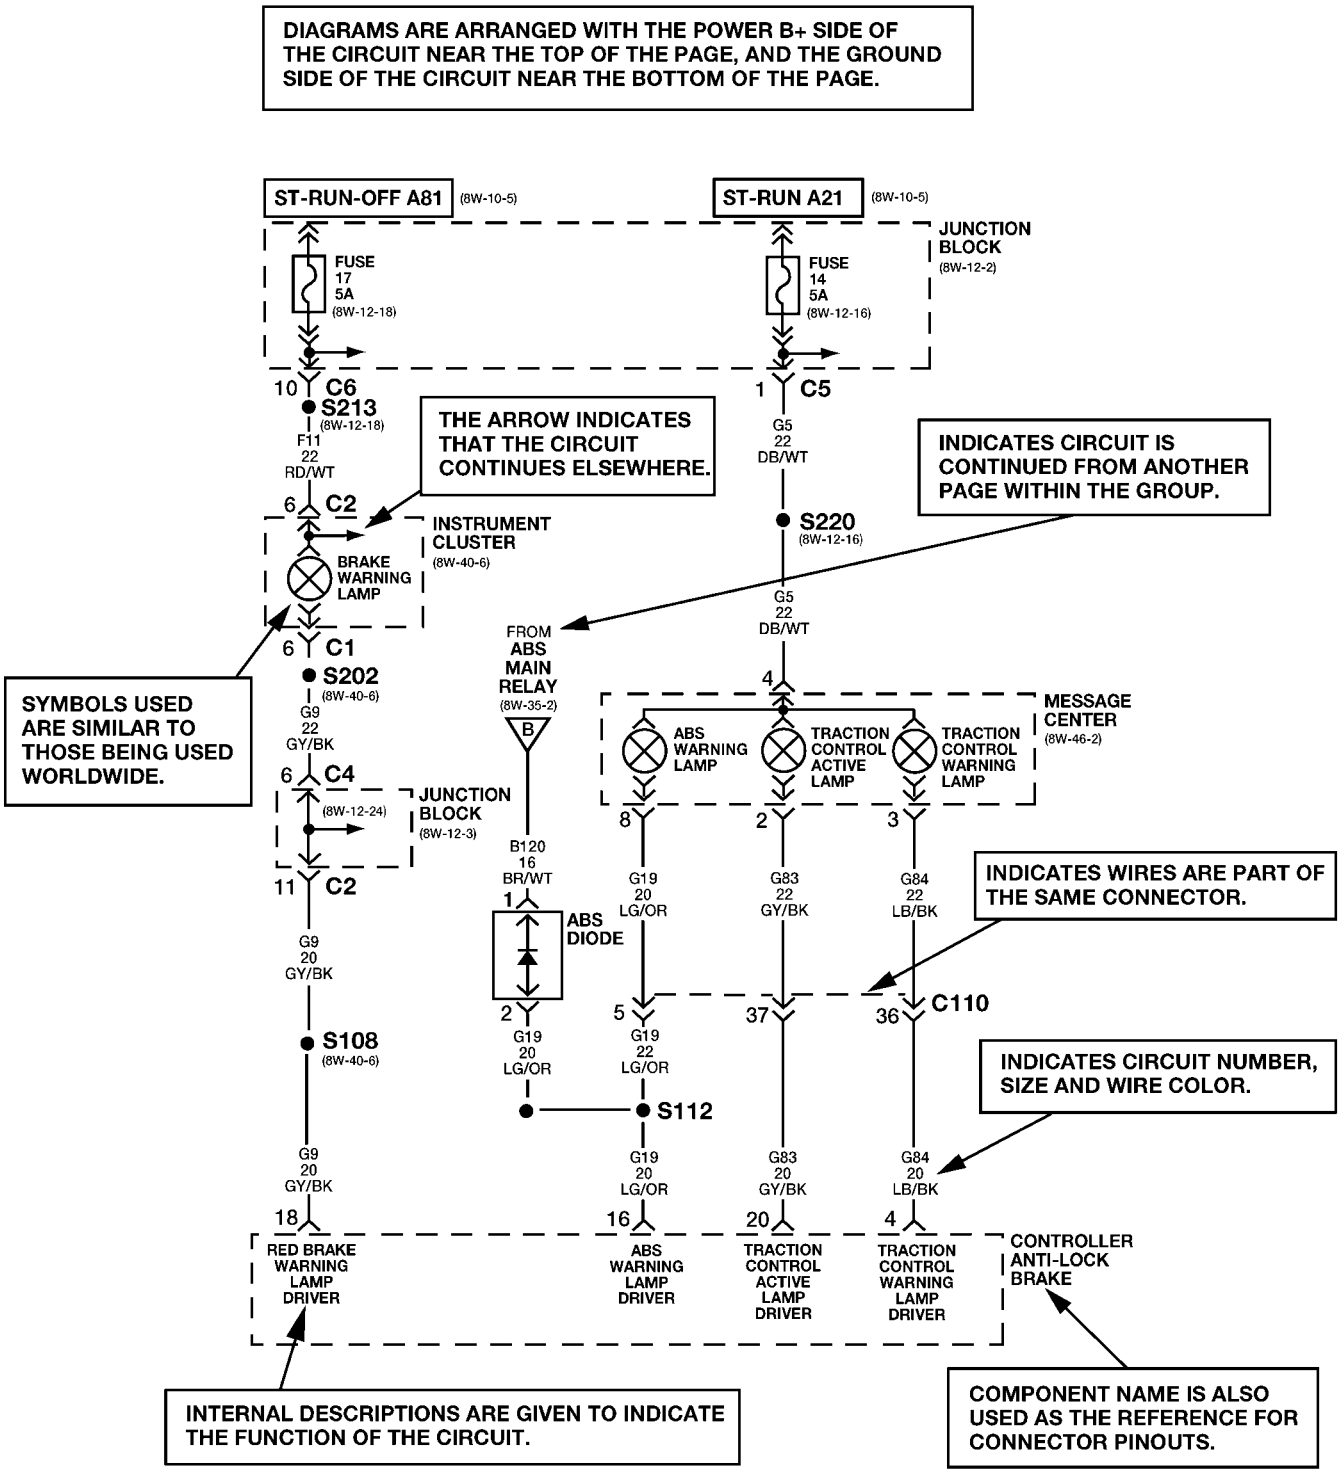
Components are shown two ways. A solid line around a component indicates that the component is complete. A dashed line around the component indicates that the component is being shown is not complete. Incomplete components have a reference number to indicate the page where the component is shown complete.

It is important to realize that no attempt is made on the diagrams to represent components and wiring as they appear on the vehicle. For example, a short piece of wire is treated the same as a long one. In addition, switches and other components are shown as simply as possible, with regard to function only.

SYMBOLS

International symbols are used throughout the wiring diagrams. These symbols are consistent with those being used around the world (Fig. 3).

WIRING DIAGRAM INFORMATION (Continued)



The System shown here is an EXAMPLE ONLY. It does not represent the actual circuit shown in the WIRING DIAGRAM SECTION.

80c06d01

Fig. 1 WIRING DIAGRAM EXAMPLE 1

WIRING DIAGRAM INFORMATION (Continued)

TERMINOLOGY

This is a list of terms and definitions used in the wiring diagrams.

LHD . . . . . Left Hand Drive Vehicles
RHD . . . . . Right Hand Drive Vehicles
ATX . . Automatic Transmissions-Front Wheel Drive
MTX . . . Manual Transmissions-Front Wheel Drive
AT . . . . Automatic Transmissions-Rear Wheel Drive
MT . . . . . Manual Transmissions-Rear Wheel Drive
SOHC . . . . . Single Over Head Cam Engine
DOHC . . . . . Double Over Head Cam Engine
Export . . Vehicles Built For Sale In Markets Other Than North America
Except Export . . . . Vehicles Built For Sale In North America

DESCRIPTION - CIRCUIT INFORMATION

Each wire shown in the diagrams contains a code which identifies the main circuit, part of the main circuit, gage of wire, and color (Fig. 4).

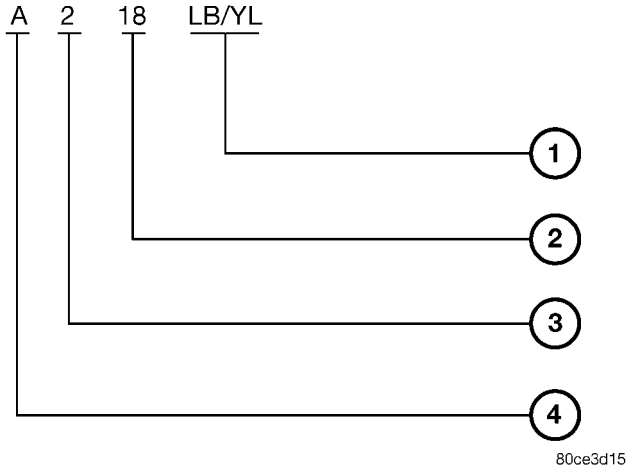

Fig. 4 WIRE CODE IDENTIFICATION

1 - COLOR OF WIRE (LIGHT BLUE WITH YELLOW TRACER
2 - GAGE OF WIRE (18 GAGE)
3 - PART OF MAIN CIRCUIT (VARIES DEPENDING ON EQUIPMENT)
4 - MAIN CIRCUIT IDENTIFICATION

WIRE COLOR CODE CHART

COLOR CODE	COLOR
BL	BLUE
BK	BLACK
BR	BROWN
DB	DARK BLUE
DG	DARK GREEN
GY	GRAY
LB	LIGHT BLUE
LG	LIGHT GREEN
OR	ORANGE
PK	PINK
RD	RED
TN	TAN
VT	VIOLET
WT	WHITE
YL	YELLOW
*	WITH TRACER

WIRING DIAGRAM INFORMATION (Continued)

DESCRIPTION - CIRCUIT FUNCTIONS

All circuits in the diagrams use an alpha/numeric code to identify the wire and it's function. To identify which circuit code applies to a system, refer to the Circuit Identification Code Chart. This chart shows the main circuits only and does not show the secondary codes that may apply to some models.

CIRCUIT IDENTIFICATION CODE CHART

CIRCUIT	FUNCTION
A	BATTERY FEED
B	BRAKE CONTROLS
C	CLIMATE CONTROLS
D	DIAGNOSTIC CIRCUITS
E	DIMMING ILLUMINATION CIRCUITS
F	FUSED CIRCUITS
G	MONITORING CIRCUITS (GAUGES)
H	MULTIPLE
I	NOT USED
J	OPEN
K	POWERTRAIN CONTROL MODULE
L	EXTERIOR LIGHTING
M	INTERIOR LIGHTING
N	MULTIPLE
O	NOT USED
P	POWER OPTION (BATTERY FEED)
Q	POWER OPTIONS (IGNITION FEED)
R	PASSIVE RESTRAINT
S	SUSPENSION/STEERING
T	TRANSMISSION/TRANSAXLE/ TRANSFER CASE
U	OPEN
V	SPEED CONTROL, WIPER/ WASHER
W	WIPERS
X	AUDIO SYSTEMS
Y	OPEN
Z	GROUNDS

DESCRIPTION - SECTION IDENTIFICATION AND INFORMATION

The wiring diagrams are grouped into individual sections. If a component is most likely found in a particular group, it will be shown complete (all wires, connectors, and pins) within that group. For example, the Auto Shutdown Relay is most likely to be found in Group 30, so it is shown there complete. It can, however, be shown partially in another group if it contains some associated wiring.

Splice diagrams in Section 8W-70 show the entire splice and provide references to other sections the splices serves. Section 8W-70 only contains splice diagrams that are not shown in their entirety somewhere else in the wiring diagrams.

Section 8W-80 shows each connector and the circuits involved with that connector. The connectors are identified using the name/number on the diagram pages.

WIRING SECTION CHART

GROUP	TOPIC
8W-01 thru 8W-09	General information and Diagram Overview
8W-10 thru 8W-19	Main Sources of Power and Vehicle Grounding
8W-20 thru 8W-29	Starting and Charging
8W-30 thru 8W-39	Powertrain/Drivetrain Systems
8W-40 thru 8W-49	Body Electrical items and A/C
8W-50 thru 8W-59	Exterior Lighting, Wipers and Trailer Tow
8W-60 thru 8W-69	Power Accessories
8W-70	Splice Information
8W-80	Connector Pin Outs
8W-91	Connector, Ground and Splice Locations

WIRING DIAGRAM INFORMATION (Continued)

DESCRIPTION - CONNECTOR, GROUND AND SPLICE INFORMATION

CAUTION: Not all connectors are serviced. Some connectors are serviced only with a harness. A typical example might be the Supplemental Restraint System connectors. Always check parts availability before attempting a repair.

IDENTIFICATION

In-line connectors are identified by a number, as follows:

- In-line connectors located in the engine compartment are C100 series numbers
- In-line connectors located in the Instrument Panel area are C200 series numbers.
- In-line connectors located in the body are C300 series numbers.
- Jumper harness connectors are C400 series numbers.
- Grounds and ground connectors are identified with a “G” and follow the same series numbering as the in-line connectors.
- Splices are identified with an “S” and follow the same series numbering as the in-line connectors.
- Component connectors are identified by the component name instead of a number. Multiple connectors on a component use a C1, C2, etc. identifier.

LOCATIONS

Section 8W-91 contains connector/ground/splice location illustrations. The illustrations contain the connector name (or number)/ground number/splice number and component identification. Connector/ground/splice location charts in section 8W-91 reference the figure numbers of the illustrations.

The abbreviation T/O is used in the component location section to indicate a point in which the wiring harness branches out to a component. The abbreviation N/S means Not Shown in the illustrations

WARNINGS - GENERAL

WARNINGS provide information to prevent personal injury and vehicle damage. Below is a list of general warnings that should be followed any time a vehicle is being serviced.

WARNING: ALWAYS WEAR SAFETY GLASSES FOR EYE PROTECTION.

WARNING: USE SAFETY STANDS ANYTIME A PROCEDURE REQUIRES BEING UNDER A VEHICLE.

WARNING: BE SURE THAT THE IGNITION SWITCH ALWAYS IS IN THE OFF POSITION, UNLESS THE PROCEDURE REQUIRES IT TO BE ON.

WARNING: SET THE PARKING BRAKE WHEN WORKING ON ANY VEHICLE. AN AUTOMATIC TRANSMISSION SHOULD BE IN PARK. A MANUAL TRANSMISSION SHOULD BE IN NEUTRAL.

WARNING: OPERATE THE ENGINE ONLY IN A WELL-VENTILATED AREA.

WARNING: KEEP AWAY FROM MOVING PARTS WHEN THE ENGINE IS RUNNING, ESPECIALLY THE FAN AND BELTS.

WARNING: TO PREVENT SERIOUS BURNS, AVOID CONTACT WITH HOT PARTS SUCH AS THE RADIATOR, EXHAUST MANIFOLD(S), TAIL PIPE, CATALYTIC CONVERTER AND MUFFLER.

WARNING: DO NOT ALLOW FLAME OR SPARKS NEAR THE BATTERY. GASES ARE ALWAYS PRESENT IN AND AROUND THE BATTERY.

WARNING: ALWAYS REMOVE RINGS, WATCHES, LOOSE HANGING JEWELRY AND AVOID LOOSE CLOTHING.

DIAGNOSIS AND TESTING - WIRING HARNESS

TROUBLESHOOTING TOOLS

When diagnosing a problem in an electrical circuit there are several common tools necessary. These tools are listed and explained below.

- Jumper Wire - This is a test wire used to connect two points of a circuit. It can be used to bypass an open in a circuit.

WARNING: NEVER USE A JUMPER WIRE ACROSS A LOAD, SUCH AS A MOTOR, CONNECTED BETWEEN A BATTERY FEED AND GROUND.

- Voltmeter - Used to check for voltage on a circuit. Always connect the black lead to a known good ground and the red lead to the positive side of the circuit.

CAUTION: Most of the electrical components used in today’s vehicles are Solid State. When checking voltages in these circuits, use a meter with a 10 - megohm or greater impedance rating.

WIRING DIAGRAM INFORMATION (Continued)

• Ohmmeter - Used to check the resistance between two points of a circuit. Low or no resistance in a circuit means good continuity.

CAUTION: Most of the electrical components used in today's vehicles are Solid State. When checking resistance in these circuits use a meter with a 10 - megohm or greater impedance rating. In addition, make sure the power is disconnected from the circuit. Circuits that are powered up by the vehicle's electrical system can cause damage to the equipment and provide false readings.

• Probing Tools - These tools are used for probing terminals in connectors (Fig. 5). Select the proper size tool from Special Tool Package 6807, and insert it into the terminal being tested. Use the other end of the tool to insert the meter probe.

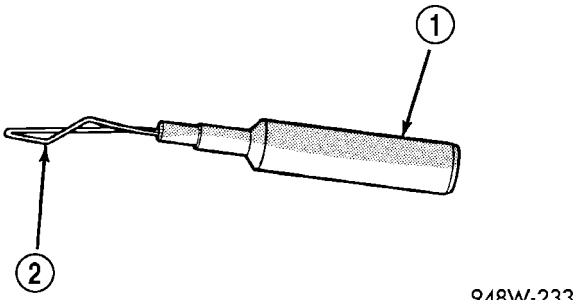

Fig. 5 PROBING TOOL

1 - SPECIAL TOOL 6801
2 - PROBING END

INTERMITTENT AND POOR CONNECTIONS

Most intermittent electrical problems are caused by faulty electrical connections or wiring. It is also possible for a sticking component or relay to cause a problem. Before condemning a component or wiring assembly, check the following items.

• Connectors are fully seated
• Spread terminals, or terminal push out
• Terminals in the wiring assembly are fully seated into the connector/component and locked into position
• Dirt or corrosion on the terminals. Any amount of corrosion or dirt could cause an intermittent problem
• Damaged connector/component casing exposing the item to dirt or moisture
• Wire insulation that has rubbed through causing a short to ground
• Some or all of the wiring strands broken inside of the insulation
• Wiring broken inside of the insulation

TROUBLESHOOTING WIRING PROBLEMS

When troubleshooting wiring problems there are six steps which can aid in the procedure. The steps are listed and explained below. Always check for non-factory items added to the vehicle before doing any diagnosis. If the vehicle is equipped with these items, disconnect them to verify these add-on items are not the cause of the problem.

(1) Verify the problem.
(2) Verify any related symptoms. Do this by performing operational checks on components that are in the same circuit. Refer to the wiring diagrams.
(3) Analyze the symptoms. Use the wiring diagrams to determine what the circuit is doing, where the problem most likely is occurring and where the diagnosis will continue.
(4) Isolate the problem area.
(5) Repair the problem area.
(6) Verify the proper operation. For this step, check for proper operation of all items on the repaired circuit. Refer to the wiring diagrams.

STANDARD PROCEDURE

STANDARD PROCEDURE - ELECTROSTATIC DISCHARGE (ESD) SENSITIVE DEVICES

All ESD sensitive components are solid state and a symbol (Fig. 6) is used to indicate this. When handling any component with this symbol, comply with the following procedures to reduce the possibility of electrostatic charge build up on the body and inadvertent discharge into the component. If it is not known whether the part is ESD sensitive, assume that it is.

(1) Always touch a known good ground before handling the part. This should be repeated while handling the part and more frequently after sliding across a seat, sitting down from a standing position, or walking a distance.
(2) Avoid touching electrical terminals of the part, unless instructed to do so by a written procedure.
(3) When using a voltmeter, be sure to connect the ground lead first.
(4) Do not remove the part form it's protective packing until it is time to install the part.
(5) Before removing the part from it's pakage, ground the pakage to a known good ground on the vehicle.

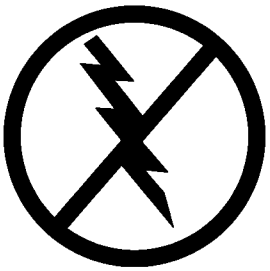

Fig. 6 ELECTROSTATIC DISCHARGE SYMBOL

WIRING DIAGRAM INFORMATION (Continued)

STANDARD PROCEDURE - TESTING OF VOLTAGE POTENTIAL

(1) Connect the ground lead of a voltmeter to a known good ground (Fig. 7).

(2) Connect the other lead of the voltmeter to the selected test point. The vehicle ignition may need to be turned ON to check voltage. Refer to the appropriate test procedure.

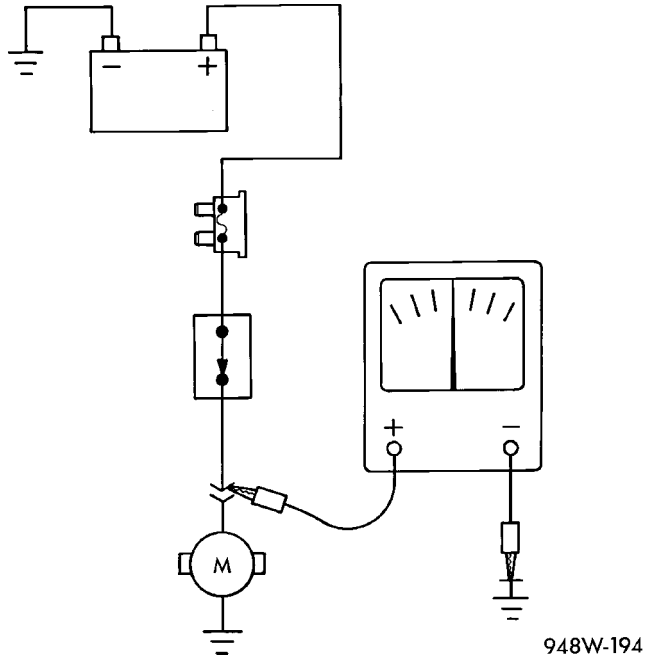

Fig. 7 TESTING FOR VOLTAGE POTENTIAL

STANDARD PROCEDURE - TESTING FOR CONTINUITY

(1) Remove the fuse for the circuit being checked or, disconnect the battery.

(2) Connect one lead of the ohmmeter to one side of the circuit being tested (Fig. 8).

(3) Connect the other lead to the other end of the circuit being tested. Low or no resistance means good continuity.

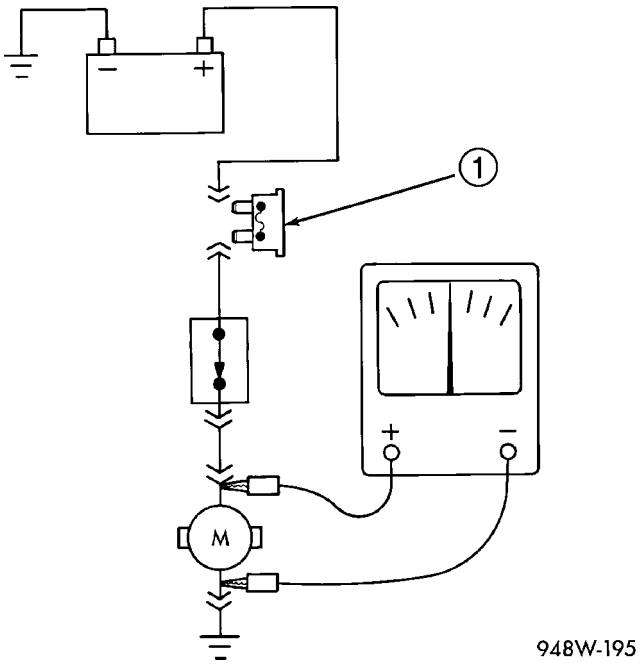

Fig. 8 TESTING FOR CONTINUITY

1 - FUSE REMOVED FROM CIRCUIT

STANDARD PROCEDURE - TESTING FOR A SHORT TO GROUND

(1) Remove the fuse and disconnect all items involved with the fuse.

(2) Connect a test light or a voltmeter across the terminals of the fuse.

(3) Starting at the fuse block, wiggle the wiring harness about six to eight inches apart and watch the voltmeter/test lamp.

(4) If the voltmeter registers voltage or the test lamp glows, there is a short to ground in that general area of the wiring harness.

WIRING DIAGRAM INFORMATION (Continued)

STANDARD PROCEDURE - TESTING FOR A SHORT TO GROUND ON FUSES POWERING SEVERAL LOADS

(1) Refer to the wiring diagrams and disconnect or isolate all items on the suspected fused circuits.

(2) Replace the blown fuse.

(3) Supply power to the fuse by turning ON the ignition switch or re-connecting the battery.

(4) Start connecting or energizing the items in the fuse circuit one at a time. When the fuse blows the circuit with the short to ground has been isolated.

STANDARD PROCEDURE - TESTING FOR A VOLTAGE DROP

(1) Connect the positive lead of the voltmeter to the side of the circuit closest to the battery (Fig. 9).

(2) Connect the other lead of the voltmeter to the other side of the switch, component or circuit.

(3) Operate the item.

(4) The voltmeter will show the difference in voltage between the two points.

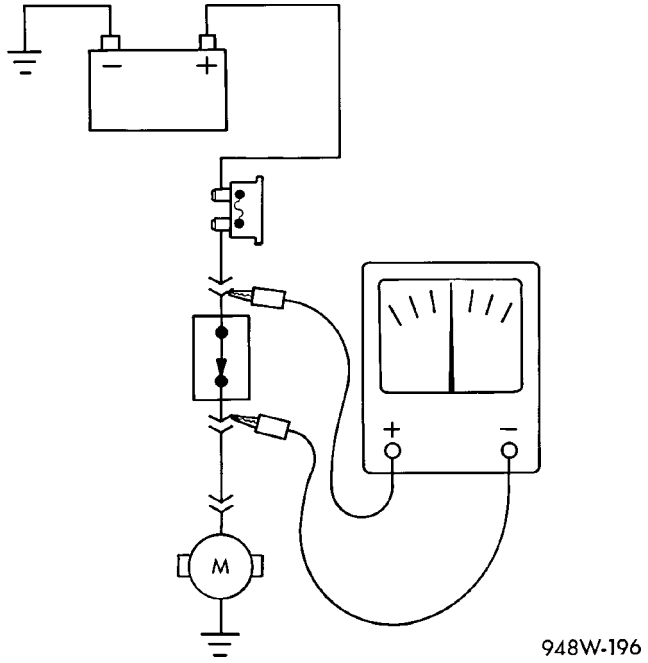

Fig. 9 TESTING FOR VOLTAGE DROP

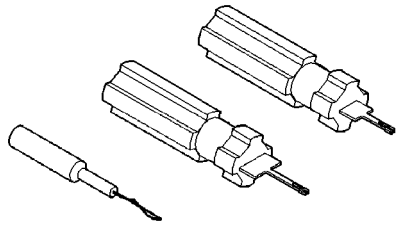
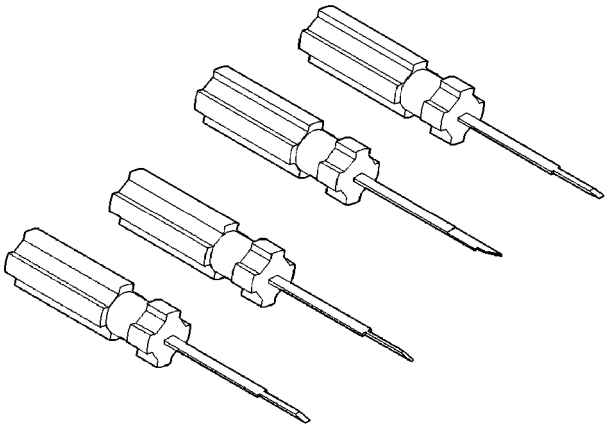
SPECIAL TOOLS

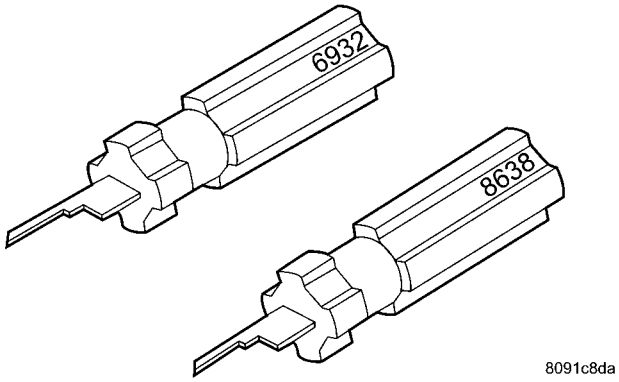
WIRING/TERMINAL



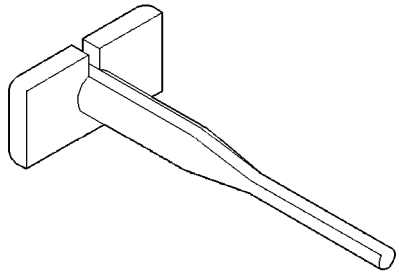
PROBING TOOL PACKAGE 6807



TERMINAL PICK TOOL SET 6680



TERMINAL REMOVING TOOLS 6932 AND 8638



TERMINAL REMOVING TOOL 6934

CONNECTOR

REMOVAL

(1) Disconnect battery.

(2) Release Connector Lock (Fig. 10).

(3) Disconnect the connector being repaired from its mating half/component.

(4) Remove the dress cover (if applicable) (Fig. 10).

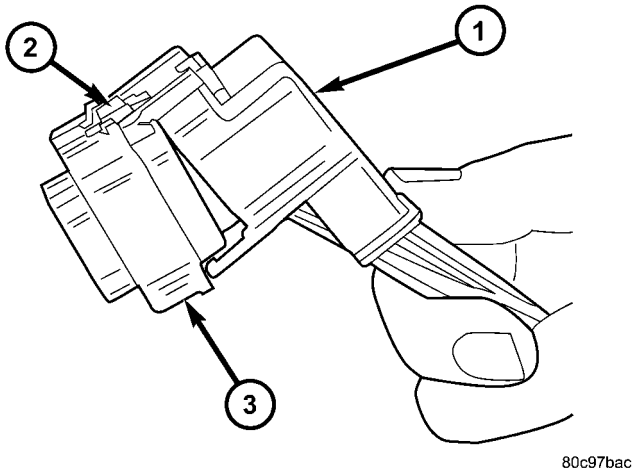


Fig. 10 REMOVAL OF DRESS COVER

1 - DRESS COVER
2 - CONNECTOR LOCK
3 - CONNECTOR

(5) Release the Secondary Terminal Lock, if required (Fig. 11).

(6) Position the connector locking finger away from the terminal using the proper special tool. Pull on the wire to remove the terminal from the connector (Fig. 12).

INSTALLATION

(1) Insert the removed terminal in the same cavity on the repair connector.

(2) Repeat steps for each terminal in the connector, being sure that all wires are inserted into the proper cavities. For additional connector pin-out identification, refer to the wiring diagrams.

(3) When the connector is re-assembled, the secondary terminal lock must be placed in the locked position to prevent terminal push out.

(4) Replace dress cover (if applicable).

(5) Connect connector to its mating half/component.

(6) Connect battery and test all affected systems.

CONNECTOR (Continued)

10 - SPECIAL TOOL 6934
11 - TYCO CONNECTOR
12 - SPECIAL TOOL 8638

DIODE

REMOVAL

(1) Disconnect the battery.

(2) Locate the diode in the harness, and remove the protective covering.

(3) Remove the diode from the harness, pay attention to the current flow direction (Fig. 13).

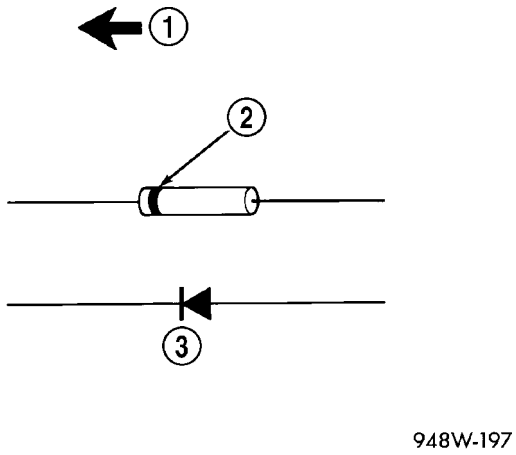

Fig. 13 DIODE IDENTIFICATION

1 - CURRENT FLOW
2 - BAND AROUND DIODE INDICATES CURRENT FLOW
3 - DIODE AS SHOWN IN THE DIAGRAMS

INSTALLATION

(1) Remove the insulation from the wires in the harness. Only remove enough insulation to solder in the new diode.

(2) Install the new diode in the harness, making sure current flow is correct. If necessary, refer to the appropriate wiring diagram for current flow (Fig. 13).

(3) Solder the connection together using rosin core type solder only. **Do not use acid core solder.**

(4) Tape the diode to the harness using electrical tape. Make sure the diode is completely sealed from the elements.

(5) Re-connect the battery and test affected systems.

TERMINAL

REMOVAL

(1) Follow steps for removing terminals described in the connector removal section.

(2) Cut the wire 6 inches from the back of the connector.

INSTALLATION

(1) Select a wire from the terminal repair kit that best matches the color and gage of the wire being repaired.

(2) Cut the repair wire to the proper length and remove one–half (1/2) inch of insulation.

(3) Splice the repair wire to the wire harness (see wire splicing procedure) .

(4) Insert the repaired wire into the connector.

(5) Install the connector locking wedge, if required, and reconnect the connector to its mating half/component.

(6) Re-tape the wire harness starting at 1–1/2 inches behind the connector and 2 inches past the repair.

(7) Connect battery and test all affected systems.

WIRE

STANDARD PROCEDURE - WIRE SPLICING

When splicing a wire, it is important that the correct gage be used as shown in the wiring diagrams.

(1) Remove one-half (1/2) inch of insulation from each wire that needs to be spliced.

(2) Place a piece of adhesive lined heat shrink tubing on one side of the wire. Make sure the tubing will be long enough to cover and seal the entire repair area.

(3) Place the strands of wire overlapping each other inside of the splice clip (Fig. 14).

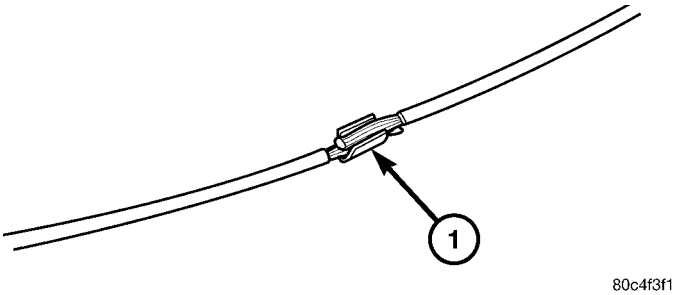

Fig. 14 SPLICE BAND

1 - SPLICE BAND

(4) Using crimping tool, Mopar p/n 05019912AA, crimp the splice clip and wires together (Fig. 15).

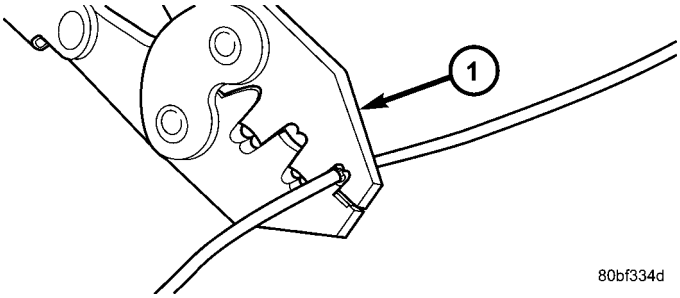

Fig. 15 CRIMPING TOOL

1 - CRIMPING TOOL

(5) Solder the connection together using rosin core type solder only (Fig. 16).

CAUTION: DO NOT USE ACID CORE SOLDER.

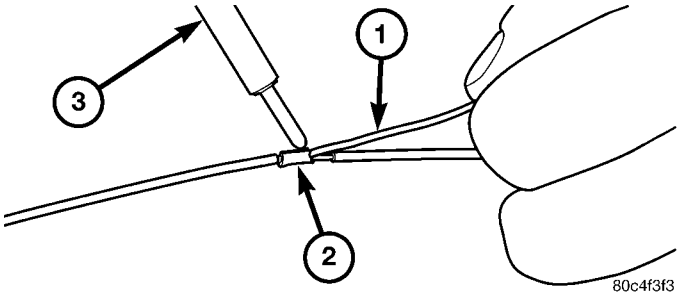

Fig. 16 SOLDER SPLICE

1 - SOLDER
2 - SPLICE BAND
3 - SOLDERING IRON

(6) Center the heat shrink tubing over the joint and heat using a heat gun. Heat the joint until the tubing is tightly sealed and sealant comes out of both ends of the tubing (Fig. 17).
